

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at <http://books.google.com/>

PREFACE TO SECOND EDITION

The first edition of this work contained the equivalent of about 160,000 words, while this edition contains more than a million. Its four-fold growth has been due not only to the filling of many gaps that formerly existed, but to the addition of certain kinds of cost data that interest engineers only. In writing the first edition, I had primarily in mind the contractor, whose concern is to know the most economical method of construction and the unit costs in every detail. While every engineer should, and many do, take as keen an interest as the contractor in itemized unit costs, all engineers are called upon, at one time or another, to give approximate preliminary estimates of costs, and these must often be furnished before the structure has been designed. For example, a hydraulic engineer may be asked the probable cost of a filter plant for a city consuming a given amount of water. He should be able to state the cost of sand filter beds per acre, covered or uncovered, and the annual cost of operation per million gallons filtered. To illustrate again: A railway engineer finds that a high steel viaduct may be needed to cross a valley. He desires a rational formula by which the approximate weight of steel in such a viaduct can be computed, knowing the profile area. Or, if he plans a high timber trestle, he wants a method of approximating the number of feet board measure and the pounds of iron it will require.

In brief, the engineer needs frequently to ascertain the number of units in a structure of a given class and size, as well as the unit costs; whereas the contractor is usually satisfied with data giving the itemized unit costs under stated conditions. I have tried to supply both wants in this edition.

During the last four years I have continued accumulating data on methods and costs, a large part of which have been published in *Engineering-Contracting*. When I began to make these data a feature of *Engineering-Contracting*, I received several letters expressing the hope that I should be able to continue the work of publishing such cost data, but at the same time voicing a fear that the good material would soon be exhausted. So long as men remain possessed of inventive faculties and of genius for organization, we need never fear that new and valuable cost data will be unobtainable. Management engineering is an infant science, and we shall see astonishing changes in methods of doing work, in machines used, and consequently in unit costs.

This comparatively new study of engineering costs has not only

had a pronounced effect upon methods of construction, but has already begun to work a change in designs of engineering structures. Specifications drawn by engineers who are ignorant of the items of actual unit costs are often absurd in their requirements. Hence, as a knowledge of costs spreads, we may confidently expect radical changes in designs and in specifications. These changes will result in entirely new cost data, so that a dearth of this sort of information is not to be expected from now on.

I wish to acknowledge my indebtedness to the files of the following periodicals and society transactions:

Engineering-Contracting, Engineering News, Engineering Record, Railway Age-Gazette, Electric Railway Journal, Municipal Engineering Magazine, Municipal Journal and Engineer, Good Roads Magazine, Engineering Magazine, American Society of Civil Engineers, Western Society of Engineers, Association of Engineering Societies, Canadian Society of Civil Engineers, Illinois Society of Engineers, Engineers' Society of Western Pennsylvania, Engineers' Club of Philadelphia, New England Water Works Association, American Water Works Association, American Railway Engineering and Maintenance of Way Association, American Association of Railway Superintendents of Bridges and Buildings, and the Institution of Civil Engineers.

HALBERT P. GILLETTE

New York, March 14, 1910.

PREFACE TO FIRST EDITION.

Four years ago I announced in my little book, "Economics of Road Construction," that I had in preparation a handbook of cost data for engineers and contractors. At that time this handbook had been under way for eight years, and it seemed nearly ready for publication; but other duties prevented a speedy finishing of the task. The delay, however, has been fortunate in that I have added very much to my knowledge of the general subject. In the meantime, two books have grown out of the original manuscript, namely, my books on earthwork and on rock excavation. The writing of these two books has better fitted me for the writing of this book, and has put me in touch with many engineers and contractors who have generously furnished additional cost data.

So far as I know, this is the first book on engineering cost data ever published. There are "price books" written for house builders, but they are essentially what their name implies—books on prices of materials and contract prices. This book differs from all such works, aside from the fact that it covers the whole field of civil engineering, in that it is a book in which costs are analyzed and discussed. A contract price is one thing, a contract cost is an entirely different thing, in spite of the common confusion of these terms. In order fully to understand any analysis of unit costs it is necessary to have a detailed description of the methods used in construction and operation. Hence, although itemized cost data

occupy many scores of pages in this book, there are many more scores of pages devoted to descriptions of how the work was done, the organization of the forces, and the machines used. The records, in all cases, are actual records taken from every available source of published information, from personal letters sent by engineers and contractors and from my own records.

It is often said that cost data are of no value to an inexperienced man. Generally the men who make such statements are themselves possessed of few records of cost, or use this argument as an excuse for not making public such records as they do possess. The very secretiveness of men having cost data which they refuse to make public, nullifies their statement that such data can be of no use to others.

We also hear it argued that conditions vary so widely that grave errors occur when an attempt is made to apply published cost data. Those who have not been trained to study the conditions affecting costs are likely to make serious blunders in any case; but, if this book is in even a slight degree what it aims to be, it will be of greatest benefit to just such men; for it will indicate to them how to analyze costs and how to study methods of performing work economically.

Many of the erroneous ideas about the value of cost recording arise from a confusion of the term cost with the term price. This is not a handbook of prices, although many prices are given. I could have filled ten volumes with prices, and with summaries of costs written by engineers who have failed to state rates of wages and conditions under which the work was performed. But, a short time after publication, all such matter is hardly worth the ink that it is printed with, since wages and prices are subject to constant change.

The attention of contractors is called to the first part of the book in which systems of cost keeping are described. I have outlined what I believe to be some of the best systems of cost keeping. Samples of other record cards and methods than my own are shown; for my purpose has been to elucidate principles, rather than to exploit pet theories as to business management and accounting.

HALBERT P. GILLETTE.

New York, Sept. 1, 1905.

NOTICE TO AUTHORS

Authors of text books have quoted freely from the first edition of this book, often without securing permission. While we follow a liberal policy in the matter of permitting quotations, both from our books and from the pages of *Engineering-Contracting* (which is also a copyrighted publication), we expect authors to communicate with us, indicating what they desire to quote.

THE MYRON C. CLARK PUBLISHING CO.

CONTENTS.

	Page
INTRODUCTION	1
SECTION I.— <i>Principles of Engineering Economics and Cost Keeping</i>	7
Definitions.—Compound Interest Tables.—Sinking Fund Tables.—Present Worth of Annuity.—References and Cross-References.—Identity of Machine and Engineering Structure.—Problem I. Which of Two New Machines (or Structures) to Select.—Problem II. When to Retire an Old Machine in Favor of an Improved or Larger One.—The Life of a Machine or Structure and the Growth of Annual Repairs.—Problem III. To Determine When Repairs Have Grown So Great as to Justify Renewal.—Straight Line Formula of Depreciation.—The Bastard Straight Line Formula of Depreciation.—Sinking Fund Formula of Depreciation.—The Unit Cost Depreciation Formula.—Physical Property Valuations.—Going Concern Value.—Commercial Valuations.—How to Prepare Estimates and Bids.—A Schedule of Items of Cost.—Plant Expense.—Cost of Superintendence and General Expense.—Percentage to Allow for Contingencies.—Percentage to Allow for Profit.—Causes of Underestimates.—Indexing Contract Prices.—Unbalanced Bids.—Surety Company Bonds.—Reasons Why Contract Work Is the Most Economic Method of Doing Public Work.—Thomas Telford on the Day Labor System.—The Opinions of Members of the Am. Soc. C. E. on the Day Labor System.—The Metcalf and Eddy Report on the Day Labor System in Boston.—Mr. S. Whinery's Report on the Day Labor System in Boston.—Experience with Day Labor on the Chicago Main Drainage Canal and at Panama.—Subletting Work and Purchasing Materials.—Instructions to Superintendents and Foremen.—The Ten Laws of Management.—1. The Law of Sub-Division of Duties.—2. The Law of Educational Supervision.—3. The Law of Co-Ordination.—4. The Law of Standard Performance Based on Motion Timing.—5. The Law of Divorce of Planning from Performance.—6. The Law of Regular Unit Cost Reports.—7. The Law of Reward Increasing with Increased Performance.—8. The Law of Prompt Reward.—9. The Law of Competition.—10. The Law of Managerial Dignity.—Measuring the Output of Workmen.—Units for Concrete Work.—Two or More Units for the Same Class of Work.—Uniformity of Units of Measurement.—Units of Transportation.—Recording Single Units.—Record Cards	

Attached to Each Piece of Work.—Measurements of Length.—Measurements of Area.—Measurements of Volume.—Measurements of Weight.—Functional Units of Measure.—Key Units of Measure.—Key Units on Drawings.—Keys Marked on Separate Members.—Conclusion.—Cost Keeping.—Cost Keeping Defined.—Differences Between Cost Keeping and Bookkeeping.—Time Keeping Defined.—Daily Cost Reports, By Whom Made.—Written Card vs. Punch Card Reports.—Time Cards That Show Changes of Occupation.—Individual Record Cards.—Kind of Punches to Use.—Size and Kind of Daily Report Cards.—Foreman's Diary.—Designing Punch Card Reports.—Record Cards Accompanying Each Piece of Work.—Store Keeper's Reports.—Reports on Materials and Supplies.—Cost Charts.—Progress Charts.—Methods of Payment in Proportion to Performance.—Profit Sharing.—Piece Rate System.—The Bonus System.—The Differential Piece Rate System.—The Differential Bonus.—Task Work with a Bonus.—The Premium Plan.—Principles Governing the Fixing of a Piece Rate or Bonus.—Benefits of the Bonus System.—Time Cards and Time Books.—Recording Work by Minute Hand Observations.

SECTION II.—*Earth Excavation*..... 119

Magnitude of the Subject.—Earth Measurement.—Earth Shrinkage.—Kinds of Earth.—Definitions of Haul and Lead.—Work of Teams.—Cost of Plowing.—Cost of Picking and Shoveling.—Cost of Trimming, Rolling, Etc.—Cost of Wheelbarrow Work.—Cost by Wagons.—Cost by Drag Scrapers.—Cost by Wheel Scrapers.—Cost by Fresno Scrapers.—Cost by Elevating Graders.—Steam Shovel Data.—Hauling with Dinkeys.—Summary of the Cost of Steam Shovel Work.—Cost of Digging a Well or Cesspool.—Cost of Trenching, Cross-References.—Cost of Backfilling a Trench with a Scraper.—Prices of Drainage Ditch Work.—Cost of Boring Test Holes in Earth.—Cost of Wash Borings on a Canal Survey.—Cost of Wash Drill Borings on a Canal Survey.—Cost of Boring Test Holes.—Cost of Testing for Bridge Foundations.—Cost of Making Test Borings, Ill., Etc.—Cost of Test Borings with Wood Augers.—Cost of Drilling Test Holes with a Well Driller.—Cost of Diamond Drilling, Cross-References.—Cost of Sinking a Well.—References and Cross-References on Earthwork.

SECTION III.—*Rock Excavation, Quarrying and Crushing*.... 171

Weight and Voids.—Voids in Broken Stone and Gravel.—Weight and Voids in Crushed Limestone.—Settlement of Crushed Stone in Wagons.—Weight of Crushed Stone in Wagons and Cars.—The Per Cent of Voids in Railway Embankments.—Voids in Rock Blasted under Water.—Measurement of Rock.—Kinds of Hand Drills.—Cost of Hammer Drilling.—Cost of Hand Drilling in Granite.—Cost

of Churn Drilling.—Sizes of Air Drills.—Data as to Rock Drills.—Test of Air Consumption at the Rose Deep Mine.—Tables of Air Consumption.—Steam Consumption.—Gasoline Air Compressors.—Percentage of Lost Time in Drilling.—Rule for Estimating Drilling per Shift.—Rates of Drilling in Different Rocks.—Cost of Drill Repairs.—Cost of Operating Drills.—Piece Rate and Bonus System in Drilling.—Cost of Loading by Hand.—Cost of Handling Crushed Stone.—Cost of Unloading Broken Stone with a Churn.—Cost of Handling Broken Stone with a Derrick.—Cost of Loading Blasted Rock with Steam Shovels.—Cost of Hauling in Carts and Wagons.—Open-Cut Excavation.—Spacing Holes in Open-Cut Excavation.—Cost of Excavating Sandstone and Shale.—Summary of Open-Cut Data.—Cost of Excavating Gneiss, New York City.—Cost of Gneiss Excavation for Dams.—Summary of Costs on Chicago Canal.—Trenching in Rock.—Cost of Drilling and Blasting in Trenches.—Cost of Quarrying and Crushing Trap Rock.—Cost of Crushing at Newton, Mass.—Cost of Quarrying and Crushing Quartzite.—Cost of Quarrying and Crushing Limestone for Macadam.—Price of Road Building Plant.—Cost of Jaw Crusher Renewals.—Cost of Quarrying and Crushing Limestone, Missouri.—Cost of Crushing and Hauling Cobblestones.—Cost of Quarrying and Crushing Trap and Ballasting, D. L. & W. Ry.—Cost of Quarrying, Crushing and Ballasting, and Life of Ballast.—Cost of Crushing with City Plant, Boston.—Data on Jaw Crushers.—Data on Gyratory Crushers.—Cost of Breaking Stone by Hand.—Diamond Drilling.—Price of Diamonds.—Water Required.—Price of Diamond Drills.—Cost of Diamond Drilling in Virginia.—Cost of Diamond Drilling in Lehigh Valley.—Cost of Diamond Drilling on Croton Aqueduct.—Cost of Hand Diamond Drilling in Arizona.—Cost of Diamond Drilling in Pennsylvania.—Consumption of Diamonds in Drilling, Tennessee.—Cost of Diamond Drilling in British Columbia.—Cost of Core Drilling with a Well Driller.—Cost of Diamond Drilling and Wash Borings Near New York City.—Rock Excavating Using Well Drills.—Cost of an Artesian Well.—Cost of Drilling Limestone with a Well Drill, for a Quarry.—Cost of Drilling Rock with a Well Drill.—Cost of Drilling Copper Ore with Well Drills.—Cost of Tunneling, Shaft Sinking and Mining, Cross-References.—Cost of Subaqueous Rock Excavation.—Cost of Chamber Blasting.

SECTION IV.—Roads, Pavements and Walks..... 252

Definitions.—Cross-References to Excavation and Rock Crushing.—Units Used in Measuring Macadam.—Items of Cost of Macadam.—Quantity of Stone and Binder Required for Macadam.—Cost of Loading Stone from Cars into Wagons.—Cost of Loading Stone from Bins into Wagons.—

Cost of Hauling Stone in Wagons.—Cost of Spreading Stone by Hand.—Cost of Spreading Stone with a Leveler or Grader.—Cost of Rolling.—Cost of Sprinkling.—Summary of Cost of Macadam.—Estimating the Cost of Macadam, New York State.—Prices Allowed for Extra Work on New York State Roads.—Macadam Road Prices in Massachusetts.—Per Cent of Engineering for Road Construction.—Cost of Macadam Roads, New Jersey.—Cost of a Limestone Macadam Road, Buffalo, N. Y.—Cost of a Sandstone and Trap Macadam, Rochester, N. Y.—Cost of Macadam Roads, Illinois.—Data on Depreciation and Repairs of Steam Rollers.—Cost of Steam Roller Repairs in Massachusetts.—Cost of Scarifying Macadam by Hand.—Cost of Scarifying with a Machine.—Cost of Scarifying Macadam, Rhode Island.—Cost of Resurfacing Old Limestone Macadam.—Cost of Repairing Sandstone Macadam, Albion, N. Y.—Cost of Resurfacing Macadam and Data on Compression of Broken Stone.—Cost of Repairing Macadam in Ireland.—Cost of Maintaining Macadam Roads, Massachusetts.—Cost of Using Calcium Chloride as a Dust Preventative.—Cost of Tarring Macadam, Michigan.—Cost of Tarring Macadam, Massachusetts.—Cost of Tarring Macadam, Tennessee.—Cost of Oiling Macadam, Tennessee.—Cost of Oiled Earth Road, Arkansas.—Cost of Oiling Macadam, New York State.—Cost of Oiling Macadam, Kansas City, Mo.—Cost of Tar Macadam, Massachusetts.—Cost of Tar Macadam, Duluth, Minn.—Cost of Asphalt Macadam, Redlands, Cal.—Cost of Petrolithic Macadam.—Cost of Petrolithic Road.—Cost of Telford Roads, New Jersey.—Cost of Sand-Clay Roads.—Cost of Sand-Clay Road, Iowa.—Cost of Cinder-Clay Road, Iowa.—Cost of Burnt Clay Roads.—Cost of Maintaining Earth Roads by Dragging.—Cost of Making a Corduroy Road.—Cost of Gravel Street, Michigan.—Cross-References on Cost of Grading Roads.—Cost of Grading a Road, New York.—Cost of Grading a Road, Maryland.—Cost of Grading a Road with a Road Machine, Michigan.—Average Prices of Pavements in 100 Representative Cities, Together with Wages of Labor and Prices of Materials.—Cost of Pavements in 50 Cities.—Prices for Estimating Street Work.—Cost of Unloading and Hauling Bricks.—Gravity Conveyor for Handling Paving Bricks.—Cost of Laying Bricks.—Summary of Cost of Brick Pavement.—Cost of Filling Joints of Brick Pavement.—Number and Weight of Paving Brick per Sq. Yd.—Cost of a Brick Pavement, Illinois.—Cost of \$0,000 Sq. Yds. of Brick Pavement, Iowa.—Cost of Laying Brick Pavement, Indiana.—Cost of Laying Brick Pavement, New York.—Bricks Laid Per Man Per Day, Michigan.—Cost of a Brick Pavement, Minneapolis.—Cost of a Brick Pavement, Tennessee.—Cost of a Brick Pavement, Maryland.—Cost of Removing, Chipping Off Tar and Relaying Brick.—Cost of

Removing and Replacing a Brick Pavement.—Cost of Laying a Stone Block Pavement, St. Paul.—Cost of Stone Block Pavement, Rochester, N. Y.—Cost of Stone Block Pavement, Baltimore.—Cost of Granite Block Pavement, New York City.—Cost of Laying Block Pavement, New York City.—Cost of Granite Block Pavement, Baltimore.—Cost of Dressing Old Granite Blocks.—Cost of Removing and Relaying a Cobblestone Pavement.—Cost of Laying Asphalt Block Pavement, New York City.—Cost of Asphalt Block Pavement, Baltimore.—Cost of Creosoted Wood Block Pavement, Minneapolis.—Labor Cost of Creosoted Wood Block Pavement, Seattle.—Cost of Creosoted Wood Block Pavement, Massachusetts.—Life of Wood Block Pavement.—Cost of Asphalt Pavement in California.—Cost of 77,200 Sq. Yds. of Asphalt Pavement.—Cost of Asphalt Pavements, Winnipeg.—Cost of Laying Asphalt Pavement.—Cost of Asphalt Pavement, New York City.—Cost of Patching Asphalt, Indianapolis.—High Cost of Patching Asphalt, New Orleans.—Cost of Patching Asphalt, Marion, Ind.—High Cost of Patching Asphalt, Brooklyn.—Cost of Bitulithic and Asphalt Pavements and Repairs, Toronto.—Cost of Repairs to Asphalt Pavements, Syracuse, N. Y.—Cost of Repairs and Life of Asphalt, Washington, D. C.—Cost of Repairing Asphalt Pavement in Various American Cities.—Specific Gravity of Bitulithic and Asphalt Pavements.—Cost of Asphalt Cross Walks.—Cost of Mixing Concrete Base by Hand.—Cost of Machine Mixing and Wagon Hauling.—Cost of Mixing Concrete with a Continuous Mixer.—Cost of Concrete Pavement, Windsor, Ont.—Cost of Excavating a Concrete Base and Laying New Concrete.—Cost of Excavating an Asphalt Pavement and Its Concrete Base.—Amount of Materials for Cement Side Walks.—Cost of Cement Walks.—Cost of Cement Walk, San Francisco.—Cost of Cement Walk, Toronto.—Cost of Cement Walk, Forbes Hill Reservoir.—Cost of Acid Finish on Cement Walks.—Cost of Cement Curb and Walk, Indiana.—Cost of Cement Curb, Iowa.—Cost of Cement Curb and Gutter.—Cost of Cement Curb, Baltimore.—Cost of Cement Curb and Gutter, Ontario.—Cost of Setting Stone Curb.—Cost of Cutting and Setting Granite Curb.—Cost of Resetting Stone Curb.—Recording Cost of Street Sprinkling.—Cost of Street Sprinkling, Washington, D. C.—Cost of Sprinkling Streets and Roads.—Sprinkling Car Tracks.—Amount of Water for Sprinkling Streets.—Recording Cost of Street Sweeping.—Cost of Street Sweeping in 25 Cities.—Cost of Street Cleaning, Washington, D. C.—Cost of Sweeping with a "Pick-up" Sweeper.—Estimated Cost of Machine Sweeping.—Estimated Cost of Flushing Streets.—Cost of Street Sweeping, Minneapolis.—Cost of Street Sweeping, Williamsport, Pa.—Cost of Street Sweeping, Albany, N. Y.—Cost of Street Flushing and Sweeping, St. Louis.

SECTION V.—*Stone Masonry*..... 475

Definitions.—Percentage of Mortar in Stone Masonry.—Cost of Laying Masonry.—Estimating the Cost of Stone Dressing.—Data on Stone Sawing.—Cost of Stone Dressing.—Cost of Sandstone Piers for Bridge.—Cost of Cutting Granite for a Dam.—Cost of Cutting Granite, New York City.—Cost of Quarrying, Cutting and Laying Granite.—Cost of Plug Hole Drilling by Hand.—Cost of Pneumatic Plug Drilling.—Cost of Quarrying Granite.—Cost of a Masonry Arch Bridge.—Cost of Centers for a 30-ft. Arch.—Cost of Arch Culverts and Abutments, Erie Canal.—Cost of Lock Masonry, Erie Canal.—Cost of Sweetwater Dam.—Cost of a Granite Dam, Wyoming.—Cost of Masonry, New Croton Dam.—Cost of a Rubble Dam.—Data on Laying Masonry with a Cableway.—Cost of Masonry and Timber Crib Dam.—Cost of Laying Masonry, Dunning's Dam.—Cost of Quarrying and Laying a Limestone Wall.—Cost of Masonry Abutments.—Cost of Laying Bridge Pier Masonry.—Cost of Sodom Dam.—Cost of Dams and Locks, Black Warrior River.—Cost of Rock-Fill Dams.—Cost of Cyclopean Masonry, Cross-References.—Cost of Limestone and Sandstone Slope Walls.—Cost of Granite Slope Wall.—Cost of Laying a Limestone Slope Wall.—Cost of Slope Wall, Upper White River.—Cost of Riprap on River Bank.—Cost of Riprap and Brush Mattress, Cross-References.—Cost of Riprap in a Crib Dam.—Cost of Riprap in Cribs.—Cost of Riprap, Stone, Cross-References.—Cost of Cleaning Masonry with Acid.—Cost of Excavating Masonry.—Cost of Pointing Old Bridge Masonry.—Cost of Lining Tunnel with Masonry.—Cross-References on Masonry.

SECTION VI.—*Concrete and Reinforced Concrete Construction*..... 539

Definitions.—Magnitude of the Subject and General Discussion.—Cost of Manufacturing Cement.—Theory of the Quantity of Cement in Mortar and Concrete.—Size and Weight of Barrels of Cement.—Effect of Size of Sand Grains on Voids.—Tables for Estimating the Cost of Concrete and for Designing Reinforced Concrete Beams and Slabs.—Percentage of Water in Mortar.—Estimating the Cost of Steel in Reinforced Concrete.—Cost of Sand.—Cost of Washing Sand in Tank Washer.—Cost of Washing Sand with a Hose.—Washing Sand with Ejectors.—Cost of Washing Gravel.—Cost of Making Concrete by Hand.—Unloading the Materials from Cars.—Cost of Loading the Materials.—Cost of Transporting the Materials.—Cost of Mixing the Materials by Hand.—Cost of Loading and Hauling Concrete.—Cost of Dumping, Spreading and Ramming.—Example of High Cost of Tamping.—Cost of Rolling and Finishing Concrete Floors.—Cost of Superintendence.—Summary of Costs of Making Concrete by Hand.—Cost of

Mixing Concrete with Machines.—Cost of Mixing with a Gravity Mixer.—Cost of Forms.—Cost of Fortification Work, California.—Cost of Fortification Work.—Cost of Breakwater, Buffalo.—Cost of Locks, Upper White River.—Cost of Locks, Coosa River.—Cost of Locks, Cascade Canal.—Cost of Locks, Illinois and Mississippi Canal.—Labor Cost of Retaining Walls.—Cost of Retaining Walls, Chicago Canal.—Cost of Retaining Wall.—Cost of Retaining Walls, References.—Cost of Filling Pier Cylinders with Concrete.—Cost of Harbor Pier, Wisconsin.—Rubble Concrete Data.—Cost of the Boonton Dam, Cyclopean Masonry.—Some English Data on Rubble Concrete.—Cost of a Rubble Concrete Abutment.—Cost of a Rubble Concrete Dam, Central States.—Cost of Reinforced Concrete Fence Posts.—Cost of Reinforced Concrete Telephone Poles.—Cost of Poles.—Bills of Materials and Cost of Poles.—Cost of Reinforced Concrete Piles for a Building.—Cost of Piles for an Ocean Pier.—Cost of Pile Dike.—Cost of Raymond Piles.—Cost of Rolled Concrete Piles.—Cost of Simplex Piles.—Cost of Concrete Oil Tank.—Cost of Concrete Tanks, References.—Cost of Small Cement Pipes.—Cost of Cement and Concrete Pipes and Sewers, Cross-References.—Cost of a Band Stand.—Cost of Sylvester Wash and Sylvester Mortar.—Cost of Waterproofing with Tar Felt and Asphalt.—Cost of Waterproofing Batteries with Tar and Sand.—Cost of Waterproofing Bridge Floors.—Cost of Waterproofing, Cross-References.—Cost of Removing Efflorescence with Acid.—Cost of Bush-Hammering Concrete.—Cross-References and References on Concrete.

SECTION VII.—Water Works..... 641

Definitions.—Cost of Complete Water Works Systems.—Average Cost of Constructing and Operating Water Works in Massachusetts.—Prices of Cast-Iron Pipe.—Weight of Cast-Iron Pipe.—Lead for Joints.—Items of Cost of Pipe Laying and Materials.—Cost of Loading and Hauling Cast-Iron Pipe.—Trenches.—Cost of Digging a 36-Mile Trench with a Machine.—Trenching in Quicksand, Using a Machine.—Cost of Trenching, Corning, N. Y.—Cost of Trenching, Great Falls, Mont.—Cost of Trenching, Astoria, Ore.—Cost of Trenching, Hilburn, N. Y.—Cost of Pipe Laying, Providence, R. I.—Cost of Laying 187,877 Ft. of Main, Cleveland, O.—Cost of Pipe Laid, Boston.—Comparative Cost of Pipe Laying in New England Cities.—Cost of Pipe Laying and Placing Hydrants, Atlantic City.—Cost of Laying Pipe, Pennsylvania.—Cost of Pipe Laid, Alliance, O.—Cost of Pipe Laid and Service Connections, Porterville, Cal.—An Unusually Expensive Piece of Work.—Cost of a Pipe Line, Ohio.—Cost of Main and Service Pipes Laid in a Southern City.—Cost of Laying Wrought-Iron Pipe, Maryland.—Cost of Taking Up an Old Pipe La. y.—

Cost of Constructing and Laying Cement Lined Pipe, Plymouth, Mass., and Portland, Me.—Cost of Lining Iron Service Pipes with Cement.—Cost of Setting Meters and Laying Service Pipes.—Cost of Meters and Setting, Cleveland, O.—Cost of Setting Meters and Maintenance, Rochester, N. Y.—Cost of Operating and Maintaining Meters, Reading, Pa.—Cost of Placing Hydrants, Chicago.—Cost of Concrete Vaults for Valves.—Cost of Dipping Pipes.—Cost of Cleaning Water Pipes, Pittsburg, Pa.—Cost of Cleaning Pipes, St. John, N. B.—Cost of Cleaning Pipe, Boston.—Cost of Hydrant Maintenance in Winter.—Cost of Thawing Water Pipes by Electricity.—Cost of Stop Cock Box Repairs, Etc.—Cost of Subaqueous Pipe Laying.—Cost of Laying a Submerged Pipe Across Deal Lake, N. J.—Cost of Laying Pipe Across the Susquehanna.—Cost of Laying a Submerged Pipe, New Jersey to Ellis Island.—Cost of Submerged Pipe Laying, Massachusetts.—Cost of Laying Submerged Pipe, Vancouver.—Cost of Laying Pipe Across the Willamette River.—Cost of a Wood Stave Pipe Line, Denver.—Cost of Wood Stave Pipe Line, Astoria, Ore.—Estimated Cost of Wood Stave Pipe.—Cost of Wood Stave Pipe Line, Atlantic City.—Labor on Wood Stave Pipe, Ogden, Utah.—Labor on Wood Stave Pipe, Lynchburg.—Cost of a Reinforced Concrete Conduit.—Cost of a Brick Conduit.—Weight of Steel Stand Pipes.—Cost of a Standpipe, Quincy, Mass.—Cost of Steel Standpipe Encased in Brick.—Brick Casing Around Standpipe.—Cost of a Steel Tank and Tower, Ames, Ia.—Cost of Steel Tank and Tower, Porterville, Cal.—Cost of Steel Tank and Tower, Fairhaven, Mass.—Cost of Steel Tank and Tower, Providence, R. I.—Cost of Scraping and Painting a Stand Pipe.—Weight of Wooden Tank and Steel Tower.—Cost of a Wooden Tank, La Salle, Ill.—Cost of Reinforced Concrete Standpipe, Attleborough, Mass.—Materials in a Reinforced Concrete Standpipe.—Cost of a 12-in. Well, Portersville, Cal.—Relative Cost of Water Works and Filters.—Cost of Filter and Filtering, Ashland, Wis.—Cost of Filter, Berwyn, Pa.—Cost of Filter, Nyack, N. Bridge.

SECTION XIII.—*Steel and Iron Construction*.....1717

Need of More Printed Data.—Cross-References.—Cost of Pneumatic Riveting.—Pneumatic and Hand Riveting.—Cost of Erecting Steel in New York Subway.—Weight of the Eiffel Tower.—Cost of Gas Pipe Hand Railing.—Cost of Erecting a 140-Ft. Steel Stack.—Cost of Iron Work.—Cost of Shop Drawings for Steel Work.—Cost of Sheeting a Foundation Pit with Steel Sheet Piling.—Cost of Driving Steel Sheet Piling for Cut-Off Wall of a Dam.—Cost of Sheet Piling for Cofferdam.—Cost of Driving Steel Sheet Piling.—Cost of Steel Sheet Piling in a Cofferdam and in Calsons.—Cutting Off Steel Sheet Piles with the Electric Arc.—Cost of Driving Steel Sheet Piling.—Cost of Cleaning Steel by Sand Blast and Painting by Compressed Air.

SECTION XIV.—*Engineering and Surveys*.....1745

Cost of Engineering.—Engineering Charges for Services.—Cost of Engineering on City Work.—Cost of Engineering in Reservoir Construction.—Rations for Men

Camping.—Cost of Rations, U. S. Reclamation Service.—Equipment for and Cost of Railroad Surveys.—Cost of 2,000 Miles of Railway Surveys.—Cost of a Railway Survey, Canada.—Cost of Reconnaissance Survey for Railway in Alaska.—Cost of Locating Two Railroad Lines in Michigan and Wisconsin.—Cost of a Railroad Re-Survey, Canada.—Cost of Re-Survey of Chicago & West Michigan Ry.—Cost of Re-Survey of Detroit, Grand Rapids & Northern Ry.—Cost of Railway Surveys.—Cost of Transit Lines in Heavy Timber.—Cost of Topographic Survey for 160-Acre Park.—Cost of Topographic Survey of St. Louis.—Cost of Stadia Survey, Baltimore.—Cost of Topographic Survey, Westchester Co., N. Y.—Cost of Topographic Survey Near Baltimore.—Cost of Three Stadia Topographic Surveys.—Cost of Surveys, Erie Canal.—Cost of U. S. Deep Waterway Survey, New York.—Cost of Government Topographic Surveys.—Cost of Triangulation and Plane Table Surveys.—Cost of Topographical Survey, Texas.—Cost of Two Small Surveying Jobs.—Cost of Level Survey for a Drainage Plan.—Cost of Sounding Through Ice.

SECTION XV.—Miscellaneous Cost Data.....1779

Supplies and Plant Prices of Materials.—Cost of Fences.—Cost of Barbed Wire Fences.—Cost of a Wire Fence.—Cost of Digging Post Holes for a Fence.—Cost of Digging Post and Pole Holes.—Cost of Digging 600 Trolley Pole Holes.—Weight of Ashes, Garbage, Etc.—Cost of Garbage Reduction and Collection at Cleveland, O.—Cost of Garbage Disposal, Milwaukee, Wis.—Garbage Incineration, San Francisco.—Cost of Removing Ashes.—Cost of Tile Drains.—Weight of Drain Tile.—Prices of Tile Drains in Place.—Cost of Digging a Trench and Laying Tile Drains.—Cost of Farm Drainage.—Cost of Tile Trenching with a Machine.—Cost of Laying Small Gas Mains on Six Jobs.—Cost of Laying Wrought Iron, Screw Joint Pipe for Compressed Air Main.—Cost of Maintaining Teams.—Cost of Horse Maintenance.—Cost of Maintaining Horses, New York City.—Feed of Street Car Horses.—Cost of Maintaining Farm Horses and Raising Hay and Oats in Minnesota.—Cost of Maintaining Mules.—Shipping Contractors' Horses in Cars.—Hauling Heavy Machinery in Wagons.—Handling Teams with a Jerk Line.—Cost of Plowing Farm Lands with a Steam Traction Engine.—Cost of Traction Engine Haulage of Ore.—Cost of Handling and Screening Cinders.—Size, Weight and Price of Expanded Metal.—Price of Mineral Wool.—Cost of Sodding.—A Device for Cutting Soil for Sodding.—Painting Data.—Cost of Painting a Tin Roof.—Unloading Coal from Cars with a Clamshell.—Cost of a 28-Mile Telegraph Line.—Cost of a Telephone Line.—Cost of Two Telephone Lines.—Life of Telephone Line Equipment.—Cost of Laying Electric Con-

duits.—Cost of Vitrified Conduits, Memphis.—Cost of Brick Manholes for Electric Conduits.—Methods and Cost of Laying Vitrified Conduits for Electric Wires.—Cost of Pole Lines, Vitrified Conduits, Manholes, Etc.—Labor Cost of an Electric Transmission Line.—Cost of a Transmission Line for Interurban Electric Railways.—Estimating the Horsepower of Contractors' Engines and Boilers.—Cost of Cutting Cord Wood.

HANDBOOK OF COST DATA.

INTRODUCTION.

John Stuart Mill has said: "Without any formal instruction, the language in which we grow up teaches us all the common philosophy of the age."

If it is even partially true that general knowledge is affected by words and expressions in common use, it is certainly undeniable that formal definitions of words have a much greater effect upon the scope of mental vision. When the formal definition is of a word that denotes a profession, the far-reaching consequence can hardly be estimated. No definition of any profession has had wider circulation and more general acceptance than the old one formulated by Tredgold and adopted in its infancy by the Institution of Civil Engineers:

"Engineering is the art of directing the great sources of power in nature for the use and convenience of man."

Note the entire absence of any reference to economics in this definition. Engineering, when Tredgold lived, was in the stage of development when the common problem before an engineer was not whether a thing could be done economically but whether it could be done at all. Then followed the reign of the mathematicians who took up engineering, just as in previous years mathematicians had seized upon astronomy as a delightful science in which to exercise their talents. But among mathematicians there has always been a liking for the ancient toast: "Here's to pure mathematics. May it never be of any use to anybody." So it was naturally to be expected that anything so "commercial" as saving money should not have appealed very strongly to the mathematicians who had taken up engineering. Nor did it. Nor has there been an entire escape to this day from the bondage of that early type of engineering. Tredgold's definition really fails to define, or limit, the word engineering. Under his definition any man who directs any of the great forces of nature for the use of men is an engineer. The farmer who utilizes that enormous force—the sun's heat—for the "use and convenience of man," is an engineer. So, too, is the sailor who directs that other vast force, the wind, to the driving of his ship. In fact, there is no limit to the classes of men who fall within the literal wording of this definition. It is, therefore, a very unsatisfactory definition because of its vagueness. However, I object to it not so much upon the ground that it includes too much as upon the ground that it fails to include what it should, namely the fundamental function of the modern engineer, which is to solve problems in economic production.

I recall with what keen interest I first read that now historic work, Wellington's "Economic Theory of the Location of Railways." I was particularly struck with this opening paragraph:

"It would be well if engineering were less generally thought of, and even defined, as the art of constructing. In a certain important sense it is rather the art of not constructing; or, to define it rudely but not inaptly, it is the art of doing that well with one dollar, which any bungler can do with two after a fashion."

Wellington made no attempt to give a complete definition of engineering, but he certainly was among the first, if not the first, to indicate the inherent weakness of such definitions as that of Tredgold. Wellington has it to his lasting credit that he made a valiant effort to reduce railway location to an economic science. That he made many errors, or that he was not always even logical, detracts little from his eminent position as one of the greatest teachers of what engineering really is.

Engineering is the conscious application of science to the problems of economic production.

Under this definition, which may ultimately be regarded as too broad, I aim to include that part of engineering which relates to the scientific management of men, and the scientific development of methods of construction and operation, as well as the design of the most economic structures and machines for a given service. The word art does appear in the definition, for it is obvious that in the application of scientific principles in the solution of any problem, what may be termed "art" must be exercised if the greatest success is to follow. Natural aptitude, practice and experience are the qualifications of every man who is a real artist in the execution of a task. These are the qualities that cannot be imparted by teaching.

Since engineering in the modern sense of the term consists in solving problems in economic construction and operation, it should be apparent to all that cost data are of primary importance to every engineer. For, just as data on the resistance of materials to stress are essential in economizing the materials in a bridge, a building, or a machine, so data as to unit costs of construction, operation and maintenance are vitally valuable to every engineer who attempts to be an engineer in the modern meaning of the term.

To my great surprise, the first edition of this Handbook of Cost Data was scarcely off the press before editorials and articles began to appear in certain engineering periodicals belittling the value of cost data. I had taken particular care, as I had thought, in pointing out the difference between the price of anything and its actual cost. Yet it was said by writers that prices fluctuated so rapidly that cost records are of no particular value except for very short periods of time. Lest this confusion of terms shall continue to mislead, I purpose briefly indicating again their meaning.

The price of any article is the money paid for it by a consumer. It is the cost to the consumer, and in that sense of the word I use the term cost occasionally in this book, but never in such a way as to cause confusion, the meaning being always obvious by the context.

The cost of any article is money paid by the producer for materials, supplies, labor, etc., necessary in its production. His profit is the difference between this cost and the price he receives.

Clearly, then, if we give the number of hours or days of labor of a stated class required to produce a unit of product, we have given its cost in terms that may be of permanent value, so long as the same methods of doing the work remain in vogue. In brief, we have given the cost in terms of the day's output of a man, and this is by no means a quantity subject to erratic fluctuations. Indeed, under equally good management such costs are often astonishingly stable. If anyone doubts this statement, I ask him to compare the data in my little book "The Economics of Road Construction," written in 1900, with corresponding data in Aitken's "Road Making and Maintenance," published a few weeks after I had turned over my manuscript to my publishers. Aitken wrote of English methods and cost of building macadam roads. He used American rock drills and English steam rollers. I used machines and tools almost identical, and our respective unit costs were, on most items, nearly identical when reduced to the same unit rates of wages.

It is the veriest nonsense to attribute to cost data an 'ephemeral or purely local value, because prices vary with supply and demand, or because local conditions differ more or less. Prices have nothing to do with the matter at all in making proper comparisons of cost data, since, if quantities of materials and quantities of labor are stated, the substitution of standard prices for materials and of standard wages for labor is a mere matter of common sense and the multiplication table.

Fallacies, however, die with cat-like protraction. Hence, when the first published objections to the real and general value of published cost data were seemingly killed, I found them struggling to life again. In a recent paper before the American Society of Civil Engineers it was urged that, while cost data may be valuable they are of no great value except to the man who gathered the data! This same fallacy has also been repeated in two engineering journals, both editorially and in contributed articles.

Were it not for the sources of these errors I should ignore them. But they seem to merit at least a passing notice.

Cost data differ from other engineering data in no essential respect, except, perhaps, in this: Workmen who are underpaid, or poorly managed, or arrogant because of a false feeling of independence, may not do a full day's work. When this is so, unit costs are necessarily high if measured in terms of the man-day. This condition, however, can be recorded, and, in fact, it records itself if we have other data for comparison.

Cost data can be so reduced to items and accompanied by statements of conditions as to be of as much value to engineers and contractors as any other kind of data. Data of strengths, for example, are very misleading if unaccompanied by descriptions of the size of test pieces, chemical composition, and many other factors, which are entirely analogous to the "local conditions" that cause variations in cost data. By curious coincidence, one of the engineers who has most severely criticised cost data is the author of a 250-page book giving nothing but records of strength and elasticity tests of Portland cement and concrete. If cost data were subject to

a tenth of the variation found in these cement strengths, well might we despair of reducing the subject of cost estimating to a science.

This last expression leads me to the real heart of the subject of this book, and the heart is not cost estimating—at least it is not that *per se*. Important as the matter of estimating costs often is, the overshadowing value of cost data as a guide in reducing costs will be apparent to every engineer, contractor or manufacturer who has been long engaged as a producer of things for sale.

Comparison of unit costs is the only scientific criterion by which to judge the economic merit of a structure, a machine, or a method of doing work.

This fact is so self-evident that its meaning needs but to be understood to find full acceptance by everyone of open mind and unclouded brain. Yet, failure to formulate this law has led to some of the most astounding methods of designing and of selecting engineering structures. For example, in nearly every American treatise on highway construction will be found a method which the highway engineer is supposed to follow in selecting the type of pavement for a given street. The method consists in assigning percentages to each of the qualities that pavement has, as follows:

	Per cent.
Low first cost.....	15
Low cost of maintenance.....	20
Ease of traction.....	10
Good foothold	5
Ease of cleaning.....	10
Noiseless	10
Healthfulness	10
Free from mud and dust.....	10
Comfortable to use.....	5
Non-absorbent of heat.....	5
Total	100

If a pavement possesses any one of these qualities to perfection, the full percentage assigned to each quality is credited to that pavement. The pavement showing the highest total percentage is the one to be selected. This looks somewhat scientific, with its tabulation of ratios, but it is not even scientific guesswork. As well choose a suit of clothes by assigning 10% to the buttons, 50% to the cloth and 40% to the style. Pseudo-science of this sort would never have gotten into the pages of engineering textbooks had there been a clear and complete definition of engineering in the minds of the authors. I need not stop to point out the scientific method of designing or selecting a pavement, for that will follow as a corollary to the criterion for economic design, given later.

I wish here to emphasize the fact that no paper read before an engineering society, nor any article printed in an engineering periodical on the design of a machine or structure, is ideal in its character unless it is accompanied by cost data. I would not be understood, however, as saying that the absence of cost data makes an article of this sort worthless. Far from it. But the absence of cost data weakens the article, for, without the accurate criterion that

cost data—and cost data only—furnish a precise judgment as to the economic merit of the machine or structure is impossible.

The same holds true of a method of doing work, and that is why I have chosen to link the words *methods and cost* in the subtitles of several of my books on construction.

Often a cost is so nearly a function of the amounts of material required in a structure or machine that the dollar's mark need not appear at all—simply the quantities of each kind of material per unit of product. This is particularly true of steel bridges. Perhaps this fact accounts, in a measure, for the indifference of some bridge engineers to the importance of cost data. They fail to see that in other lines of engineering the quantity of materials is not always a function of the cost. But even in bridge work it is fatal to true economy to have eyes only for the amount of materials required for the structure. A study of the section on bridgework in this book will make evident this fact.

In the operation of plants of given capacity and of stated class, cost data are invaluable as a criterion of the efficiency of machines, of men and of management. Unfortunately, most writers on this branch of cost data have hitherto recorded only the dollars and cents cost of the various items of operating expense. We often find, for example, that the item of fuel has cost so and so many dollars per year, or per horsepower-year, without a word as to the number of tons of fuel and the price per ton. We read that the wages of operation totaled so and so, without finding a detailed statement of the organization of the operating crew and the rates of wages paid to each class of men. We are told that repairs cost so and so many dollars per year, but the first cost of the plant is omitted, so that we are unable to reduce the repairs to a percentage of the first cost; nor is the age of the plant stated, so that, even if its first cost were given, we should be in doubt as to whether the plant had been long enough in use to reach a stage of average repairs.

All such omissions, however, are not a fair indictment of cost data. A just criticism of imperfect cost data, or of imperfect records of the conditions to which they apply, is quite a different thing from an attempt to belittle the value of all cost data "except to the man who gathered them." Were it literally true that cost data are of worth only to the man who has seen the local conditions, we should, indeed, be in a sorry state. The civil engineer engaged in locating a railway, having never personally gathered any railway operating costs, would be compelled to ignore all such cost data in solving the various problems of location.

Where, indeed, will this nonsense lead us, if we will be lead by it? Obviously to a point where no engineer will dare use any cost data at all, except his own meager pickings from his own little crab-apple tree of experience.

The great and steadily greater growing efficiency of engineers is due to their use of all kinds of data—cost data included—gathered by all kinds of engineers.

I expect to live to see the day when a knowledge of cost data and how to use them will be generally regarded by engineers as of

greater importance even than a similar knowledge of the physical properties of materials.

Finally, in this foreword, I would impress upon young engineers the importance of examining the definitions of all terms with care. I have indicated how a confusion as to the words price and cost has often resulted in speaking of costs as not being stable when what was meant was the instability of prices. I have indicated how an ancient definition of the word engineering may have been a factor in leading many engineering educators to follow the old precedent too closely for the good of the students who, upon graduation, must change their conceptions of what are the most common and the most important engineering problems.

In the following pages will be found a striking illustration of the errors that some engineers have made through confusing the words depreciation and repairs.

I commend to all engineers the careful study of Mill's "System of Logic," and particularly his chapters on Definition and on Fallacies of Confusion.

SECTION I

PRINCIPLES OF ENGINEERING, ECONOMICS AND COST KEEPING.

Definitions.—Not only for the benefit of younger men and of foreign engineers does it seem wise to give the following definitions, but because there is not at present an entire uniformity among American engineers as regards the meaning of some of the terms.

Amount.—The principal plus accumulated interest.

Amortisation.—The extinction of a debt by means of a sinking fund, or the provision for the redemption of an investment in a plant, a mine, or the like, by means of a sinking fund.

Betterment.—An improvement. In railway parlance, any expenditure for "addition and improvement."

Bid.—To submit a contract price; the bidding price being the tender.

Book Value.—The value of a plant as recorded in the accounting books of a company. Often it represents the price paid for the plant and the franchise under which it operates. Often it is the estimated depreciated value.

Bonus.—A payment to a workman in addition to his hourly, daily or weekly wage. The bonus system is a modified piece rate system by which a workman receives a stipulated price (= bonus) for each unit of work done in excess of a stipulated minimum, in addition to his regular wage.

Capitalise.—To divide an annual operating or maintenance expense by a rate of interest. The quotient thus obtained is called the capitalised cost of the annual expense.

Contingencies.—Unforeseen expenses.

Cost.—The actual cost of materials, supplies, labor, etc., required to produce an article or to perform a service. Also frequently used to denote the price that a purchaser has paid.

Cost of Reproduction.—The present cost of a plant, or plant unit, regarded as reproduced new at present prices.

Data.—Facts, and particularly those that can be numerically expressed. The word is the plural of datum, but so many writers use the word data with a singular verb that it seems likely to follow the precedent of such words as news. In Shakespeare's time,

news was used only in the plural; now it is always singular.

Demurrage.—The amount paid a railway company for holding a car beyond a certain time.

Depreciation.—Decrease in value. It is preferable not to use the word to denote "repairs and renewals," but to use "maintenance" for that purpose. Depreciation is best used only to denote annual expense for the entire renewal of a plant unit. It will then be either the amount annually placed in a sinking fund, or the amount paid out of current income for plant renewals, renewals, in the latter case, being regarded merely as repairs on a larger scale. Three formulas for depreciation are given in the following pages: (1) The straight line formula; (2) Sinking fund formula; (3) Unit cost of production formula.

Equipment.—In railway parlance, rolling stock, including locomotives and cars. Unfortunately the term has been latterly used to include the power stations and electrical plant of electric railways. It will be well to discontinue the use of equipment in any sense but as relating to rolling stock.

Fixed Charges.—Often used to denote only the interest charges on the funded debt of plant, but more often used to include all expenses that go on whether a plant is in operation or not.

Funded Debt.—The bonds of a railway.

Going Concern Value.—The amount of money expended in building up a business, or the measure of increased value possessed by an old business over a similar business just started with a new plant.

Maintenance Expense.—The annual expense for repairs and entire renewals of plant units.

Materials.—The substances actually entering the construction of a machine or structure, as distinguished from supplies. This distinction is not always made, but is desirable.

Obsolescence.—The state of going out of use through becoming obsolete.

Operating Expense.—In railway parlance this includes the expense of operating and maintaining a railway plant. The operating ratio is the ratio of operating expense to gross earnings. In manufacturing and contracting parlance, operating expense often does not include maintenance, which is classed as a distinct item, and includes repairs and renewals.

Original Cost.—The actual original cost of a plant, including additions and improvements, but not including profits resulting from the sale of the completed plant.

Overhead Charges.—Generally used to include only office expenses and general miscellaneous expenses, the latter being so general that they can not be charged either against the office or field or shop, but are incurred in the maintenance of the business in general.

Piece Rate.—A rate paid to a workman for each unit, or piece, of work performed. When an increasing piece rate is paid as the number of units of output increases, it is called a *differential piece rate*.

Plant.—The physical property used in production, including machinery, land, etc.

Present Value.—Depreciated value.

Price.—The market price, as distinguished from the actual cost to produce a structure, machine, or the like.

Principal.—The original sum upon which interest is calculated.

Reciprocal.—The reciprocal of a number is 1 divided by that number. The reciprocal of 20 is $1/20$, or 0.05, or 5%.

Scrap Value.—The price that is realized from the sale of a depreciated machine or structure.

Shop Repairs.—The repairs that a machine receives in a shop, as distinguished from repairs received in the field.

Sinking Fund.—A fund established for the ultimate payment of a debt, or for the redemption of an investment in a plant, mine, etc. An annual deposit is ordinarily made in the fund, and the fund increases by these deposits and by compound interest.

Supplies.—All items of material necessary to carry on work, but which are rapidly destroyed in the process of production; e. g., coal, rope, hose, etc. See *Materials*, above defined.

Tender.—To bid.

Unbalanced Bid.—A bid in which certain unit prices are above a fair price and other unit prices are below a fair price.

Unit Cost.—The total cost of producing a unit, such as a cubic yard of concrete.

Unit Interest Cost.—The total annual interest on a plant investment divided by the total number of units of product. A plant unit may be a single machine, or a single structure.

Value.—The worth of a thing. This may be its market price, or it may be a sum arrived at by estimating depreciated value, or it may be a sum determined by capitalizing annual net earnings, or it may be a sum determined by capitalizing annual saving in operating or maintenance expense. See *Book Value*, above.

Compound Interest Tables.—These are ordinarily given in two forms, as in Tables I and II.

Let A = amount, or accumulation of \$1 and interest during n years.
 r = rate of interest, payments made at the end of each year.
 n = number of years.

Then (1) $A = (1 + r)^n$.

Table I is calculated by formula (1). If the principal is \$20, simply multiply the amount found in Table I by 20; and in like manner for any other principal. It is convenient to bear in mind that money at compound interest doubles itself in approximately the number of years obtained by dividing 72 by the rate of interest. This is not strictly accurate, as may be seen from Table I, but, for the rough and ready estimates that an engineer is often called upon to make, it will generally suffice.

Table I is, for many engineering purposes, less convenient than Table II, which is also a compound interest table. The amounts given in Table II are the reciprocals of the corresponding amounts in Table I. Table II is useful in determining the *present value or present justifiable expenditure to secure a return of \$1 at the end of any number of years.*

To illustrate the use of Table II, suppose it to be probable that the traffic of a projected change of railway line will be double in ten years what it is at present.

Suppose that present operating expenses can be reduced by an improved location of the line, and that the capitalized value of the saving in present operating expenses is \$1. Then there is certainly economic warrant for spending that \$1, but how much may be now spent to save the other \$1 in operating expenses which will be effected by this improvement when traffic shall have doubled 10 years hence?

Table II gives the answer; for if money can be borrowed at 5%, the table shows that \$0.614 may be spent now to secure a betterment which will yield a capitalized value of \$1 in reduced operating expenses 10 years hence.

Therefore the total present justified expenditure becomes \$1.614, of which \$1 is the capitalized saving in present operating expense and \$0.614 the capitalized saving in future operating expense when the traffic shall have doubled.

As Wellington points out, this is the maximum justifiable expenditure to effect a future saving in operating expense; for, unless there is assurance that earnings will be sufficient to pay the interest upon the increased obligations, danger exists of financial embarrassment which may result disastrously to the railway owners.

TABLE I.—COMPOUND INTEREST TABLE.
Amount of \$1 Placed at Compound Interest for a Term of Years.

Years.	3 per cent.	3½ per cent.	4 per cent.	5 per cent.	6 per cent.	8 per cent.	10 per cent.

Sinking Fund Tables.—Table III is a sinking fund table, or annuity table, that gives the deposit that must be annually placed in a fund drawing compound interest to amount to \$1 at the end of a given term of years.

d = annuity, or sum deposited at the end of each year, which will amount to \$1 in n years.

r = rate of interest, interest payments being made at the end of each year.

n = number of years.

Then

$$d = \frac{r}{(1+r)^n - 1}$$

Table III gives the values for d , for any rate of interest (r) and any term of years (n).

If it is desired to redeem an investment of, say, \$1,200, at the end of 25 years, interest being 4%, Table III gives $d = 0.02401$, which would redeem \$1. Hence $0.02401 \times \$1,200 = \28.812 , which is the annual deposit in the sinking fund necessary to redeem the \$1,200.

Table IV is also a sinking fund table, its values being the reciprocals of the corresponding values in Table III. Table IV gives the accumulation of annual deposits of \$1 at the end of each year and the interest on the same compounded annually. The use of this table involves the operation of division, which is not ordinarily so rapid as the operation of multiplication. To illustrate, let us assume the same problem as before: It is desired to ascertain the annual deposit in a sinking fund necessary to redeem \$1,200 at the end of 25 years, interest being 4%. Table IV gives the accumulation of \$1 in 25 years at 4% as being \$41.66. Hence $\$1,200 \div 41.66 = \28.805 . This is not quite the same as the result secured with Table III, due to the fact that Table IV is not carried out to as many decimal places.

Present Worth of Annuity.—Table V is useful in determining the justifiable present expenditure to save \$1 per year for various terms of years. In other words, Table V gives the capital sum that will return \$1 per year in interest during the term of years and will also return an additional sum in interest each year sufficient to extinguish the principal at the end of a term of years if placed at compound interest.

The present worth, W , of an annuity is given by the formula

$$W = \frac{(1+r)^n - 1}{(1+r)^n r}$$

Table V was calculated by this formula.

References and Cross-References.—At the end of the Waterworks Section of this book will be found an abstract of an excellent article by Mr. Leonard Metcalf on the appraisal of waterworks, wherein are given various sinking fund formulas and curves.

For the deduction of the formulas given in the preceding pages, consult any higher algebra, or Frye's "Civil Engineer's Pocketbook."

TABLE IV.—SINKING FUND.

(The amount (or accumulation) when \$1 is deposited annually in a fund whose interest is compounded.)

At End of Year.	—Rate of Interest, Per Cent.—

Identity of Machine and Engineering Structure.—An engineering structure that performs a useful service is, in essence, a machine. A railway is a machine for manufacturing transportation. A street or road is part of a similar machine, the vehicles being the other part. Buildings are part of a manufacturing plant. Even when built merely to rent, they are machines for producing rentable floor area.

In solving problems in engineering economics, the young engineer will be greatly aided by keeping in mind this identity of what is commonly called a "machine" and what is commonly called a "structure."

Problem 1. Which of Two New Machines (or Structures) to Select.—This problem consists in determining which machine yields the desired number of units of product at the lowest cost.

Let

N = number of units produced annually by the 1st machine.

n = number of units produced annually by the 2d machine.

C = first cost of the 1st machine.

c = first cost of the 2d machine.

D = per cent of annual renewals, or annuity in sinking fund for 1st machine.

d = per cent of annual renewals, or annuity in sinking fund, for 2d machine.

R = per cent of annual repairs for 1st machine.

r = per cent of annual repairs for 2d machine.

I = per cent of annual interest on capital.

O = annual operating expense of 1st machine.

o = annual operating expense of 2d machine.

U = unit cost of production with 1st machine.

u = unit cost of production with 2d machine.

Then

$$(1) \quad U = \frac{O + RC + DC + IC}{N}$$

$$(2) \quad u = \frac{o + rc + dc + Ic}{n}$$

Since U must be less than u , to warrant the selection of the 1st machine in preference to the second, we have

$$(3) \quad \frac{O + RC + DC + IC}{N} < \frac{o + rc + dc + Ic}{n}$$

Ordinarily, the number of units to be produced by each of the two machines is equal, or $N = n$. Then we have:

$$(4) \quad O + RC + DC + IC < o + rc + dc + Ic$$

Expressed in words we have this criterion:

Select the machine that shows the least sum of these four items of cost: (1) annual operating expense, (2) average annual repairs, (3) average annual renewals, and (4) annual interest on the investment.

Note carefully that there are two different methods of determining D , the percentage of first cost allowed for annual renewals. By the

method in vogue on railways, D is the reciprocal of the life of a machine, hence for a locomotive having a life of 25 years, D is 4%. By the method often used for smaller plants, D is the annuity placed in a sinking fund to redeem the investment in a machine at the end of its life. In the first case, renewals are treated like current expenses for repairs, and this is justified where a large number of plant units of different ages are in operation.

Formula (4) can be put in another form, thus:

$$(5) \quad I(O - c) < (o + rc + dc) - (O + RO + DO)$$

A still more common form is this:

$$(6) \quad O - c < \frac{(o + rc + dc) - (O + RO + DO)}{I}$$

Between two new machines of equal capacity, the higher first cost of one is economically justified when its excess cost is less than the capitalized saving in annual operating and maintenance expenses due to its use.

For the benefit of young engineers the meaning of the word "capitalize" should be explained.

To capitalize an annual expense consists in dividing it by the rate of interest at which money can be borrowed.

Thus, if a man is required to perform a certain class of work at an annual expense of \$500, and if the rate of interest is 5%, the capitalized cost of this annual expense is $\$500 \div 5\% = \$10,000$.

Reverting to the rule following formula (6) we see that it is the one which Wellington has applied to the various problems of railway location in his "Economic Theory of Railway Location." I prefer, however, to use the criterion as given in formula (6), because sight is not then lost of the fact that maintenance expenses are a function of the first cost of the machine under consideration. That this is an important improvement over Wellington's criterion will be seen when one examines Wellington's data on the maintenance of locomotives, as well as other maintenance data in his book. There the maintenance is recorded not as a percentage of the first cost of the locomotive but in the train-mile as the unit. Yet Wellington knew that the first cost was a factor in maintenance cost, for he says (p. 144 of his book): "Half the total cost of engine repairs varies as the weight, and half is independent thereof." Incidentally, I may say that he was entirely wrong in this conclusion, for the cost of annual repairs varies almost directly as the weight of a locomotive. Again he speaks (p. 148) of the fact that passenger engines cost about 20% less for repairs than freight engines, without recognizing that the difference in weight and first cost was what accounted for this difference in repairs.

Formula (3) or (6) should be invariably used not only by engineers who are selecting or designing machines for a given purpose, but by engineers who are designing structures of all kinds. I have already stated that engineering structures should be regarded either as machines or as parts of machines. At first sight it may appear that some structures are not at all like machines in that they seemingly have no operating expense (O).

In the case of a country road, for example, the item of operating expense (O) may appear to be non-existent; although, in fact, a little thought makes it clear that the owners of the horses and wagons, motor cars, etc., pay this operating expense, which should be as certainly considered by the engineer who is locating and designing a road or street as it would be considered if he were locating and designing a railway.

In certain classes of work, serious error will occur if there is failure to give proper consideration to N and n in formula (3). This is strikingly seen in the ordinary designs of country highways, where failure to determine the number of ton-miles ($=N$) to be hauled annually leads to the most glaring blunders in designing the road.

In selecting an engine for a given purpose, the same error is frequent. The engineer whose mind is fixed upon economy of fuel, for example, is very apt to choose a type of engine so expensive in first cost that the unit interest $\frac{I}{N}$ is so greatly increased as to exceed greatly the unit fuel saving.

A blunder often made by contractors is the selection of a machine that is too large for the work in hand. Not only does too large a machine increase the unit interest and unit maintenance, but it often increases the unit operating expense $\frac{O}{N}$, due to the fact that its size makes it expensive to move or shift from place to place. This is particularly true of large steam shovels used on small excavations.

The item of operating expense (O), as the term is here used, includes supervision, taxes, labor (except for maintenance), fuel and other supplies, materials, etc.

Some statisticians insist that taxes should not be regarded as an operating expense, because unit taxes tend to increase while other unit operating items tend to decrease as the plant grows in size. Even if this were true, I fail to see sufficient reason for segregating taxes with fixed charges. But I deny the truth of the statement that unit taxes must necessarily increase. If corporations have lied to tax assessors, then unit taxes do eventually increase when the lies are found out, and that is precisely what has caused most of the increase in unit taxes in recent years. The subject, however, is not one of sufficient importance in this connection to merit more than passing notice.

The item of annual repairs (RC) is commonly underestimated, and is grossly underestimated in the majority of instances that I have seen in print.

The cost of annual repairs is not a constant for each year, but increases, at least for a time, as the plant grows older. Hence, if estimates of maintenance are based upon the maintenance costs during the earlier part of the life of a machine (or structure), serious errors result. This subject will receive consideration at greater length in subsequent pages.

The item of renewals (DO) relates to entire renewals of plant

units, such as the entire renewal of a locomotive. The rate, D , may be the reciprocal of the life of the plant unit. Thus if the life is 20 years, the annual rate of renewal (D) is 5%. Many engineers prefer to use the annuity deposited in a sinking fund, instead of this rate of renewal, D . In such a case, use Table III. For example, a life of 20 years, with interest at 5%, would require an annual deposit of \$0.0372 to redeem \$1, which is equivalent to 3.72% rate to be used instead of the 5% obtained by the straight line formula.

I prefer, however, not to use the sinking fund method in cases where a large number of similar plant units are under consideration, as in the case of a railway. The reasons for this preference will be given subsequently.

Problem II. When to Retire An Old Machine in Favor of An Improved or Larger One.—Like Problem I, this problem involves the determination of unit costs of production. We shall, therefore, use the same symbols as on page 17, with the addition of

c_1 = salvage value of the old machine.

Then the unit cost of production with the new machine will be

$$(7) \quad U = \frac{O + RC + DC + I(C - c_1)}{N}$$

and

$$(8) \quad u = \frac{o + rc + dc + Ic}{n}$$

Since U must be less than u to warrant the purchase of the new machine, we have

$$(9) \quad \frac{O + RC + DC + I(C - c_1)}{N} < \frac{o + rc + dc + Ic}{n}$$

Ordinarily the new machine is expected merely to turn out as many units of product as the old machine is already delivering, in which case $N = n$, and we have

$$(10) \quad O + RC + DC + I(C - c_1) < o + rc + dc + Ic$$

Whence

$$(11) \quad O - (o + c_1) < \frac{(O + RC + DC) - (o + rc + dc)}{I}$$

In words this means: *The purchase of an improved machine of the same capacity as the old is economically justified when its excess first cost over the sum of the first cost and salvage value of the old machine is less than the capitalized saving in annual operating expense and maintenance effected by the new machine.*

If $c_1 = o$, formula (11) becomes identical with formula (6), because the old machine has then perished, and we are comparing two entirely new machines. If the old machine can be disposed of for its full first cost, then $c_1 = c$, and formula (11) becomes:

$$(12) \quad O - c < \frac{(O + RC + DC) - (o + rc + dc)}{I}$$

Expressed in words this is: *If an old machine has a salvage value equal to its full first cost, the purchase of an improved machine is justified if the excess cost of the new machine over double the first*

cost of the old machine is greater than the capitalised saving in annual operating expense and maintenance effected by the new machine.

This is a condition rarely existing, but it is well worth remembering as indicating an extreme case which may be approached more or less closely at times.

The Life of a Machine or Structure and the Growth of Annual Repairs.—Probably no subject in engineering economics has been enveloped in a greater haze of contradictory opinions than this. Many eminent engineers maintain the doctrine that the curve of annual maintenance resembles some sinking fund accumulation curve—a doctrine that rests wholly on speculation and has never had a single curve of actual maintenance cost adduced in its support, so far as I have been able to discover. Actual curves of machine repairs of individual machines are ordinarily not regular curves at all, but are saw-toothed lines, usually of great irregularity.

As fairly typical of a large class of machines, I will take a railway freight car, whose wheels, axles, brasses, brakes, draw-bars, trusses, paint, etc., constitute the separate parts subject to the wear and tear due to use and exposure to the elements. The life of each of these parts is the average life, and the cost of renewal of the part is the cost ascertained by deducting the scrap value from the original value of the part in place. This is not strictly correct, for the labor of renewing a part is usually greater than the labor originally involved in assembling the parts. For our present purpose, however, this difference is not material.

Table VI gives the data for a small box car of about 30,000 lbs. capacity, and will serve our purpose if we bear in mind that it slightly underestimates the actual cost of renewals of parts, for the reason above given.

TABLE VI.—BOX CAR REPAIRS.

Track: Item.	First cost.	Scrap value.	Net cost repairs.	Life, years.	Average annual repairs.
(1) Wheels	\$ 90	\$ 35	\$ 55	4	\$13.75
(2) Axles	45	15	30	3	9.75
(3) Brasses	10	4	6	3	2.00
(4) Frame	95	25	70	35	2.00
Total truck.....	\$240	\$ 79	\$161	..	\$21.50
Box:					
(5) Brakes	\$ 10	\$ 3	\$ 7	6	\$ 1.33
(6) Draw-bars ...	29	6	23	6	3.83
(7) Frame	60	10	50	15	3.33
(8) Roof	29	4	25	8	3.12
(9) Floor	12	1	11	10	1.10
(10) Sides	44	2	42	20	2.10
(11) Painting	8	0	8	7	1.14
(12) Trimmings ...	20	3	17	20	0.85
(13) Trusses	6	3	3	20	0.15
Total box	\$218	\$ 31	\$187	..	\$16.95
Grand total.....	\$458	\$110	\$348	..	\$38.45

There are 13 parts given in Table VI. If we add their lives, as given in the last column, and divide by 13, we get 12.2 years, which might be called the "unweighted" average life. It is obviously not the true average.

If we divide the total average annual repairs, \$22.45, into the total net cost of repairs, \$448, we get 20.0, which has been called the "average life of the car," but this, too, is deceptive. Nor would it be more correct to divide the total first cost, \$458, by \$22.45, for the quotient, 20.4, is not the average life. The fact is, that the average life of a car, taken as a whole, bears no necessary relation to the average life of any or all its parts, as will be explained more fully later on. Average annual repairs, such as the \$22.45 given in Table VI, is an item involving credits for scrap value, thus making it impossible to derive the average life of the parts, using life in any true sense of the word. The average life of a machine is not deducible from its average annual repairs.

Referring to Table VI, we see that the life of the frame of the truck is 35 years. Therefore, before the frame requires renewal, nearly all the other parts will have been renewed several times. If the frame were assigned a life of 40 years, there would not be a single part that had not required at least two lives to equal the life of the frame. But the life of the longest lived part does not itself determine the life of the machine, for, as in this case of the car, a new truck frame might be provided at the end of 35 years. Then the car would be prepared to go on living another 35 years.

We see, then, that the average life of a machine taken as a whole may bear no necessary relation to the average life of any of its parts, even of its longest lived part. The fact is that the actual life of most machines is determined by no self-contained elements of destruction, but by "improvements in the art" or by increase in the service required of the machine, necessitating, in the first case, an improved machine, and, in the second case, a larger machine. The death of most machines is, therefore, caused by obsolescence—the machine having outlived its economic usefulness, though still capable of rendering service. In America, the actual average life of railway cars and locomotives has not much exceeded 20 to 25 years. In Europe and England, cars and locomotives more than half a century old are in common use yet. On the whole Northern Pacific Railway (U. S.) the oldest locomotive is only 33 years old. Such is the difference in obsolescence in America and Europe. In a growing community it is obvious that obsolescence of certain classes of machines will be much more rapid than in a community whose growth is slow. Thus, a pump may economically serve a water-works in a growing community not longer than ten years, while the same pump might economically serve a non-growing community for thirty years, or more, provided no radical improvement in pump design were effected.

In America we have had not only rapidly growing communities, but ingenious men and aggressive business managers who have been little hampered by labor union resistance to improved machinery. Hence obsolescence of machinery due to "improvements in the art" has played a very important part. I think I am safe in saying that the vast majority of machines in America have had a life averaging not to exceed about 20 years. Often the life of certain classes has

not been five years. Witness the short life of cable railways in our large cities, due to the rapid improvement in electric car transportation. Cableway systems had been hardly installed in New York and Philadelphia before they were torn out to make way for electric traction.

While the total actual life of a machine is usually independent of the amount of service it renders, but is usually determined by obsolescence, the life of the parts of the machine is determined by three factors: (1) The activity of use; (2) the care in lubrication, etc., to reduce wear; and (3) the amount and character of exposure to the elements.

Activity of use is an exceedingly important factor in the wear of most machine parts. Hence records of repair costs should give some statement of work done that will indicate the activity of the machine. Thus, the car-miles per year will show the activity of a car. The number of hours of actual work per year is often a sufficient index as to work done. A steam road roller usually works about 180 days of 10 hours, or 1,800 hours per year. A locomotive usually works nearly three times that number of hours, and its annual repairs form about three times as great a percentage of the first cost as the percentage of repair cost of a steam roller.

A rock drill working two shifts of 8 hours daily will show almost twice the annual repairs incurred when only one daily shift is worked. Incidentally, I may add that under severe and constant service, the annual cost of repairs of a rock drill may exceed the first cost of the machine.

Fortunately there are many classes of service that differ so little that annual repair costs or life of parts can be correctly judged without having at hand a statement as to the precise activity of the machine.

Let us now plot the costs of car repairs given in Table VI, so as to secure a curve of actual annual repairs. To do so we must first tabulate the recurring costs of renewals of parts given in Table VI as follows:

End of year.	Items repaired.	Total Repairs.
1	None	None
2	None	None
3	(3) Brasses	\$ 6
4	(1) Wheels	\$ 55
5	None	None
6	(3), (5) and (6)	\$ 26
7	(11)	\$ 3
8	(1), (2) and (8)	\$ 110
9	(3)	\$ 6
10	(9)	\$ 11
11	None	None
12	(1), (3), (5) and (6)	\$ 92
13	None	None
14	(11)	\$ 8
15	(3) and (7)	\$ 56
16	(1), (2) and (8)	\$ 110
17	None	None
18	(3), (5) and (6)	\$ 26
19	None	None
20	(1), (9), (10), (12) and (13)	\$ 86

Plotting the total annual repairs, for this 20 year period, we have the "curve" shown in Fig. 1, which bears no resemblance whatever to the "sinking fund curve of depreciation."

I have not carried the "curve" out to the 35 year period (the life of the truck frame), since our present purpose is fully served by considering the 20 year period.

Fig. 1. Repairs of Freight Car.

This saw-toothed "curve" of annual repairs of individual cars obviously will resolve itself into a straight line if the total annual repairs to a large number of different cars of slightly different ages is taken. During the first eight years of life of a group of wooden box cars, the total annual repairs will increase rapidly, but after that there will be comparatively little increase in the totals for each year.

The same general law holds of all machines in active and regular service. For a period there will be a rising cost of repairs, determined, as to rapidity of rise, by the life and cost of the various parts. Eventually the curve of repairs will become a saw-tooth line, whose general direction is either horizontal or slightly ascending. In no class of machine of which at present I have knowledge is there a repair curve bearing the remotest resemblance to a curve derived by plotting any function of any "sinking fund formula."

I should leave the discussion of this subject in somewhat incomplete form were I not to touch upon such structures (or parts of machines) whose life is terminated by the various forms of chemical change. The rusting of iron, the rotting of wood (due to fungi), the decay of asphalt (due to little understood chemical action), and various other forms of plant deterioration fall into one general class for which it may be possibly claimed that annual repairs of individual units follow some sort of regular curve, ascending rapidly toward the close of life. I think that the reasoning that has led to such a belief can readily be seen to be fallacious, if we start out by drawing a sharp distinction between the annual repairs required by a single unit and the annual repairs of a group of similar units.

Let us take a railway cross-tie of untreated yellow pine, for example. If we confine our attention to one tie, we shall find that for, say, 7 years it gives perfectly uniform service without requiring any particular attention. Then, perhaps, the qualities by virtue of which it has resisted decay, begin to depart, and rot fungus gains a hold here and there. The growth of this fungus under the rail may result in the decay of the wood fibres to such an extent that a spike works loose and the track foreman finds it necessary to pull the spike and drive it in another place. Some time later he may shift the tie slightly and redrive all the spikes. Finally he decides that the tie is so weakened by decay as to be unsafe, and removes it. The current repairs (the spike pulling, shifting, etc.) have been so slight in cost as to be entirely negligible when compared with the one great repair of entire renewal of the tie. Hence there exists no curve of repairs for this single tie at all, other than the one final upleap in the "curve," due to its renewal.

Let us see now what happens to a group of the same ties. Each tie differs slightly from the others, both in its physical and chemical make up. The character of the service differs also. One tie is near a rail joint, another is not. Some ties are on curves, some on tangents. Some are near soil where the spores of rot fungus are numerous, others are not. Hence at the end of, say, 5 years, some ties are so badly rotted that they must come out of the track; at the end of 10 years many ties are still in service, although the great majority may have been removed at the end of 2 or 3 years. Now if we plot the curve of annual tie renewals of this group of ties, we shall find it following the zero line for 5 years, then slightly ascending until about 8 years when it takes a sudden leap upward for a year or two—and all is over. This final action and sudden rise in the renewal curve indicates the somewhat varying life of the different ties, and nothing more.

The repairs of an asphalt pavement show a similar sudden rise toward the end of the life of the asphalt, and for similar reasons. Each square yard of the asphalt may be regarded as a unit similar to a railway tie. Slight original differences in chemical and physical constitution exist in the different square yards. Differences in severity of traffic exist in different places. Hence, as in the case of a group of railway ties of the same age, there will be differences in the life of different square yards of asphalt. This will show in the sudden rise of annual repairs of asphalt pavement after 15 to 20 years of life.

In general, any machine or structure consisting of a number of parts of equal age and subject to about the same exposure to the elements, or to wear, will have a curve of repairs that will eventually take a sudden rise. *This rise in repairs is simply the evidence of the termination of the life of the group of units composing the machine or structure.* If the machine or structure is of a kind that permits the economic renewal of each of those units by itself, as in the case of railway ties or rails, no problem in economics presents itself.

There is obviously nothing to do but to renew each unit as rapidly as it reaches the limit of its endurance.

If, on the other hand, the units are so interrelated that the renewal of single units is more expensive than the renewal of the entire group of units at one time, then a problem in economics does present itself, the question being this: When does the rising curve of cost of repairs to the expiring units reach a point where it becomes economic to abandon the entire group of units and procure a new group of units?

This problem is not one that comes before many classes of engineers, but it does present itself to highway engineers, particularly in connection with repairs to asphalt pavements. In view of this fact, and because several entirely erroneous solutions of the problem have been published by engineers eminent in the field of highway engineering, I have prepared a correct solution of the problem. (See page 27.)

While on the subject of repairs, it may be well to discuss briefly the identity of repairs and renewals in cases where a plant is being operated with a large number of plant units of different ages.

A railway is a plant for manufacturing transportation, as Wellington has well put it. The principal plant elements are:

1. Roadbed.
2. Ballast.
3. Ties.
4. Rails.
5. Buildings.
6. Rolling stock, or equipment.
7. Repair shops and tools.

Minor repairs of roadbed and track are being constantly made.

A bolt is renewed here, a spike there, a bit of ballast in another place—all renewals of plant on a minor scale. About 10% of the wooden ties are replaced annually—renewals again, though on a larger scale. About 5% of the rails are replaced annually—still more renewals. About 4% of the cars and locomotives are entirely renewed annually—renewals on a still larger scale. But from the worn-out track bolt to the worn-out locomotive, we have renewals of plant elements, varying in size and cost, it is true, but differing not one whit in the real character of the process.

Evidently, then, after any large plant has been in use for a considerable period of years, there is no logical reason for distinguishing between minor renewals (called repairs) and major renewals (called renewals, or "entire renewals"). They are all one and the same thing in fact, differing only in degree. Accountants have preached for a century or more about the dire consequences of failure to provide sinking funds for the redemption of large plant elements at the expiration of their life. But the great majority of managers of railways, lighting companies, mills, factories and mines, have ignored the arguments of the accountants, and have gone right on without providing a fund for renewals, but regarding renewals as identically the same in nature as repairs. In this I conceive that they have been right.

The managers and owners of plants have known, what accountants have ignored, that money is worth more to a company for use in extensions and betterments of plant than it could possibly bring by placing it in a sinking fund, since all sinking funds draw comparatively small interest. This has undoubtedly been a strong actuating motive—and a sound one—with plant managers, but I am satisfied that the inherent reasonableness of regarding even large renewals as repairs must have appealed quite as strongly to the managers of large plants.

Problem III. To Determine When Repairs Have Grown so Great as to Justify Renewal.—The following discussion can be understood only after a study of the preceding paragraphs.

This problem is one that seldom arises except in considering the repairs to such a structure as an asphalt pavement, for reasons previously given. If the rising "curve of annual repairs" is either a straight line or any curve which can be expressed as an equation, an accurate solution of the problem is possible by the use of the method about to be explained, aided by the application of differential calculus.

An approximate solution is possible even without resort to the higher mathematics, as will be now shown.

For simplicity of illustration, and not because it represents actual conditions, let us first assume that repairs increase at a uniform rate. It should be clear that the problem consists in finding the minimum quotient obtained by dividing the sum of the cost of the structure and the total repairs by the number of years during which the repair curve has been steadily rising.

Let

C = first cost of structure.

R = total repairs during y years of steadily increasing repairs.

Then when

$C + R$

— is a minimum we have the period beyond which it is
 y

uneconomic to continue repairs.

In other words:

The average annual first cost plus the average annual repair cost must be a minimum.

We need not consider the item of interest in first cost, for that is a constant that goes on forever, unaffected by the period of renewal of the structure. To those acquainted with calculus this statement should be self-evidently true, and to those who are not familiar with the higher mathematics it should become self-evident if they will consider the item of annual interest as being entirely analogous

Fig. 2.

to an expense for sweeping a street, a cost that depends, it is true, upon the character and therefore the first cost of the pavement, but one having no bearing upon the question of when an old pavement shall be replaced by a new one of the same sort.

Let us assume that the annual repairs rise steadily, at the rate of 4 cts. increase per year. Let us assume that the first cost of this asphalt is \$1 per sq. yd., not including the concrete base which is permanent, and therefore should not enter the problem any more than should the cost of sweeping, or the annual interest on the investment. Then we can show the "curve of repairs" as in Fig. 2.

By a series of approximations, we can now determine when the

$C + R$

value of — is a minimum. Let us first assume 5 years. Then
 y

$y = 5$. The total repairs during this five-year period can be readily

calculated by determining the area of the triangle ABO , in Fig. 2,

which is $\frac{20 \times 5}{2} = \0.50 .

Hence we have

$$\frac{C + R}{y} = \frac{\$1.00 + \$0.50}{5} = \$0.30,$$

which is the average annual first cost of the pavement and its repairs for the 5-year period. If this seems high, let us try a 4-year period. Then we have $R = \$0.32$,

$$\frac{C + R}{y} = \frac{\$1.00 + \$0.32}{4} = \$0.33.$$

Evidently, then, the economic period is not less than 5 years, and may be greater. Let us try 10 years. Then $R = \$2.00$,

$$\frac{C + R}{y} = \frac{\$1.00 + \$2.00}{10} = \$0.75.$$

This is much higher than for the 5-year period. Let us try 7 years. Then $R = \$0.98$,

$$\frac{C + R}{y} = \frac{\$1.00 + \$0.98}{7} = \$0.27.$$

Further tests will show that this is practically the minimum. It should be noted that the minimum is attained, in this case, when the total repairs for the period of rising repairs equals the first cost of the asphalt wearing coat. As a matter of fact, this is a law of general application wherever the curve of rising annual repairs is a straight line, that is wherever repairs increase annually by any constant percentage. I will prove this generalization by the aid of calculus, but it can be demonstrated in the more roundabout and primitive way above used.

In all cases, no matter what the curve of increasing repairs may be, the method of plotting the annual repairs and determining the area, to ascertain total repairs (R) will enable anyone to find when $\frac{C + R}{y}$ is a minimum, by a series of approximations.

For the engineer who is familiar with calculus the following method will afford a more direct solution of the problem. The problem is to determine when $IC + \frac{C + R}{y} = u$ is a minimum, u being the unit annual pavement cost.

When repairs increase regularly each year, by a rate α , then the equation of a straight line $x = \alpha y$ gives us the "curve of annual repairs." Since R is the area of a triangle whose base is y (see Fig. 2),

$$R = \frac{xy}{2},$$

$$\text{But } x = \alpha y,$$

$$\text{Hence } R = \frac{\alpha y^2}{2}.$$

Substituting this value of R in the equation

$$IC + \frac{C+R}{y} = u, \text{ we have}$$

$$IC + \frac{C}{y} + \frac{ay}{2} = u.$$

Differentiating, we see that IC (the annual interest) disappears, as it is a constant, and we have

$$-\frac{Cdy}{y^2} + \frac{ady}{2} = du.$$

Solving for a minimum by placing

$$\frac{du}{dy} = 0, \text{ we have}$$

$$-\frac{C}{y^2} + \frac{a}{2} = 0,$$

$$y^2 = \frac{2C}{a},$$

$$y = \sqrt{\frac{2C}{a}}$$

This gives us the desired formula for determining the time (y)

Fig. 3.

when it becomes economic to renew the entire pavement. If, as in the example above given, $a = 4\%$ of C , we have

$$y = \sqrt{\frac{200}{4}} = 7.07 \text{ years.}$$

Since the minimum average annual plant expense is attained when $y = \sqrt{\frac{2C}{a}}$, and since $R = \frac{ay^2}{2}$, we have

$$R = \frac{a}{2} \times \frac{2C}{a} = C.$$

Hence:

When annual repairs increase steadily by a constant ratio it ceases to be economic to retain a structure or machine in service after the aggregate repairs exceed the first cost of the structure or machine.

Should the structure or machine have any salvage value, substitute the expression "first cost minus salvage value" in the foregoing criterion in place of the expression "first cost."

As a further example, let us assume that the curve of annual

repairs is a parabola instead of a straight line, as indicated in Fig. 1.

The area ABO gives us the total repairs, or R ; and for a parabola this external area is

$$R = \frac{xy}{3}$$

Since the curve of the parabola is

$$y^2 = 2px, \quad x = \frac{y^2}{2p}$$

Hence

$$R = \frac{y^3}{6p}$$

Our equation of condition is, as before,

$$\frac{C + R}{y} = u$$

Hence

$$\frac{C}{y} + \frac{y^2}{6p} = u$$

Differentiating and placing

$$\frac{du}{dy} = 0, \text{ we have}$$

$$\frac{-C}{y^2} + \frac{ydy}{3p} = 0,$$

$$y^3 = \frac{3pC}{3p},$$

$$y^3 = 3pC,$$

$$y = \sqrt[3]{3pC}.$$

Substituting the values of p and C in this equation will give us the period of years during which it continues to be economic to pay the increasing cost of repairs.

Since $R = \frac{y^3}{6p}$, and since $y = \sqrt[3]{3pC}$, combining we have

$$R = \frac{C}{3}$$

Hence:

When annual repairs increase steadily according to the curve of a parabola, it ceases to be economic to retain a structure or machine in service after the aggregate repairs exceed half the first cost of the structure or machine.

In the case of an asphalt or block pavement, annual repairs are usually very slight for a considerable term of years, the repairs often amounting to nothing at all. Let us assume that for K years there are no repairs and that then the repairs increase uniformly at the rate a for s years. Then the annual repairs (x) at any given year after the period of no repairs are given by this equation

$$x = as$$

And the total repairs are

$$R = \frac{xs}{2} = \frac{as^2}{2}$$

The average unit cost (u) of repairs per year is

$$u = \frac{C + R}{K + s}$$

$K + s$ being the total life (y).

Substituting for R its value $\frac{as^2}{2}$ we have

$$u = \frac{C + \frac{as^2}{2}}{K + s}$$

As before, solve for a minimum by differentiating and placing the first differential coefficient equal to zero. To do this, let

$$K + s = y$$

Then

$$u = \frac{C}{y} + \frac{as^2}{2y}$$

$$du = \frac{-Cdy}{y^2} + \frac{a}{2} \left(\frac{2ysds - s^2dy}{y^3} \right)$$

But, since $K + s = y$, $dy = ds$, hence

$$du = \frac{-Cdy}{y^2} + \frac{a}{2} \left(\frac{2ysdy - s^2dy}{y^3} \right)$$

Then if we make $\frac{du}{dy} = 0$, we have

$$-C + \frac{a}{2} (2ys - s^2) = 0$$

$$-s^2 + 2ys = \frac{2C}{a}$$

But $y = K + s$, hence

$$-s^2 + 2(K + s)s = \frac{2C}{a}$$

$$s^2 + 2Ks = \frac{2C}{a}$$

$$s^2 + 2Ks + K^2 = \frac{2C}{a} + K^2$$

$$s + K = \sqrt{\frac{2C}{a} + K^2}$$

But $s + K$ is the economic life (y) of the pavement, hence expressed in words this formula becomes:

When a structure requires no repairs for a period of years (K), and then the repairs increase annually by a regular rate (a), the economic life (in years) of the structure is equal to the square root of the sum of (1) twice the first cost (in dollars) of the structure divided by the rate (a) and (2) the square of the number of years (K) of no repairs.

Thus if the period of no repairs (K) is ten years, and if the repairs then start and increase steadily at the annual of rate (a)

of 0.04 (or 4%) of the first cost, and if the first cost (c) is \$1, we have:

$$\text{Economic life } (s+K) = \sqrt{\frac{200}{4} + 100} = \sqrt{150} = 12.25$$

Hence the economic life would be 12.25 years, or only $2\frac{1}{4}$ years after the 10 year period of no repairs has expired.

In like manner formulas can be readily deduced for any other curves of repairs.

Having now before us a mathematically correct method of solving problems of this nature, it may be well to examine at least one of the incorrect solutions that have previously been published. In the following paragraphs will be found an erroneous method of attacking this problem.

Fallacious Formula For Determining When Increasing Repairs Justify Resurfacing a Pavement.—In 1906, Mr. George M. Tillson, Chief Engineer, Bureau of Highways, Brooklyn, New York City, read a paper* before the Mechanical and Engineering Section of the Franklin Institute, in which a method was given for solving a problem that often comes before highway engineers. Mr. Tillson said: "It is often desirable to know positively when the cost of repairing a pavement has become so great that it would be economical to relay the pavement. This can be determined by the same formula, as its result governs the cost of maintaining the pavement perpetually, so that when the annual repairs equal or exceed the perpetual annual cost, it is time to repave."

The formula to which he alludes is $A + CI + \frac{R}{N}$ = annual expense, in which

N = life of pavement in years.

C = first cost per square yard.

I = rate of interest.

A = amount to be paid in each year to create a sinking fund to equal C in N years.

R = total cost of repairs.

Mr. Tillson gives the following example:

"Take for instance an asphalt pavement and let N equal 15 years, C equal \$1.50, I equal 0.035, and R equal \$0.40. Then A will equal 0.0807 and the equation becomes $0.0807 + 0.0525 + 0.0267 = \0.1599 ; or if the street be repaved it will cost annually \$0.16 till it is renewed. Consequently if the life of asphalt be correctly assumed at 15 years, it should not be repaved until the annual cost approaches \$0.16 per sq. yd. Assuming the life to be 20 instead of 15 years and applying the formula as before, the annual cost will be reduced to \$0.1356 per yard. The author believes this is the true scientific way in which to determine when an asphalt pavement, from an economical standpoint, should be relaid."

The problem that Mr. Tillson undertakes to solve is when a pave-

*The paper was reprinted in full in *Engineering-Contracting*, July 17, 1907.

ment should be relaid. Therefore the unknown quantity should be y , the number of years of economic life; but where does y appear in Mr. Tillson's equation? It really exists on both sides of the equation and is not transposed to one side before solving. If we study Mr. Tillson's method, we see that it amounts to this: His equation of condition is that when current repairs (r) for any given year equal "average annual cost," then it is time to renew the pavement. But we have seen that his assumed average "annual ex-

pense is $A + GI + \frac{R}{N}$. Now, calling the current repairs for any given year r , we have

$$r = A + GI + \frac{R}{N}.$$

This is the equation that we are to solve. Where is y , the number of years? If the repairs are increasing annually—and that is one of the conditions of this problem— r must be a function of y , so we have y on the left side of the equation. What is R ? R is the total cost of repairs during the life y , so R is also a function of y . Hence the very thing we are trying to ascertain is assumed in the

expression $\frac{R}{N}$.

Yet this is not the only place where it is assumed, for the amount to be paid annually into a sinking fund, A , is also a function of y . Hence one function of y is placed on the left side of the equation, and two functions of y and a constant are placed on the right side. We are then told that if we will juggle with the variable, y , until there is an equality, we have solved for y . Further comment on such misuse of mathematics appears to be unnecessary.

Straight Line Formula of Depreciation.—The most common way of determining the depreciated value of a machine, where appraisal of physical property is being made, is by the "straight line formula of depreciation." This consists simply in regarding each lost year of plant life as causing a depreciation proportionate to the entire loss of value at the end of its life. In other words, the rate of annual depreciation is $1 \div$ the total number of years of life. Thus, when the average life of a railway tie is 10 years, each year causes a depreciation of $1/10$, or 10% of the first cost of the tie. At the end of 8 years it has lost 80%, and its depreciated value is 40%.

For some purposes of appraisal of present value of plant units, this method is, perhaps, satisfactory. Its simplicity appeals to all. But with increased knowledge as to life and cost of plant repairs, this simple method is likely to give way to the exact method of the Unit Cost Depreciation Formula (page 36).

It should be remembered that where a plant contains a large number of similar plant units of varying age—as in the case of all old railways—the average annual renewals are identically the same as the annual depreciation obtained by the straight line

formula. Thus if locomotives average a life of 25 years, annual depreciation by the straight line formula is 4%, and if the locomotives are of equal value but of different ages, annual renewals will be exactly 4% of the cost new.

As I have stated elsewhere, this condition makes it unnecessary to use a sinking fund table for determining depreciation, since renewals of entire plant units are regarded as identically the same as renewals of parts of each plant unit commonly called repairs.

The Bastard Straight Line Formula of Depreciation.—It is not an uncommon practice to "write off" a certain percentage for plant depreciation each year. When the amount written off is a fixed percentage of the first cost of the plant there is an application of the straight line formula of depreciation. However, it is the practice among many accountants to "write off" each year a percentage of the last year's "book value" of the plant. This produces a curve of "depreciated value of plant" that rapidly flattens out, and extends to infinity. There is certainly no logical defense possible for this method of estimating depreciated values.

Sinking Fund Formula of Depreciation.—According to this method it is assumed that the total depreciation of a machine or structure at any given age is the amount already accumulated in a sinking fund established for its redemption at the end of its life.

Table IV (page 15) gives the accumulation (a) of \$1 for any number of years (n).

Table III (page 13) gives the annual deposit (p) in a sinking fund to redeem \$1 at the end of the life of the machine, that is at the end of N years. Hence the accumulation in n years of an annual deposit of d will be

$$(16) \quad A = d \times a,$$

d being taken for N years (life) from Table III,

a being taken for n years (age) from Table IV.

But, as previously shown in explaining these two tables,

$$a = \frac{1}{d^2},$$

d^2 being taken for n years from Table III. Hence,

$$(17) \quad A = \frac{d}{d^2},$$

d being taken for N years (life) from Table III,

d^2 being taken for n years (age) from Table III.

Equation (16) is the most convenient for general use, but it is well to remember that equation (17) is equally applicable.

To illustrate by an example let us determine the depreciation of a railway tie 6 years of age, whose total life will be 10 years. If we assume a rate of interest of 4% we have by formula (17) and Table III

$$A = \frac{d}{d^2} = \frac{.0819}{.1508} = 55\% \text{ nearly,}$$

which is the percentage of depreciation or lost value.

Since the depreciation by this sinking fund formula is 55% of the first cost, the present value is 45%.

By the straight line formula the depreciation is 60% and the present value is 40%.

The same result (55% depreciation) is obtained with more expedition by the use of equation (16) and Tables III and IV.

Depreciation curves have been prepared from calculations made in this manner, and will be found at the end of the Waterworks Section of this book, for which consult the index under "Depreciation, Sinking Fund Curves."

The arguments upon which this method relies for support are two: (1) That the redemption of all perishable plant units should be provided for by sinking funds, and that, consequently, the accumulation in a sinking fund at any time represents the depreciation of the plant, which if delivered to a purchaser of the plant would recompense the purchaser in full for the plant depreciation. (2) That a sinking fund curve of increase, year by year, is analogous to the curve of increased cost of plant repairs.

The first argument looks sound, but is really fallacious. The purchaser is asked to accept a fund in place of an actual loss of value of the plant which may bear no relation to the fund at all.

The second argument is even more faulty, for by the wildest stretch of the imagination there can be found no logical relation between the annual cost of repairs and a sinking fund curve, since the one is the result of physical and chemical action, while the other is a function of rates of interest on capital.

We have already seen that the actual curves of plant unit repairs are not regularly ascending curves at all. And we have also seen that certain numerous classes of plant units have no appreciable repairs, save the final upheav in the curve which marks the entire renewal of that plant unit. It is, therefore, apparent that the sinking fund formula will not remain long popular after engineers have a clearer conception of the nature of plant repairs, and particularly after the fundamental principles of estimating unit costs of production are better understood.

In the following paragraphs will be found a determination of depreciation based upon the criterion of unit costs of production, which is the only criterion by which relative plant values can ever be accurately determined.

The Unit Cost of Depreciation Formula.—In selecting a name for the formula that I have deduced below, I have been somewhat at a loss to choose a title that would be descriptive of the principle involved, without being too cumbersome. For brevity it seems well to call it The Unit Cost Depreciation Formula.

The owner of a secondhand machine is entitled to such a price for it as will enable the purchaser to go on with its use and produce each unit of product at as low a cost as the average unit cost of production would be during the entire life of the machine.

This is but common equity, and needs no argument in its support. The equitable price thus arrived at is the depreciated value

of the machine. It will be noted that the criterion thus announced is essentially the same in principle as the criterion used in Problem I, for determining which of two new machines to select (page 17).

Adopting similar symbols we have:

N = annual average, number of units of product of machine during its entire life.

n = annual average number of units of product of the old machine during its remaining years of life.

C = first cost of a new machine.

c = depreciated value of old machine.

D = sinking fund annuity (Table III) to redeem first cost (C) of new machine at end of life.

d = sinking fund annuity (Table III) to redeem depreciated value (c) of old machine during its remaining term of years of life.

R = rate per cent of average annual repairs during entire life.

r = rate per cent of average annual repairs during remaining

life.

$T = r n$ = total repairs during remaining life.

I = interest on capital.

O = average annual operating expense during entire life.

o = average annual operating expense during remaining life.

U = average unit cost of production during entire life.

u = average unit cost of production during remaining life.

Then

$$(18) \quad U = \frac{O + RC + DC + IC}{N}$$

$$(19) \quad u = \frac{o + r n + d n + I n}{n}$$

But $r n = T$, hence

$$(20) \quad u = \frac{o + T + d n + I n}{n}$$

According to the principle that U should equal u , we have

$$(21) \quad \frac{O + RC + DC + IC}{N} = \frac{o + T + d n + I n}{n}$$

In all ordinary cases, $O = o$, and $N = n$, hence

$$(22) \quad RC + DC + IC = o + T + d n + I n$$

Therefore,

$$(23) \quad C = \frac{C(R + D + I) - T}{d + I}$$

Formula (23) gives the depreciated value of a secondhand machine or structure. If it is desired to express this depreciated value as a percentage of the first cost C , we have

$$(24) \quad \frac{o}{C} = \frac{(R + D + I) - T}{d + I}$$

Formula (24) is our unit cost depreciation formula.

If repairs during the entire life are nominal in amount, then both R and T vanish, and we have

$$(25) \quad \frac{C}{C} = \frac{D+I}{d+I}$$

Formula (25) is the one to apply to railway ties, water pipe, and other plant units that have no appreciable current repairs.

For contrast with the sinking fund formula, let us find the depreciated value of a railway tie 6 years old, whose life is 10 years, interest being 4%.

Table III (page 13) gives:

$D = 0.0833$ for 10 years, and 4%.

$d = 0.1508$ for 6 years, and 4%.

Then according to equation (25) we have

$$\frac{C}{C} = \frac{8.33 + 4}{15.08 + 4} = \frac{12.33}{19.08} = 64.5\%.$$

We have seen that the sinking fund formula gives a depreciated value of 45%, and that the straight line formula gives 40%, with the same data as to life, age, etc.

Contrast formula (25) with formula (17), and it will be seen that the sinking fund formula differs in not having I added to both numerator and denominator.

Contrast formula (25) with formula (17), and it will be seen that the sinking fund formula errs to an even greater extent, for it makes no rational provision for consideration of the actual repairs during the whole life and the remaining life of the machine.

So far as I know, these formulas (24) and (25)—unit cost depreciation formulas—have never been deduced before. Formula (25) lends itself as readily as the sinking fund formula to being plotted as a curve. Formula (24) can also be expressed as a curve, when the actual rates of repairs are known, but it does not lend itself to any guesswork, which, after all, is a real merit. There has been too much guessing as to rates of repairs.

Physical Property Valuations.—As a result of the growing control that governments are exercising over public service corporations, as well as because of the tendency to place all property values on a scientific basis for taxation, there have been many recent appraisals of the physical, or tangible, property of railways, lighting companies, etc. Many more such valuations will be made in coming years, and will require the constant services of many engineers in keeping the valuations up to date. Moreover, I am inclined to believe that the valuation of the physical property of all large corporations will eventually be made by governments, if for no other reason than to protect stockholders from unscrupulous company officials, who by insufficient maintenance of plants can make net earnings seem to be larger than they really are, and thus inflate stock values for a time, only to reverse the process and cause a slump. No scientific expenditure for proper plant maintenance is possible without a knowledge both of the character of the plant and the service it is rendering but of

the amounts of capital invested in the various plant units. This is tantamount to saying that no one can judge accurately from reports of annual maintenance expenditures whether a large plant is being properly maintained unless a detailed appraisal of the physical property is at hand. This alone would justify every railway and every large manufacturing company in having a physical appraisal made and kept up to date, for its own purposes. Some, in fact, do, but they are woefully in the minority as yet.

A physical appraisal involves ascertaining all unit quantities of construction, and the number of plant units of each class, to which standard present prices are applied. This gives the cost of reproduction *new*.

The next step is to ascertain the average age of the units of each class, for the purpose of estimating *depreciated value*, or, as it is more often called, *present value*. We have just seen that three formulas are now available for this purpose: (1) The Straight Line Depreciation Formula; (2) the Sinking Fund Depreciation Formula; and (3), one that I now submit for the consideration of appraising engineers, the Unit Cost Depreciation Formula.

In the Railway Section of this book I have discussed the proper method of arriving at the average age of plant units of the same kind, but differing in first cost. (See the Index under "Appraisal, Railways"; also see "Appraisal, Waterworks").

Going Concern Value.—In addition to the first cost of a plant, including the interest on the investment during construction, there is another sort of expense that should properly be included in arriving at the cost of the plant to its owners, and that is the cost of getting the business.

For some years after a plant is put in operation, it frequently is run at an actual loss, until its products become favorably known to the public, or until the development of its tributary population supplies the business.

The early losses in operating a plant should usually be regarded as actual expenditures in developing the business, and should be figured at compound interest up to the time that there ceases to be a loss from operation.

And now comes a very important point to bear in mind when determining these operating losses, namely that during the early years of a plant operating expenses (including maintenance in the term) are below normal. This results from the fact that new machinery requires little or no repairs. In equity, therefore, not the actual repairs should be considered but the annual sinking fund deposit necessary to provide for the excess repairs that must be borne in later years.

Having thus determined the full theoretical maintenance (actual plus proper annual allowance for sub-normal repairs), and operating expense, there comes a time when there ceases to be a loss from operation and when the earnings also suffice to pay the interest on the bonds, or the capital invested. Still, money continues to be expended in advertising and in soliciting new business. This

money is also an element of cost in establishing the business, and, as such, is to be regarded as a part of the cost of the plant and its business.

The sum of the money lost at first in operating the plant, and the money spent in advertising, soliciting business, etc., may be called the going concern value of the plant, which should certainly be added to its physical value.

A further discussion of this subject appears at the end of the Waterworks Section. Consult the index under "Value, Going Concern."

Commercial Valuations.—The method of valuing an existing business is one of comparative simplicity, unless there is doubt as to physical condition of the plant. In which case a physical valuation of the plant may be needed to determine what the excess cost of repairs is likely to be due to a run-down condition.

When this does not enter the problem, the question is simply one of ascertaining the net earnings and of capitalizing them at a rate of interest which judgment in such matters dictates as being reasonable. If the business is large and long established, the rate of interest used in capitalization may be as low as 5%, provided "net earnings" are regarded as the remainder after deducting operating expense, maintenance and interest on the investment (= interest on bonds).

This is, as low a basis as is apt to be used, unless the curve of growth of the business is such as to warrant favorable speculation as to its future, or a discounting of the future by assuming a lower rate of interest as a basis for capitalization.

When a business is small and subject to fierce competition of capable rivals, and is dependent for its present success largely upon one or more individuals, the rate used in capitalizing its net earnings should be very high. In this connection it may be well to caution the young engineer against being deceived as to the operating expense of a small business. The owner of such a business frequently draws only a small salary, and looks to the dividends or profits for his real salary. When he has sold the business, it will probably be necessary to hire a manager of ability equal to that of the owner, and to pay him a much higher salary than the owner drew.

It is a curious fact that this consideration has escaped the attention of not a few men who have appraised the value of small business concerns. One celebrated English promoter made several fortunes by capitalizing comparatively small business concerns on net earnings shown truthfully in their books, but which did not show that the mental equal of the old owner of the business could not be hired except for a very large salary.

An interesting discussion of the commercial valuation of railways will be found in Bulletin 21, Department of Commerce and Labor, Bureau of the Census, entitled "Commercial Valuation of Railway Operating Property in the United States, 1904"

Prof. Henry C. Adams, Prof. B. H. Meyer, and Mr. William J

Meyers give many valuable data in the course of the discussions in the Bulletin No. 21, which contains nearly 90 pages.

From a great array of railway statistics, Mr. William J. Meyers concluded that railway bonds averaged a return of 3.793% on their market price, and that railway stocks averaged a return of 4.918% on their market price. He says: "Combining the figures for shareholders' interests with those for the funded debt (bonds) we get as the mean rate of annual return on all securities 4.256%, which is thus indicated as the proper rate to be used in capitalizing net earnings from operation (diminished by taxes) in order to arrive at the value of the security holders' interests in the operating property."

How to Prepare Estimates and Bids.—In estimating a unit price for any kind of work, contractors often place too much reliance on published prices for similar work. There are seven serious sources of error in so doing: (1) The conditions may vary greatly in places but a few miles apart; (2) rates of wages often vary widely, being, for example, higher in large cities than in small cities or in the country; (3) specifications and the interpretations of identical specification clauses by different engineers vary greatly; (4) contractors inexperienced in the particular work in question often have bid prices altogether too low; (5) the bidding prices may be purposely unbalanced, being too high on certain items and too low on others; (6) a unit price that is fair for a large job is generally too low for a small job; (7) a contractor already equipped with a plant can often afford to bid lower than the contractors not so equipped.

While previous bidding prices should be used as a guide, they should never be relied upon implicitly if the work is of any considerable magnitude. Each item should be estimated in detail, and this estimating should be done systematically to avoid some serious omission. The cost of any item of work may be divided into five parts:

1. Development expenses.
2. Plant expense and supplies.
3. Materials.
4. Labor.
5. Superintendence and general expense (overhead charges).

Development expense includes the cost of making roads, delivering and installing the plant, draining the site of the work, salaries of foremen and others on the idle list pending the beginning of work, and all expenses involved in getting ready to build the structure. On small jobs this item of development expense is often a very large percentage of the total cost; and on large jobs it seldom can be neglected in estimating probable unit costs.

Development expense has to be estimated for each particular job, by securing freight rates or estimates for carting, etc. In some cases it includes temporary road building, installing pipes for water supply, etc.

Plant expense includes interest, repairs, depreciation and in-

insurance on all tools, machines, buildings, stored materials, trestles, falsework; and supplies include fuel, oil, etc.

Materials include only such materials as actually go into the finished structure, and the wastage of materials due to breakage in handling or sawing and shaping. The cost of materials includes freight and hauling to the site of work.

Labor includes all skilled and common labor, except superintendents, clerks and office men.

Superintendence and general expense includes foremen, managers, timekeepers, watchmen, bookkeepers, supply clerks, rents, taxes, travelling and entertaining expenses, stationery, etc.

To the experienced contractor an enumeration of these items may seem unnecessary, but it is indeed surprising to see how often inexperienced contractors err through failure to consider all of these items. Engineers, and not always young engineers, are prone to omit development and plant expenses, either in whole or in part, from their estimates of cost.

Returning to the subject of deciding upon bidding prices, make it a practice always to check the quantities given in the bidding sheet as far as possible. If the contract is a large one, or the work is such that you cannot personally do all the checking, employ an engineer to do so. It is astonishing to note the number of errors, typographically or otherwise made, that creep into quantity sheets. An error of transposition is not uncommon; thus, the engineer may have correctly determined that there are 2,000 cu. yds. of embankment and 1,200 cu. yds. of riprap, but in the bidding sheet the quantities may be transposed so as to read, 1,200 cu. yds. of embankment and 2,000 cu. yds. of riprap. In looking over the quantities, therefore, always ask yourself whether each quantity "looks about right," or not. A shrewd contractor will thus discover errors that a whole staff of engineers have overlooked. Whenever you see a small, and what appears to be an arbitrary quantity, like 10 cu. yds. of concrete or 50 cu. yds. of rock excavation, look carefully over the plans and specifications to discover if possible where this quantity is shown in detail. If it cannot be found that the quantity has been actually measured, it is safe to assume that it has been guessed at, and that in consequence it may subsequently prove to be an under-estimate. Bid liberally on such items, but bid not too liberally. More contractors, otherwise shrewd, than one would expect to see make the error of bidding unreasonably high on such small items. The result sometimes is that their bids are rejected because they are "unbalanced"; or, if accepted, and later it is found that a larger quantity of the unbalanced item exists, the engineers may either change the plans or relet the work covering that item. Set it down that seldom is it good business policy to bid an unreasonably high price on any item even on public works contracts, and it never is wise to do so on private contracts. Even though the item is small, and the cost of putting up a plant to perform the work is large, still bid only a little higher price on the item than you would bid if it

were many times larger, and distribute the estimated cost of plant over the other items.

A Schedule of Items of Cost.—In preparing an estimate of unit cost there is always danger of omitting some important item. To avoid such an omission I find it desirable to compare my estimates with a schedule of items, such as follows:

1. Cost of temporary roadways
2. Cost of right of way through farms, etc.
3. Cost of clearing and grubbing the site.
4. Cost of snow removal and draining the site.
5. Cost of the site.
6. Cost of sheds, barns, offices, etc.
7. Cost of delivering and installing plant.
8. Cost of supplies, including explosives, water, fuel, oil, etc.
9. Plant, interest, depreciation, and repairs.
10. Cost of shifting plant units from one point of attack to another, including lost time of workmen waiting during the shifting.
11. Cost of trestles, falsework, bracing, forms and temporary supports.
12. Quarry rent, sand pit rent, timber stumpage, etc.
13. Cost of materials f. o. b. for a unit of the structure, including wastage.
14. Freight on materials.
15. Cost of unloading, hauling and storing of materials.
16. Cost of delivery and re-handling materials until at the place to be used.
17. Labor of handling, shaping and placing materials, and all operating labor.
18. Foremen's salaries.
19. Salaries of watchmen, timekeepers, clerks, bookkeepers, etc.
20. Office and traveling expenses.
21. Interest on cash capital other than plant.
22. Taxes, licenses and insurance of property.
23. Insurance of workmen and the public against accident.
24. Premium paid to bondsmen or surety company for bond required.
25. Advertising, legal expense, charity.
26. Discount on warrants, notes or other paper payments for work done.
27. Riot protection and detective work.
28. Sanitation.
29. Housing plant during winter.
30. Providing waterproof garments.
31. Engineering.
32. Percentage added to materials and percentage added to labor, to cover contingencies.
33. Percentage for profit.

Plant Expense.—Plant expense is commonly underestimated. First it is necessary to consider the time limit allowed for the

work. Then a plant must be figured upon that will perform the work at least 20% within the time limit, making also liberal allowances for bad weather delays, as well as for delays in delivering and installing the plant, and delays due to breakdowns.

Use with great caution the figures of output given in most catalogs; they are almost invariably based upon ideal conditions, and not infrequently are wholly deceptive. Even where the output of a machine is correctly stated, remember that such an output may not be possible in your case, due to inability to get materials to the machine or away from it. Consider always the limiting factor. A derrick, for example, may be able to handle 200 cu. yds. a day, but if it serves a few men working in a confined space, its actual output may not be 30 cu. yds. Time and again this self-evident fact has not been evident to the inexperienced man.

To give another example, suppose the work is rock excavation. Do not guess at the number of rock-drills required; but estimate the probable spacing of the drill holes in the given kind of rock and from this calculate the number of cubic yards of rock each drill will break daily on a basis of, say, 50 ft. of hole drilled per machine per shift. Knowing the time limit, compute the number of drills required; and, knowing the number of drills, compute the boiler power required. Guess at nothing. If you have no other data, secure, by letter, some estimates of output from the large and old manufacturing firms, whose estimates are frequently very close to the truth.

Allow liberally for plant that is idle during shop repairs. On railways, for example, 8 to 12% of the total number of locomotives are constantly in the shop undergoing repairs.

Having liberally estimated the size and kind of plant required, and having secured quotations on the plant, charge the full cost of the plant up to the job to be done, and determine how many cents per yard, or per other units involved, are thus chargeable to first cost of plant. This will give a maximum charge, and it is well to know the worst. But if the full cost of a plant is charged to a small job, some other contractor will probably get the work. Go, therefore, to a dealer in second-hand machinery, and ask him to name a fair price on a second-hand plant such as yours will be when you are through with it. If you can secure a tentative bid on the machinery, you will have a fairly reliable estimate of the salvage value. In most cases you can form some estimate of the salvage value, by finding what second-hand plants are selling for. If you are still afraid that your charge for depreciation will be so high as to lose the job, there is left just one safe way of estimating, namely, to secure a rental quotation. There are many firms who make a business of renting contracting plants, and such a plant as is wanted can usually be rented for a daily or monthly price that includes ordinary wear and tear. The longer the plant is to be used the lower the daily rate of rent, therefore be careful to secure a sliding scale lease. A hoisting engine and boiler may be rented for, say, \$2 a day, if the period is to be 30 days; but, for each added

10 days, there should be a reduction in the rate, down to, say, \$1. beyond which no further reduction is given. The reason why such a sliding scale can be secured is briefly this:

The season for contract work is usually limited; road work, for example, is limited to the summer and fall months. Most of the contracts are awarded at an early date, so that if a plant remains unrented well into the season, the chance of renting it falls off rapidly. Periods of idleness between times of rental soon cut down the net income from a plant, yet interest on the investment goes on uninterruptedly. If these periods of idleness can be reduced the owner of a plant can afford to accept a lower per diem rate of rental, yet be a gainer at the end of the year.

Then, too, there are some seasons when contractors and their plants are abundant, and work is scarce. The revenues from such plants are then correspondingly small.

I have found that a roadmaking plant does not average 100 days actually worked per year. A 10-ton steam roller costs, say, \$2,500; and, if interest is charged at 5% per annum, we have \$150 to be distributed over 100 days—not over 365 days, as many engineers have done.

Depreciation, of course, does not go on as rapidly when a plant is idle as when working, provided the plant is properly housed and cared for; but the housing and the care cost money. Moreover, many kinds of machines become obsolete in a few years, so that depreciation cannot be said wholly to cease while the plant is idle. All the annual repairs and depreciation and all the cost of housing and caring for the plant should be distributed over the average number of days actually worked. If, on a 10-ton steam roller, the annual depreciation is \$200, we have $\$200 \div 100$, or \$2 per day worked; and if we add to this the \$1.50 per day charged to interest, we have a total of \$3.50 per day worked. Now, such a charge should be made by the contractor even where he uses his own roller.

It may be asked why the interest, repairs and depreciation are distributed over the days actually worked. The answer is that the output of the plant is usually estimated as so and so many units per day, and that, in consequence, all costs should be reduced to the same basis.

In such states as New York there are only about 3 months of the year, and about 21 or 22 days per month, suitable for economic outdoor work of the class of earth excavation. Weather records will enable any one to predict with reasonable accuracy the number of working days per year in any locality.

Cost of Superintendence and General Expense.—The cost of foremanship on contract work seldom exceeds 15% of the cost of labor, and it seldom runs much below 5%. If one must guess, perhaps 10% is a fair average. These percentages include the salaries of foremen only. The salaries of general superintendents and office men, and all office expenses are preferably called "general expenses" or "fixed expenses." General expenses seldom amount to less than 1%, and on small, intermittent job work they may run much higher.

In estimating supervision by the percentage method, care should be taken to exclude the cost of materials and to base the estimate upon the labor only. As an illustration: The General Expenses for the average American railway are 3.9% of the total expense of operation (including maintenance), distributed as follows:

	Per cent.
Salaries of general officers	0.826
Salaries of clerks and attendants.....	1.372
General office expenses and supplies.....	0.263
Insurance	0.481
Law expenses	0.452
Stationery and printing (general office).....	0.182
Other expenses	0.300
Total general expense.....	3.876

This does not include superintendence of "maintenance of way," or of "maintenance of equipment," nor of "conducting transportation." The first of these items is not reported separately, but we shall assume it to be the same as maintenance of equipment since the gross expense for maintenance of way is practically the same as for maintenance of equipment.

	Per cent.
Maintenance of way (assumed).....	0.561
Maintenance of equipment.....	0.561
Conducting transportation.....	1.776
	2.898

This gives a total of practically 3% for superintendence and 3% more for general expense if we exclude "insurance" and "law expense" from general expense. But this combined 6% is 6% of the gross operating and maintenance expense, only 60% of which is labor, the remaining 40% being for materials, supplies, etc. Hence, the percentage based on labor alone is 10% for general expense and superintendence, about equally divided between the two. For further study of these, see the Railway Section.

For data on the expense of engineering supervision of public works, see the Surveying and Engineering Section.

Throughout this book are numerous data on costs of supervision, for which consult the index under Supervision. Also consult the index under General Expense.

Percentage to Allow for Contingencies.—After estimating the probable cost of every item of work as closely as possible, including superintendence and general expenses, a percentage should generally be added for contingencies. A very common allowance is 10%; but no such rough guessing is indulged in by either a careful engineer or by an experienced contractor.

Contingencies is an item used to insure against oversights and ignorance. On work where sub-contracts can be let at once for the materials, there is practically no risk taken on materials, hence there is no justification, on the part of the contractor, in making an allowance to cover contingencies on materials. The engineer who designs a structure may be justified in making such an allowance to cover possible bills for "extras," but not otherwise. On the other hand, it is often wise to make an allowance to cover pos-

able inefficiency of laborers, or possible strikes, or possible rise in rates of wages; for, after estimating the average cost of labor on a given structure, there is always some risk of exceeding the average, for some unforeseen reason. On large jobs both the designing engineer and the contractor are justified in adding from 5 to 10% to estimated labor costs to cover contingencies. If the price of materials has been steadily rising, then a study should be made of price curves extending over several years in order that some rational allowance may be made for the probable rise in prices of materials before they can be sub-contracted for. If, on the other hand, prices are on the downward curve, a contractor may feel justified in bidding lower than he otherwise would. The best way to arrive at an allowance for contingencies is to keep a full record of the estimated cost of each item of work, and subsequently compare it with the actual cost. In this way it will be found that there is seldom a job on which every item of cost can be accurately predicted.

Percentage to Allow for Profits.—The common method of adding uniformly 10 or 15% for profits is open to serious objections, among which are the following: (1) The percentage to add for profits on materials should usually be less than the percentage to add for profits on labor, particularly when profits and contingencies are lumped together; (2) the time element and the size of the job should always be factors in considering profits, for profits are, strictly speaking, the salaries of the contractors; (3) the number of dollars' worth of contract work that can be secured and handled each average year must be considered, for the reason just given; (4) the percentage for profits is often made to include interest on plant and on cash capital invested, and, if so, there is added reason for not using a uniform percentage like 15%.

That there is need of calling attention to these elementary principles is apparent when one notes erroneous statements found in many text-books.

On materials, such as brick, timber and steel, that can be bought by sub-contract immediately after the award of the main contract, one may estimate a low profit, say, 10 or 15%; but on labor the profit should usually range from 15 to 25%, or even higher if contingencies are included in the percentage allowed for profits.

On contract work that can be done only during a few months of the year, and especially on work requiring a large investment in plant, such for example as macadam road work, the percentage of profits must usually be above the average of the percentage on work that extends over a longer period. If engineers fully realized the importance of this fact they would be at more pains to award all highway contracts early in the spring of the year, so that a longer season would be available than is now the case.

Causes of Underestimates.—Engineers have been said to be men who can be relied upon in every respect save one—ability to predict the cost of work. The reasons why engineers' estimates have so often been unreliable may be enumerated as follows:

1. Students of engineering are seldom trained in the art of cost estimating, but left to acquire that art haphazard after graduation.

2. Articles descriptive of engineering structures seldom contain an analysis of the unit costs.

3. A subsurface survey is frequently not made; and, as a consequence, unexpected materials are encountered in excavating.

4. A study of the sources of local materials, their suitability for the work, and their unit cost delivered, is often not made; and, as a result, specifications are frequently drawn that cannot be lived up to except by importing materials at great expense.

5. The cost of clearing, and draining the work is often underestimated, or ignored entirely.

6. The cost of temporary bracing, support, roadways and development expenses are frequently underestimated or omitted.

7. Delays due to bad weather, and delays incident to the shifting of plant from place to place are often not considered.

8. Interest and depreciation of plant, and the percentage for profits, are usually underestimated.

9. Inadequate allowance is made for superintendence and general expense.

10. The cost of inspection and engineering may be underestimated.

11. Legal expenses due to the abandonment of the work by a contractor, or due to suits brought by those who claim damages to life, limb or property, are generally not allowed for.

12. Changes in the alignment or in the design, made after contracts have been awarded, may result in large claims for extra compensation.

13. Omissions due to carelessness or ignorance of subordinates in the engineering staff may result in further claims for extras.

14. Rates of wages and prices of materials may rise; and, if the work is large, the work itself may be the cause of such increases.

15. When high wages are due to scarcity of men, an "independence" is bred in the workmen which decreases their efficiency.

16. A large number of competent foremen frequently can not be secured for a large work, resulting in decreased efficiency of workmen.

17. If an estimate is based upon previous contract prices there is grave danger of error, due to change in conditions, unbalanced bids, etc.

18. If unit prices are estimated before the specifications are drawn, the specification requirements may be made such as greatly to increase the cost of important items.

19. Limiting competition by the drawing of unfair, or indefinite specifications, is a common cause of high bidding prices. Severe interpretation of indefinite clauses often causes failure of contracting firms, and the history of such failures operates to limit subsequent competition, and raise prices.

20. Contractors may combine, especially where the work is let in very large contracts, and raise prices.

Indexing Contract Prices.—In order to fix a bidding price on the proposed work, if no actual records of similar work are available, it is customary to hunt up bidding prices on similar work, strike an

average, bid a little below the average—and trust to luck. To make this process less of a gamble, it is wise to secure back volumes of engineering periodicals, and make a scrap book using the pages of the journal that relate to contract prices. Then as the scrap book should be indexed, a word as to indexing may be of assistance. There should be heads corresponding to the items usually found in bidding sheets, as follows: Asphalt Pavement, Ballast, Bolts and Spikes, Brick Masonry, Brick Sewers, Brick Paving, Bridges, Castings, Catch-basins, Cement, Clearing and Grubbing, Concrete, Curbs, Earth Excavation, Embankment, Flagging, Flush-tanks, Gravel, Gutter, Hydrants, Iron, Lampposts, Lead, Macadam, Manholes, Masonry (stone only, and not brick or concrete), Piles, Pipe Sewers, Puddle, Railing, Riprap, Rock Excavation, Sidewalks, Sodding, Specials, Steel, Stone, Timber, Tracklaying, Valves, Water Pipe, etc. As far as possible select headings that denote the kind of material used in the structure; but where this cannot be done without confusion select the name of the structure as it ordinarily appears in bidding sheets. Do not, as a rule, use such headings as the following: Abutments, Filling, Dredged Material, Foundation, Vitrified Brick Paving, etc. An abutment often contains piling, concrete and cut stone masonry, and in using the index it may not occur to you to look under abutment when looking up prices on concrete.

Having decided upon headings, cut up a lot of paper strips about an inch wide and four inches long, and proceed to go through the printed pages to be indexed. When a bid on Concrete is found, write on one of these slips, "Concrete, pavement foundation, p. \$0." Throw the slips aside as the index entries are made; and, after a volume has been indexed, assort the slips alphabetically, and have a typewritten index copied from them. Simple as this method is, the inexperienced man is not likely to think of it, and failing to think of it he will look upon the job of indexing as being so great a task that in all probability no index will be made. Indexes published at the end of the year by the technical journals are, as a rule, of no value to the contractor; furthermore, the current issues of construction news should be indexed as fast as received. Especial care should be taken to index classes of work that are out of the ordinary, for whenever bids must be submitted on similar work no better guide than previous contract prices is apt to be found.

In recording bidding prices, it is well to record not only the lowest bid, but the average of all bids, stating the number of bidders.

In judging the reasonableness of a bidding price, it is of great assistance to know the experience of the bidder on the particular class of work in question. Hence a knowledge of the history of contractors is a decided aid.

Care should be taken to examine not merely a contractor's bid upon the one item that is under consideration, but his bidding prices on all the items, to judge whether or not he may have unbalanced his bid to conceal his judgment as to a fair price for each item.

Unbalanced Bids.—A bid is said to be unbalanced when too high a price is purposely bid upon one or more items, accompanied by an offsetting low price on one or more of the remaining items. Thus, if a fair bidding price for earth excavation is 25 cts. per cu. yd., and for rock, \$1.00 per cu. yd., the following forms an example of a bid that is balanced, and one that is unbalanced:

BALANCED BID.	
1,000 cu. yds. rock, at \$1.00.....	\$1,000
20,000 cu. yds. earth, at \$0.25.....	5,000
Total	\$6,000
UNBALANCED BID.	
1,000 cu. yds. rock, at \$2.00.....	\$2,000
20,000 cu. yds. earth, at \$0.20.....	4,000
Total	\$6,000

It will be seen that the total bid, \$6,000, is the same in both cases. In the second case, however, the \$2 bid on rock is altogether too high, and the 20-ct. bid on earth is too low, hence the bid is unbalanced. The objects of unbalancing bids may be three: (1) To secure an abnormally high profit on any item the yardage (or quantity) of which is likely to be increased after the contract has been awarded; (2) to secure a large profit on the items of work that must be done first, thus skimming the cream of the contract in the very beginning; (3) to conceal from engineers and from competitors what each item of work is actually worth.

To prevent the unbalancing of bids, engineers resort to various expedients, among which are the following: (1) Insertion of a clause in the "invitation to bidders" warning them that an unbalanced bid will cause the rejection of the bid, (2) requiring a lump-sum bid on the work, (3) publishing the engineer's schedule of items and an estimated price for each item, then requiring either (a) that each contractor shall bid a uniform percentage on all the items, or (b) that the contractor shall bid his own price on each item, no unit price being in excess of a certain percentage of the engineer's estimated unit price. The first of these two methods is called the "percentage method of bidding."

A fourth method of preventing unbalancing of bids on small items likely to be increased in quantity may be suggested. It would consist in naming a definite unit price that will be paid on each of the minor items, and leaving the contractor free to bid his own prices on the other items.

The greatest danger from an unbalanced bid lies in subsequent change of quantities. Suppose that in the above given example, actual work discloses that a far greater quantity of rock exists than the 1,000 cu. yds. given in the bidding sheet. Suppose the actual quantities in the final estimate are reversed, and that there are 20,000 cu. yds. of rock and 1,000 cu. yds. of earth. We then have these results:

BALANCED BID.	
20,000 cu. yds. rock, at \$1.00.....	\$20,000
1,000 cu. yds. earth, at \$0.25.....	250
Total	\$20,250

UNBALANCED BID.

20,000 cu. yds. rock, at \$2.00.....	\$40,000
1,000 cu. yds. earth, at \$0.20.....	200
Total	\$40,200

We see that if the unbalanced bid is accepted the work costs in the end almost twice as much as it would have cost had the balanced bid been accepted; yet the two bids were the same (\$40,000), according to the preliminary estimate.

It rarely happens that such an extreme case as this occurs in practice, although I have known several quite as bad. The principle, however, is best illustrated by an extreme example.

It is common practice among paving contractors in many cities to unbalance their bids for the sake of concealing their estimates of actual worth; as, for example, among asphalt paving companies. Bidding prices must, therefore, be looked upon with suspicion always, especially when used as guides for estimating.

An unbalanced bid is a two-edged sword. It may actually ruin the contractor who makes it, if it happens that he has erred and that the quantities on which he has bid too low are greatly increased, without a corresponding increase in the quantities on which he has bid high. Like all tricky practices, it is a dangerous one.

Surety Company Bonds.—It is becoming more and more the practice to require contractors to furnish the bonds of a surety company rather than the bonds of individuals for the faithful performance of the work. This is not only good public policy, but it is in the best interests of contractors themselves.

No man should put in jeopardy the property of his friends by asking them to go on his bonds for a contract. It matters not how sure he may be of himself and of his ability to execute the work at a profit, for he should bear in mind that a strike beyond his control may upset all calculations. Furthermore, a young contractor's own estimate of himself is apt to have an optimistic tint, to say the least. A surety company should be consulted, and it is well to go to such a company at first with only a small contract for which bondsmen are desired. Be prepared to give them in detail your experience and your financial resources, exaggerating neither; for, in case of subsequent failure, criminal proceedings may be brought against a man who has misrepresented his resources. If you have but little cash capital, frankly say so, but be prepared to show in detail how you propose doing the work with the funds available. Suppose you expect to have a \$5,400 earth work job to do; that you will have 12 weeks in which to do it, with two weeks margin for delays, etc.; and that payments of 85 per cent of the estimated value of the work done are to be made monthly, and you purpose beginning the work the middle of the month. You estimate the work to cost \$4,800, hence your weekly pay-roll will be \$400 if the work is done in 12 weeks. You are to pay your men every two weeks, hence you need only \$200 in cash to carry you until the first of the month, and as your contract calls for the monthly payment to be made the 10th day of the month, you can

count upon receiving \$765 (85% of one-sixth of \$5,400) in time to apply on the next pay roll. Your cash capital to start with is \$1,800, or practically twice as much cash as will carry the work, in case there are no unforeseen delays, and in case you have not underestimated its cost. If you are able to persuade the surety company's representative that your estimate of actual cost of the work is reliable there should be no difficulty in securing their agreement to act as your bondsmen.

Reasons Why Contract Work Is the Most Economic Method of Doing Public Work.—There are two methods of doing public work: (1) The day labor, or government force, method; and (2) the contract method.

By the day labor method the government (county, town, city, county, city or federal) hires the workmen and directs their work. The alleged advantages of this method are:

1. It saves the contractor's profits.
2. It insures better work.
3. It avoids lawsuits.
4. It permits beginning work without a complete survey or plans, and thus hastens completion.
5. It gives employment to local citizens and keeps all the money at home.

As to the first alleged advantage there is an evident fallacy, for the attitude is one of regarding a contractor's profit as something other than a recompense for his skilled services. A contractor's profit is his compensation for services—nothing else. Hence when a contractor is dispensed with there must be a substitution of some one in his place to render the service of manager. It is often urged that since a government must supervise a contractor, to see that he does his work properly, it is really paying twice for supervision of the workmen. This, again, is fallacious for two reasons: (1) Supervision that is merely inspection is far cheaper than supervision that consists in managing men; (2) there should be inspection of work done by government employees, and, in my opinion, there is need of a much more rigorous and expensive inspection of their work than of work done by contract. Government employees are prone to depart from plans and specifications, often for the sole purpose of partly concealing the otherwise high costs that would become evident to all. It is the verdict, too, of practically all unbiased and experienced engineers that day labor work does not deliver as good quality of product as contract work. This answers argument 2.

As to argument 3, avoidance of lawsuits, we have an advantage that is certainly well founded. It does, but the average cost of lawsuits is so small a fraction of the total cost of construction work done by contract as to be unworthy of serious consideration. Moreover lawsuits of this kind are almost invariably the result either of ambiguous specifications or of changing plans without equitable provision for payment arising from a change. The remedy for this condition is not an entire abandonment of the contract system. As well might a surgeon cut off a man's legs be-

cause he squints. Lawsuits are avoidable and are avoided by the best engineers, for they perfect their plans before securing bids, their specifications are so framed as to provide perfectly for any changes, and, finally, they never vitiate the written contract by departing one iota from its provisions.

There are many so called "contractors' lawyers" in our larger cities, who are little else than skilled thieves in league with other thieves who get contracts. That these "contractors' lawyers" are able to make money for themselves and their clients is due almost entirely to the fact that engineers do not adhere rigorously to the specifications. For if a lawyer can prove that the specifications have been violated, even to no great extent, no contract exists, and there is ground for recovery of profits *quantum meruit*—as much as he deserved. This leads to expert testimony as to profits reasonably to be expected, and this usually leads to a verdict that is a compromise between the two extremes of testimony. Railways and private corporations are not so frequently afflicted with lawsuits because their policy is not to award contracts to contractors of the kind above mentioned. Public officials should also be empowered to reject bids from contractors who have a record as litigants, as well as from contractors who can not show sufficient experience and financial resources. A remedy for an evil is always preferable to the wholesale execution of innocent and guilty alike.

As to the alleged advantage of beginning work before plans are complete, I deny it to be an advantage. Innumerable increases in estimated cost of public work are due to this very thing—beginning work in advance of the fullest study of conditions.

Finally, as to employment of local citizens, this is precisely what a contractor does. But—and mark well the difference—a contractor does not make his organization an old men's home or an asylum for the afflicted. The place for such is not on a piece of construction where they not only take up valuable room but act as the worst sort of examples for the young, ambitious and capable workmen.

Now let us consider briefly why the contract system of doing public work is advantageous:

1. The contractor is paid for his services by his profits, which is in strict accord with the fundamental law of management. (See page 74).

2. He is free to pay his superintendents according to his judgment of their worth, and all his employees according to the bonus system.

3. The contractor is a manager appointed by no official, elected by no "voice of the people" (which is more often the voice of ignorance than "the voice of God"), selected by no civil service examination. He has become a manager by virtue of the law of the survival of the fittest, as determined by strife for excellence. When this method of selection is to be improved upon by men, it may be well to consult the Deity who established it.

4. A "public servant" is a servant without a master. He may have a "boss" who acts as a proxy for the master, but the master,

the owner of the house—where is he? He is the butcher, the baker, the candlestick maker, a thousand, a million, or, maybe, a hundred million of him scattered across all the acres between two seas. He never is seen by the servant, nor felt, nor heard. This master who foots the bills of those who boost the bills never approaches an indolent superintendent and lays a hand upon his shoulder, nor says: See here, my man, unless this ends, you end this.

A contractor is a master, and the "servants" see and hear him. He is tangible; no vague rich Uncle Sam off somewhere, but a living personality on the job; not a genial personality, with lots of money to throw away, nor, on the other hand, a niggard. His aim is to pay proportionately to service rendered. He may be crude in his methods of doing so, but that at least is his method, which is infinitely more effective than any a government uses.

5. A contractor will experiment with labor saving devices. He will invent or he will encourage inventors by his aid. What government ever bred inventors in its service? A government superintendent may occasionally be so inventive by nature that not the most discouraging situations can stifle his ambition. But, as a rule, the government superintendent, having nothing to gain by successful application of an experimental machine or process, and having much to lose in case of failure—probably his job—adheres to the ancient motto: "It is better to be safe than sorry."

6. A contractor is not restricted to working his plant in one locality nor on one class of work. Hence he is frequently able to keep his plant and his men busy, in whole or in part, nearly all the time. In the Roads and Streets Section of this book the high cost of municipal plant and supervision expenses in New Orleans illustrates the point very well. During the season when the teams can not work on paving, they are idle. So are all the "salaried men." A contractor would have kept the teams at work hauling coal, or what not, for private concerns, if not in New Orleans, then elsewhere. But the municipality of New Orleans can not engage in private work, nor can it compete for public work in other municipalities.

7. A contractor can usually buy machines, materials and supplies more cheaply than any government. The absence of red tape delays in getting "action," the certainty that no "graft" must be paid to officials, and other factors operate in a contractor's favor, to say nothing of the fact that he is usually a more skilled purchaser.

8. A contractor almost invariably does his work at less expense for "overhead charges." On the Panama Canal, which is being built by government forces, the item of General Administration alone amounts to 18 per cent (in 1909) of the total cost! And when we consider that the total cost is fully double what it would cost a contractor, we have some idea of the meaning of this expense item.

The following extracts from a few editorials of mine on this general subject of the inefficiency of the day labor system of doing

government work will be found to contain the opinions of several eminent engineers:

Thomas Telford on the Day Labor System.*—One of the greatest civil engineers of all time, and the greatest of his own time, was Thomas Telford, the inventor of the telford road, engineer of hundreds of large bridges and builder of numerous canals and docks. He was the first president (1820) of the Institution of Civil Engineers.

Of all the monuments to Telford's hard, common sense and engineering skill none is greater than the "Rules for Repairing Roads," of which he is author. Rule 7 is entitled "Management of Labour," and reads as follows:

"All labor by day's wages ought, as far as possible, to be discontinued. The surveyors should make out specifications of every kind of work that is to be performed in a given time. This should be let to contractors, and the surveyors should take care to see it completed according to the specifications before it is paid for. Attention to this rule is most essential, as in many cases not less than two-thirds the money expended by day labor is usually wasted."

This rule was written a century ago, but time has not altered the nature of men nor the soundness of Telford's advice.

It is interesting in this connection to record Telford's success in the building of nearly 1,000 miles of roads in Scotland by contract. He let 120 contracts for this work, which extended over a period of 18 years, and in that time there was not a single lawsuit arising from any of these contracts. The work was done with an economy unheard of before Telford's time, and it was small wonder that his fame spread beyond the British Isles and led to his being called as consulting engineer on numerous engineering projects in Europe.

Telford had discovered—or, rather, rediscovered—the principle that workmen are far more efficient when in the employ of an individual or firm than when in the employ of a government, whether it be of county, town, city or state. His success as an engineer rested as much upon the application of this principle as upon his own genius as a designer of engineering structures.

The Opinions of Members of the Am. Soc. C. E. on the Day Labor System.†—In 1896 there appeared in the Transactions of the American Society of Civil Engineers a paper by Mr W. W. Follett on the "Cost of Sewer Construction, Denver, Colorado," in which were given data intended to prove the economy of day labor as compared with contract work. Doubtless the author was somewhat surprised to find not a single out and out supporter of his contention among all the members of the society who discussed his paper. On the other hand, the day labor system was unanimously condemned as a system to be applied in general to city work. Some of the

*Abstract from an editorial in *Engineering-Contracting*, May 5, 1907.

†Abstract of an editorial in *Engineering-Contracting*, June 2, 1906.

expressions of opinion are not without interest even now, coming as they do from men high in the profession. We quote:

Most cities began their public works by the day labor plan, but have been forced to adopt the contract system in self defense.—Foster Crowell, M. Am. Soc. C. E.

Contract work is more desirable and cheaper as a rule than work by the day.—Henry Goldmark, M. Am. Soc. C. E.

The writer's experience has been that sewer work generally costs a city less by contract than by day labor.—William B. Landreth, M. Am. Soc. C. E.

The tabulated results [given in Mr. Follett's article] as to cost do not show any striking gain over that of contract work in this case. This is one of a few instances where experiments of this kind have been successful. In probably seven cases out of ten the political tendencies of boards made up wholly of scheming politicians to give sinecures to political hangers on would have largely increased the cost of the work.—Andrew Rosewater, M. Am. Soc. C. E.

It is the writer's opinion that in most cities public work can be done to better advantage and at less cost by contract than by hired labor.—G. T. Nelles, M. Am. Soc. C. E.

We may add that Denver sewers, under discussion, were large brick sewers, and that each brick mason averaged 2,086 brick per 8 hour day, wages being \$4, which is far and away better than the usual output on day labor construction, but less than half what many contractors secure from their brick layers on sewer work.

It should also be pointed out that a strenuous effort was made by the city officials in this case to prove that day labor work would be the most economical for all sewer construction to be done in the future, and they were not only free to alter the specifications to attain their end, but naturally prompted to do so by self interest. In discussing this feature of the case, Mr. G. T. Nelles, M. Am. Soc. C. E., said.

"Another important factor in the cost of work done under proper supervision in this manner by cities is the fact that they do not enter into a binding contract with themselves to do the work in a fixed manner and under rigid specifications, as is the case when work is done by contract. On the contrary, they are always at liberty to make such change in methods or materials as experience may prove to be beneficial and economical to the work. Under the contract system it is rarely possible to make such changes, no matter how desirable they may be, without raising a cry of fraud or violating some of the terms of the contract. As a consequence whenever there is a choice of materials or methods under the contract system, the most expensive to the contractor is usually adopted."

We have italicized this last clause, for, unfortunately, it expresses the truth about the tendency on the part of many engineers to exact not merely the last pound of flesh, but to call for an avoirdupois pound, although the specifications might well be interpreted to refer to a Troy pound. This particular feature of contract work is perhaps the one most worthy of careful consideration by the engineer who aims to secure low bids from reliable firms.

There is but one way of accomplishing this end—namely: by preparing specifications with as great care as is given to the work of making the drawings. Sewer specifications are, as a rule, particularly weak in all that relates to the excavation of materials. Generally no soundings or test pits are made by the engineers and no classification of materials other than "earth" and "rock" is given. Not only is there no sub-surface survey, but there is not even a fair attempt in the specifications to provide for payment based upon what may actually be encountered. Practically all the "changes" to which Mr. Nelles refers would be unnecessary were proper sub-surface surveys made in advance of making the design and drawing the specifications.

Mr. Franklin Riffe, in *Trans. Am. Soc. C. E.*, Vol. 23 (1895), p. 596, says:

"Some years ago, while connected with railroad construction on the Pacific coast, the writer took pains to compare the cost of company work with the cost of contract work, and was somewhat surprised to discover that in nearly every case investigated the former exceeded the latter, the excess ranging from 25 to 100%. The recently constructed water works system of Portland, Oregon, furnishes an instructive example. * * * There was considerable work done by day labor, under the mistaken idea that this method would ensure the most satisfactory results, but the cost of the work largely exceeded the estimate."

The Metcalf and Eddy Report on the Day Labor System in Boston.—This report contains the results of the most exhaustive investigation into the relative economy of the day labor and the contract systems ever published and is convincing in its demonstration of the economy of the contract system. The report is one made in 1909 to the Boston Finance Commission, important extracts from which were published in *Engineering-Contracting*, Aug. 25, 1909, and in subsequent issues.

I regard this investigation as the forerunner of many more of its kind to be made by consulting engineers for finance commissions in other cities. In fact I look to see such finance commissions become permanent institutions, whose function it shall be to investigate every department of a municipality, with a view to determining unit costs. Thus will the public be put in possession of unbiased facts about the economic or uneconomic conduct of the business of government.

Mr. S. Whinery's Report on the Day Labor System in Boston.*—On pages 139 to 142 of his report to the Boston Finance Commission, Mr. Samuel Whinery says:

"(1) The claim that a municipality can execute its public work at an actual cost as low as the same work can be done by a contractor and thus save the profit that the contractor is entitled to make may be true as an abstract theory, but experience has shown that it is not generally true in practice. It has in many cases been

*Abstract from *Engineering-Contracting*, Dec. 29, 1909.

found true in isolated instances or for short periods of time, but when the practice has been continued for a considerable period it is almost invariably the case that direct work becomes more expensive than contract work. The reasons for this are not difficult to find. * * *

"(3) The claim that public work executed directly by the municipality is more certain to be of good quality than if done by contract is not well founded.

"It is a plausible proposition that municipal officers, having no personal financial interest in the results, will be actuated only by the desire to secure to the city the best quality of work, but experience has not shown it to be true. There are motives other than the mere saving of money that may, and as a rule do, influence city officials to cut down the cost of public work done under their direct supervision to the lowest figure, with possible detriment to the quality of the work done. * * *

"I have had good opportunity to observe in many cities the comparative quality of work done by the municipality direct and by contract, and I do not hesitate to say that, as a rule, the former is not usually superior to the latter.

"(3) The claim that it is either better or more economical for the municipality to purchase and furnish contractors the supplies required for public work is not supported by the facts. * * * many of which are obvious. Nor is it true as a rule that a better quality of supplies is secured when purchased by the city than when they are purchased by contractors under proper city specifications and subjected to proper inspection.

"(4) The claim sometimes made that by doing its work directly the municipality can so provide for the employment and control of labor as to benefit the city at large or its dependent citizens is fallacious in practice. When public work is to be done the necessary labor must be employed either by the city or by the contractor. For doing the same work the city can use no more labor than the contractor if the labor employed by each is equally efficient and equally well directed. If economical results are to be obtained, equal care and discrimination must be exercised in securing labor by the one as by the other. If it be said that the city may so manage the labor supply as to afford employment to indigent or inefficient laborers (whom no contractor would employ), who would otherwise have to be aided from the city treasury, it may be answered that the city can no more afford to employ that class of labor than the contractor, and that it is better and cheaper in the end to pension or otherwise care for the disabled or inefficient. Laborers belonging to these classes do not earn the wages paid them and a few of them scattered among strong and able workmen have a demoralizing effect upon the whole body by setting a low standard of accomplishment."

Experience With Day Labor on the Chicago Main Drainage Canal and at Panama.*—We now have the annual report of the Isthmian

**Engineering-Contracting*, Dec. 4, 1907.

Canal Commission, teeming with arguments in favor of continuing the day labor system. We quote:

"Omitting profits derived from subsistence and general stores and assuming the hours of labor the same in both cases, it stands to reason that the government, when warranted in making the necessary outlay for plant, can do work cheaper than a contractor, for no question of profits enters into the consideration."

It does not stand to reason that any government can do work as cheaply as a private party. Indeed, to make such a claim is going contrary both to reason and to experience upon which all reasoning is founded. The Isthmian Commission goes on to explain that on jobs of less magnitude than the Panama Canal it does pay to do the work by contract because in such cases the government has neither the plant nor the organization to do the work. In the case of Panama, however, the government has both. The grave fallacy in this argument lies in the assumption that it is economic to award contracts only because a suitable plant and an organized force of men can be secured quickly. These, it is true, are factors in favor of a contractor, but if they were the only factors, government contracting would have disappeared entirely fifty years ago. The government could well afford to own a sufficient plant to do all its construction work, and it would not take long to build up an organization to handle the plant. But plant and organization are merely the tools. Back of these tools must be a great incentive if work is to be done economically with this plant and this organization. Plant is nothing, organization is nothing, unless the brain that directs both is keenly bent upon saving every penny and entirely free to bring every resource to bear in effecting economy. It is this lack of sufficient incentive and of sufficient freedom of action that makes every government manager of work far inferior to the ordinary contractor. A government employee knows that his salary will go on regardless of the cost. Earth work may be costing the government 50 cts. a yard that would cost a contractor 30 cts., but Col. Goethals will draw his salary just the same, and so will every other employee clear down to the water boy. It is true that the chief engineer is actuated by the vague desire to make a "good record," but he is also well aware that his "record" can not be measured by any standard except the accomplishment of his two predecessors. The great desire to make wealth for himself is wholly absent. His brain is warmed to mild glow by the hope of being able to "make good," but there is no fire under his boiler that sets the steam valve popping. But granting him even a considerable amount of feverish desire to "make good," we find him bound head and foot, not by red tape but by the indifference of the vast majority of his employees. Why should his lieutenants sit up nights devising ways of reducing costs? Why should they go about jumping on the workers by day to sting them into action? The one act may break down health, they will tell you, and the other will surely make enemies of the men. What recompense will there be in these two losses? A share in the saving effected? No. A partnership in the business? No. An increase in salary? No, for

governments do not pay on the scale of what a man saves but upon the scale of what he spends. There are no bonuses, no special salaries for excellence in service, no partnerships—nothing but a mild hope that, if one does not die at the bottom, promotion to a higher rank will come some day as a result of death at the top. That is government work, and that is why a contractor's profit represents not additional cost to the government but merely a small fraction of the saving effected by a capable man driven by the fierce desire to make that saving as large as possible.

To illustrate what happens even to a contractor when this incentive is removed: On the Chicago Main Drainage Channel the firm of MacArthur Bros. was put in charge of excavating a section of glacial drift on a percentage basis. They furnished the plant and organization, but did not pay for the labor or supplies out of their own pockets. That was paid for by the Sanitary District, and MacArthur Bros. received 15% for use of plant and supervision. After a considerable amount of the earth had been excavated at a cost of \$6½ cts. per cubic yard, the Sanitary District gave up this day labor method in disgust. In a report on the work Chief Engineer Isham Randolph said: "This work may be regarded as an object lesson, clearly demonstrating from an economic standpoint the unwisdom of entering into any arrangement for carrying on the construction work of the Sanitary District by the direct employment of labor." (Hill's "Chicago Main Drainage Channel," page 33.)

We cite this case because the MacArthur Bros. are among the most competent contractors in the country, but even they could not combat the irresistible tendency of men to loaf the minute they know that a government is going to foot the bill and not a contractor.

Subletting Work and Purchasing Materials.—There is seldom a contract that does not involve subcontracting, even when the original contract specially prohibits subcontracting. Every purchase of materials for which cash is not paid at once is a subcontract. The term subcontracting, however, is commonly applied to the awarding of a contract by the contractor, the subcontractor being one who undertakes to furnish the labor and materials necessary to perform a given portion of the original contract.

Whether it be a purchase of materials or an award of a subcontract, there is one thing the contractor should never neglect to do and that is to attach a copy of the original specifications to his letter or to his subcontract. In his letter or his subcontract he should make definite reference to the attached specifications, stating that the materials or the work, or both, must conform to those specifications. Failure to do this may lead to serious misunderstandings and loss. For example, in ordering paving bricks from a manufacturer if the contractor fails to say that they must be subject to the inspection and tests of the engineer and if a large percentage of the bricks are "culled" (rejected), the manufacturer may refuse to supply other bricks to replace the "culla."

Another point that should never be overlooked is to have a written contract (an exchange of letters will suffice) for any mate-

risks or work involving a sum in excess of the sum specified in the Statute of Frauds of the state in which the material is purchased. In some states this sum is less than \$100 and in others it is \$500. Any verbal contract, no matter how many witnesses may be brought, is voidable if the sum involved is in excess of that prescribed in the Statute of Frauds. Once the materials ordered under verbal contract have been delivered and accepted, the verbal contract as to price becomes binding.

It is poor practice, in my judgment, to buy or rent anything by word of mouth, and foremen should be required to make all purchases by written order, keeping a carbon copy. All renting of tools or plant should be recorded in writing, by an exchange of letters or otherwise, so as to have the terms of the rental signed by both parties. I have had the verbal rental of a plow by a foreman cost me \$100 in lawyers' fees, etc.

A few suggestions regarding the subletting of work: Subletting should not be forbidden in the original contract. Repeated subletting of the same part of a job may be, and often is, pernicious in its effect upon the quality of the work. One subletting often results in lower cost of work, for a subcontractor who gives all his attention to a small job can usually get the workmen to do more work than a large contractor who has many things to attend to. The subcontractor is really a superintendent or foreman whose salary is paid in profits, and he has the best possible spur to secure the greatest possible economy.

The letting of several independent contracts for the different parts of a structure often leads to delays and claims for extras due to delays. One independent contractor may purposely delay another. All this is avoided by awarding the whole structure to one contractor, who can usually manage several subcontractors much better than several independent contractors can be managed by an engineer.

On the other hand, it is not an uncommon mistake to let a contract too great in size to secure active competition from several contracting firms. One of the best managed large pieces of public work was the Chicago Main Drainage Canal, contracts for which were let in sections of moderate size; with the result that there were many able competitors who named low prices.

Instructions to Superintendents and Foremen.—Some of the most successful contracting firms have sets of rules and instructions printed for the use of foremen and others. Certain of the "rules" are inflexible and must be obeyed; others are more in the nature of suggestions intended to guide the foreman in doing his work, handling his men, purchasing materials, and the like.

Gilbreth's "Field System" is a book of rules used by him in managing his contract work. His "Bricklaying System" is another such book.

I will give a list of instructions that is by no means exhaustive, but varied enough to give some hints as to the character of a set of instructions. Rules such as these can be mimeographed on

small sheets of paper and bound together with clips, so that they can be carried in the pocket for reference.

1. When a foreman arrives at a place where he is to have charge of work, he must notify the home office at once by postal card, giving the address of his boarding place and his office address.

2. A daily report must be sent to the home office on the blanks provided. If no work is being done, still a report must be sent in stating that fact and giving reasons for delays, etc.

3. Each foreman must keep a small diary in which to jot down the principal events of the day. Such a diary may be of great value in case of a law suit.

4. Each foreman must write all orders for materials, supplies, etc., in the book provided for the purpose, so that a carbon copy of every order will be kept. He must be careful to insert the day of the month. When a foreman wishes grading stakes or instructions from engineers in charge of work, let him send a written order to the engineer stating exactly what is wanted. This precaution may save misunderstandings and delays, and the carbon copy of such an order is often useful to check the memory. The sooner a foreman learns to be methodical in such small matters, the sooner will he be fitted to handle larger matters.

5. No superintendent, walking boss, engineer, time keeper, or other employe of this firm is permitted to give an order direct to any workman, except in case of great emergency. Not even a member of this firm is exempt from this rule. The foreman in direct charge of a gang of men is the only man permitted to instruct his men what to do. He is the officer in charge, and his superior officers must not intentionally or unintentionally degrade him in the eyes of his men by issuing orders over his head.

6. A foreman is not permitted to work with his men. He is employed to use his wits, not his hands. Occasionally he must instruct a man how to do his work, but he must teach the man and not attempt to take the man's place. It may take a foreman longer to teach a man than to do it himself; nevertheless it is cheaper in the long run to teach the man.

7. Do not use laborers to do the work of masons or carpenters, but provide a sufficient number of laborers to assist the skilled workmen. A 15-ct. man can lift as many pounds of wood or stone as a 50-ct. man. Exercise your wits in keeping each class of men busy at their particular class of work.

8. In rainy weather keep all steady pay men busy overhauling machines and tools, sharpening tools, branding tools, splicing ropes, etc.

9. Rush all percentage or force account work exactly as if it were part of the regular contract. The reputation of this firm is worth more money than can ever be made by "making work last."

10. Small jobs of extra work are usually taken on a basis of 35% profit on both materials and labor. This leaves but a small margin of profit after deducting general expenses. It is particularly desirable to work as many men as possible on a small job, so as to reduce the percentage of general expenses.

11. Keep the addresses of good workmen.

12. Do not be a "good fellow" with the men under you after working hours, or you will lose their respect. Remember the old adage, "Familiarity breeds contempt."

13. In case of any accident to a workman or to a spectator notify the home office at once by letter. If the accident is fatal, notify by telegraph or telephone. We are insured against such accidents, but by the terms of our policy we must notify the insurance company within 24 hours.

14. The best and cheapest insurance against accidents is care. Provide barricades, warning notices and red lights wherever an excavation is made. Even a small hole unprotected may cause the loss of a life, for which the courts may hold this firm responsible. When a street is closed by barricades, do not permit an outsider to enter even at his own risk, for should an accident occur a law suit is certain to follow regardless of the rights involved.

15. Accept no orders for extra work except in writing, and forward such orders at once to the home office.

16. Fill in your expense account blank every Saturday night and send to the home office.

17. When plans are received indorse your name upon them, with the day of the month and year. Write on blueprints with a red pencil.

18. Avoid all controversy with an engineer or inspector. A small quarrel often leads to a big loss. Notify the home office in case of unfair or unreasonable orders.

19. When a car arrives, record its number and character of contents. Remember that a demurrage is charged on all car freight held more than 72 hours; but on most roads demurrage is estimated by averaging. Thus, if one car is held 24 hours before unloading and another is held 96 hours, the average is $(24+96) \div 2$, or 60 hours.

20. Pile lumber with the boards slanting so that water will drain off. Lay as few boards or timbers directly on the ground as possible. See that the top layer of boards is turned over occasionally to prevent warping.

21. Insure all lumber and timber work against fire.

22. Count and measure all sticks of lumber to check the bill. To calculate the number of feet board measure (ft. B. M.) in a sawed stick of timber, multiply the width in inches by the thickness in inches, divide this product by 12, and multiply the quotient by the length of the stick in feet.

23. See that all shipments of materials are counted or measured and recorded.

24. For convenience in estimating the weight of materials remember the following:

Material.	Cu. ft. per ton of 2,000 lbs.
Water (62½ lbs. per cu. ft.)	32
Sand or gravel	26
Broken sandstone, limestone or granite	22
Broken trap-rock	20
Solid blocks of granite	12
Coal, broken	40

Green white oak is heavier than water and weighs more than 5 lbs. per ft. B. M. (there being 12 ft. B. M. per cu ft.). Green southern yellow pine weighs $4\frac{1}{2}$ lbs. per ft. B. M. Kiln dried oak weighs $3\frac{1}{2}$ lbs. per ft. B. M. and kiln dried yellow pine weighs 3 lbs. per ft. B. M. In any case, by floating a block of wood in water and measuring the total depth of the block and the submerged depth, the weight can be calculated by simple proportion, thus:

Depth of block submerged: Total depth of block:: The weight per cu. B. M.: 5.2. Thus if the block is 6 ins. deep and 4 ins. are submerged when it floats, we have:

$$4:6::x:5.2.$$

Whence we find that x is nearly $3\frac{1}{2}$ lbs. per ft. B. M.

Familiarize yourself with other rules useful in computing weights, etc.

25. On short hauls where dump wagons are not available provide extra wagons which can be loaded while the full wagons are going to the dump and returning. Extra wagons can usually be rented, and in some cases it will pay to buy them, for the lost team time soon eats up the price of a wagon. Extra wagons are especially useful where a small gang of men is unloading brick, stone or timber from a car onto the wagon. When a team comes up with an empty wagon, unhitch from the empty, hitch to the full wagon, and with a tall rope pull the empty wagon up to place as the full wagon moves ahead.

26. In erecting a derrick or pile driver remember that a gin pole or mast can often be used to advantage. Gin poles are not used as often as they should be for this kind of work.

27. In erecting a trestle for falsework, frame and bolt the bents together on the ground, then up-end them.

28. Use round timber for legs of temporary trestles, for trench braces, and wherever struts are needed. Round timber can usually be bought for much less money than sawed stuff.

29. In buying brick consider the size of each brick, bricks vary greatly in size. Large bricks are worth more per M than small ones. If $2\frac{1}{4}\times 8$ -in. bricks are worth \$6.50 per M, every $\frac{1}{8}$ in. increase in the length adds 10 cts. per M to the value, and every increase of $\frac{1}{8}$ in. in thickness adds 25 cts. per M.

30. In buying cement, consider the size of the barrel and the amount of cement paste that can be made with a barrel. There is a great variation in the product of different factories.

31. Buy cement in wooden barrels for use on small jobs that are liable to lag. Buy cement in cloth bags for most work. Pack the bags in bundles of 50, and ship to factory. Cement improves with age up to a certain point, if the air is not too damp. Use the oldest cement first.

32. Dynamite must never be thawed in any way except with a hot water thawer of the kind furnished by this firm. Never thaw in front of a fire, or on a hot stone removed from a fire, or by piling sticks on a boiler, or in an oven. We know of fatal accidents due to each of these methods. There may be safe methods

other than the one above ordered, but we can not afford to experiment where lives are at stake.

33. Never store dynamite, or acid, or gasoline in a tool box. The dynamite may be exploded; the acid vapors will eat into ropes and rot them; the gasoline vapors may explode or spilled gasoline may result in a fire. Use sand to put out a gasoline fire. Hemp rope is weakened not only by acid vapors, but by saturation with oil. All rope should be kept dry.

34. In using steam engines, steam drills and derricks, the following precautions should be observed:

Daub grease over all bright parts before storing, also in wet weather. Oil the derricks, crushers, wire ropes, and all movable parts of machines every day. Cheap black grease is usually daubed on wire ropes; but where the ropes are moving over sheaves almost continuously, provide an oil drip cup to feed oil, drop by drop, onto the moving rope.

Do not permit men to wash their hands in the water barrel or tank that supplies water to a steam boiler, for the grease from their hands will cause "priming."

Boiler flues are frequently "burned" because water is allowed to get too low in the boiler. Aside from the danger of a boiler explosion in such cases, there is the certain cost of repairs. See that the steam cocks are blown off several times daily, and do not rely upon the water glass.

A lazy or ignorant fireman will pile on coal and then rest until it has burned low. See to it that a thin bed of fuel is kept steadily burning. On large boilers use an automatic pressure recording gage to make the firemen attend to their business properly. It will not only save coal, but result in greater output of engines and steam drills.

Cylinders of engines and steam drills are frequently cracked in cold weather by suddenly letting in steam. To avoid this open drip cocks and cocks on steam chest and blow in steam for a few minutes to warm up the cylinder before starting the machine. A broken cylinder may delay work for a week.

Do not let a friction clutch get wet, for it may slip if it does.

Lower the boom of each derrick at night, so that it can not be dropped by some one for fun or for spite. Lay down short logs at intervals to keep the hoisting rope clear of the ground.

The foregoing will serve as examples of instructions and hints issued by a contractor. As they stand they possess the disadvantage of not being classified into instructions that must be obeyed and hints that may be followed.

Each contracting firm will have certain classes of work in which it specializes, and will find it advisable to prepare mimeographed or printed instructions not only of a general nature but of a special nature. Thus a firm engaged in building construction may give sketches of scaffolding and instructions as to its erection. A firm engaged in bridge building may prepare a set of rules to guide the foremen in coffer damming and in false work building.

System is fast taking the place of the hit or miss style of direct-

ing work. A well prepared set of instructions to foremen is an essential part of any complete system of management.

The Ten Laws of Management.*—The managing of industrial enterprises, such as construction work in the field, is still an art, and there are few who realize that it can be reduced to a truly scientific basis. Nevertheless there are certain underlying principles of effective management of men which may be expressed in the form of laws. Application of these laws leads invariably to a greater output on the part of workmen, and this invariability of result proves the scientific basis of the laws. The most important of them can be grouped under ten general headings, which are as follows:

1. The law of subdivision of duties.
2. The law of educational supervision.
3. The law of coordination.
4. The law of standard performance based on motion timing.
5. The law of divorce of planning from performance.
6. The law of regular unit cost reports.
7. The law of reward increasing with increased performance.
8. The law of prompt reward.
9. The law of competition.
10. The law of managerial dignity.

Below are given the main characteristics of each:

1. **The Law of Sub-Division of Duties.**—Men are gifted with faculties and muscles that differ extremely. One man will excel at running a rock drill, another is better at lifting loads, a third is clever in the application of arithmetic, a fourth is a born teacher—and so through the gamut of human occupation. Moreover, practice serves to accentuate these inborn differences. It is clear, therefore, that the fewer duties any one man has to perform, the easier it is to find men who can do the task well. But give a man many duties to perform and he is almost certain to do at least one of them poorly, if, indeed, all are not miserably attended to. Hence the following law of management: *So organize the work as to give each man a minimum number of duties to perform.*

This law needs little emphasizing as to its general truth, but it is nevertheless ignored frequently by those who have not applied a scientific treatment to management. Thus a foreman is often charged with a multitude of duties. He is expected, for example, to watch the workmen and spur them to action when slothful, to teach his men how to do their work in a more economic fashion, to discover and remedy defects in the machines and tools employed, to plan the arrival of materials at the proper time and in the proper amount, to keep records of daily performance, etc., etc.

Mr. Fred W. Taylor was the first, we believe, to urge the subdivision of the duties of foremen and to have what he calls "functional foremen." One foreman, for example, is the machinery and tool foreman. It is his sole duty to study the work done by machines and tools, to effect improvements, to reduce delays, and to supervise repairs.

*These ten laws of management were first published in "Cost Keeping and Management Engineering," by Gillette and Dana.

Another foreman is the gang foreman. His function is to organize the gangs, to direct their operation, and to instruct them in the performance of their work.

A material foreman is employed on large jobs. His function is to confer with other foremen and ascertain what materials, machines and supplies will be needed. He orders the materials, arranges for their shipment, and follows up the manufacturing and railway companies to secure prompt delivery. If necessary, he sends men to the factory, to the stone quarry, or to the freight yard to see to it that deliveries are made with dispatch. Such a man is often invaluable, for upon him may depend the entire progress of the work.

According to the magnitude of the contract there may be different kinds of foremen, all coming in contact with the same men perhaps, but all performing different functions. Such an organization as this differs radically from a military organization, wherein each man reports to only one superior officer on all matters.

Most industrial organizations today resemble military organizations, with their generals and intermediate officers, down to corporals, each man reporting to but one man higher in rank. There is little doubt that the present tendency in industrial organizations is to abandon the military system to a very large extent, and for the following reasons:

A soldier has certain duties to perform, few in number and simple in kind. Hence the man directly in command can control the actions of his subordinates easily and effectively. Control moreover should come invariably from the same officer, to avoid any possibility of disastrous confusion and to insure the instant action of a body of men as one single mass. On the other hand, industrial operations do not possess the same simplicity, particularly where men are using machines, nor is there the necessity of action in mass. The military organization, therefore, should be modified to suit the conditions; and one of these modifications is the introduction of two or more foremen in charge of certain functions or duties of the same men or groups of men.

On contract work it is often impossible to subdivide the duties of men to as great an extent as can be done in large manufacturing establishments. The smaller the contract, the less the subdivision of duties possible. In such cases an approach to the ideal system of subdivision is secured not by employing different men for different purposes but by a systematic assignment of duties to the same men to be performed at specified hours of the day or days of the week. Thus a small gang of carpenters is engaged in building forms for concrete, in repairing wooden dump cars, and in framing and erecting trestle work. By timing the men and by planning their work upon the timing records and the requirements of the work this carpenter gang can be assigned certain hours or days for each class of work. Thus is avoided the intermittent and uncertain shifting of the gang from one class of work to another, involving not only a loss of time in frequent shifting but a loss of interest in work that is done piecemeal. Moreover a methodical

change of occupation permits a methodical record of the number of units of each class of work performed, and thus leads to the use of the bonus system of payment.

2. **The Law of Educational Supervision.**—It is not alone sufficient to give instructions to workmen and foremen from time to time by word of mouth, but the gist of all important instructions should be reduced to written or printed form. Among contractors the pioneer observer of this law is Mr. Frank B. Gilbreth, whose "Field System" is a 200-page book of rules for his superintendents, foremen and others to follow. His "Bricklaying System" is another set of rules for the guidance of his brick masons and foremen.

Among manufacturers there are many examples of those who have prepared more or less elaborate sets of rules to be followed, but the most interesting of these compilations that have come to our attention is the one furnished to its salesmen by the National Cash Register Co. In this book are gathered a vast number of useful hints and practical suggestions and arguments to be used in selling National cash registers. Each possible objection that a prospective purchaser may raise is met with one or more specific answers. This company not only provides its salesmen with a text book but has a school for training salesmen. At regular intervals all the salesmen meet together and discuss their respective methods of selling cash registers. Any new suggestions that are good become subsequently a part of the book of instructions. Thus the combined wisdom of hundreds of salesmen is preserved and delivered to every salesman that the company employs. This plan is followed also by many of the life insurance companies. Railway companies have long made it their practice to furnish their civil engineers with printed sets of rules for railway location, as exemplified in McHenry's "Railway Location." All these are forms of educational supervision, and some are very elaborate. The small contractor need not necessarily have a printed book of rules of his own making, but he can supplement some such book of rules and hints by a typewritten or mimeographed set of sheets containing the most important of his own instructions. In this manner the repetition of a costly blunder by a foreman or workman can be avoided by a special rule or hint, while a labor saving "trick" can be passed on to other men in the contractor's employ.

In developing a system of educational supervision the greatest assistance can be obtained from articles in engineering and contracting periodicals, for there will be frequently recorded labor saving methods well worthy of trial by other contractors. In a long article it may be only a small hint that is worthy of being abstracted and placed among the hints for foremen.

In preparing a set of rules and hints, take pains to distinguish sharply between what is a rule always to be followed and what is a hint to be followed optionally. It is well to have a set of rules, each with its specific number, and a separate set of hints, also numbered.

The second law of management is briefly this:

Secure uniformity of procedure on the part of employees by providing written or printed rules, supplemented by educational suggestions or hints to guide them in their work.

3. The Law of Co-ordination.— *So schedule the performance of each gang of men that they will work in perfect coordination with other gangs, either adjacent or remote.*

Perfect coordination involves the working of each man to his capacity all the time. This necessitates not only the organization of gangs of just the right size but the prompt arrival of standard supplies and materials, and freedom from breakdowns of plant.

An examination of almost any piece of construction work in progress will disclose the fact that most of the men spend a considerable portion of their time waiting either for somebody else to do something or for materials to arrive, before they can proceed. The cause is improper coordination of the work. One gang may have too many men and therefore may be able to work considerably faster than another, and be continually catching up with it. They will then adopt a slower pace, keep seemingly busy, and manage to kill a large percentage of their working time. These delays are chargeable to lack of coordination, although a careless inspection of the work may seem to indicate that everything is going smoothly. A job can look smooth and at the same time be so badly co-ordinated as to be uneconomical.

The necessary adjuncts to proper coordination of work are briefly as follows:

1. A carefully drawn schedule of performance.
2. Regular arrival of material and supplies.
3. Prompt and proper repairs to equipment.
4. The proper quality of supplies.

The best method that has so far been devised for making things happen on time is first to prepare a time table, and then to live up to it as far as the interruptions of the weather and the limitations of human nature will permit. To prepare a time table properly it is necessary to know how fast work can be done under the conditions which are to govern it. At the best there will be a considerable variation to be accounted for by ignorance on the part of the planning department on the one hand and by the interference of the elements on the other. A form of chart, made on tracing cloth, with various symbols to indicate the kinds of work to be done, has been found very useful. As the work progresses the performance can be checked off on the chart, and thus indicate whether the work is proceeding on time. Where the work is such as that of building construction and there is but little storage capacity for materials, it is best to have the chart prepared a considerable time in advance so that materials will arrive when they are needed and yet not so much in advance of the proper time as to require large storage capacity at the site of the work.

4. The Law of Standard Performance Based on Motion Timing.—*Nearly every operation performed by a workman involves several*

motions, although at first sight it may often seem that there is but one.

Mr. Frank B. Gilbreth has coined the term "motion study" to denote his method of observing the number and kind of motions made by a man—a brick layer, for example—in performing a given operation. His plan is to analyze the motions, assigning a name to each motion. His next step is to endeavor so to arrange the supply of materials, the position of tools, etc., as to reduce the number of motions and the distance of each motion to a minimum.

Mr. Fred W. Taylor was the first, we believe, to adopt the practice of invariably studying each motion by the aid of a stop-watch. A large number of stop-watch observations not only give the average time of a motion, but, what is of far greater importance, they indicate what the minimum time for each motion may reasonably be expected to be. It then follows that the sum of these minimum times for the different motions represents a standard time of accomplishment of the entire process. Hence our law of motion timing:

In the performance of every process the sum of the minimum times observed for each motion gives a standard of performance possible of attainment under sufficient incentive.

Mr. Harrington Emerson calls this standard of excellence 100%, and has developed the plan of rating all actual performances in percentages. Thus if the standard time for drilling a 10-ft. hole in a certain rock were 60 minutes and, if the actual time were 90 minutes, this performance would be rated at $60 \div 90 = 66.67\%$.

In establishing a standard time of performance, the first step is to ascertain the unit times upon the work as ordinarily performed. The next step is by study of the time elements and the local conditions to eliminate as many motions as possible and to reduce the time of others, either by shortening the path of motion or by accelerating the velocity of the motion.

To illustrate by an example we give the following time study, which was made by Mr. Dana some time ago on some cableway work. Since this was done the Lidgerwood Mfg. Co. has completely redesigned its cableway engine and fall rope carriers and has introduced new features in control (notably in the Gatun cableways in Panama). Therefore, while the data are correct as history, they must not be taken as indicating the limit of present possibility. A considerable number of studies was made, but one only is given for purposes of illustration. (See Table VII, p. 70.)

The first column gives the abbreviations of the processes, distances, etc.; the second gives the number of recorded observations on each process; the third gives the minimum observed time in seconds for each process in that table; the fourth gives the average; the fifth gives the maximum time; the sixth gives the minimum of all the observed times for each process. While this is by no means the shortest possible time in which the process could be accomplished, it is the shortest one observed, and has here been taken to represent standard (100%) efficiency. By dividing the standard time by the average for each process the average efficiency as observed is obtained. This is shown in the seventh column.

As a result of this time study, it was possible to make an estimate of the probable increase in efficiency that could be obtained by rebalancing the engines. A further improvement was discovered in the method used in signaling to the operator, and an estimate of the saving to be obtained in this manner was made. A further improvement in regard to the position of the operator was discovered. A collateral improvement was perceived in the line of altering the design of the towers, so that the cost per unit of handling materials could be reduced, and further suggestions of a confidential nature, which we are not at liberty to discuss here, were made.

5. *The Law of Divorce of Planning From Performance.*—As a corollary to the law of the subdivision of duties, we have the law of divorce of planning from performance, first formulated by Mr. Taylor.

According to the old style method of management, each foreman is left largely to his own resources in planning methods, in addition to his other functions. This multiplicity of duties can be properly performed only by a foreman possessed of a multiplicity of talents. Since few men can comply with such a specification for brains, it follows that good foremen of the old style are rare indeed. The modern system of management consists, as far as possible, in taking away from the foremen the function of planning the work, and

in providing a department to do the planning. Under planning we include inventing, that is, the improvement of existing methods and machines.

A common error in management is the assumption that the man on the job in direct charge of the work is the man best fitted to plan and improve. Nothing is further from the truth. Rare, indeed, is the man possessed of a trained inventive faculty, and it requires such a faculty not only to develop new methods and machines but to plan the use of any machine with greatest economy. Nearly every piece of contract work presents new conditions, and this solving of new economic problems is beyond the power of any but the trained and skilled economist. But even where the problems remain identical, the necessity of a divorce of planning from performance exists, as we shall indicate.

The brain is an organ that requires frequent exercise in doing the same thing before it becomes proficient enough not to suffer great fatigue. Thus, the man who is learning to ride a bicycle finds that half an hour's lesson has tired him more than ten hours' work at his accustomed occupation. Attempting to do something new is wearisome beyond measure, except to the mind whose training has been in solving new problems. Hence the ordinary man finds much fatigue and little pleasure in attempting to do his work in a fashion that differs at all from that to which he has long been accustomed. The mental inertia that resists a change in methods of performing work is almost beyond comprehension, and it is found not only in the lowest type of workman but in the highest.

Repetition develops skill, and skill gives pleasure. To a strong man used to his work there is actual pleasure in mowing hay, as Tolstol has admirably pictured in one of his novels. Conversely, fatigue merges into pain and is repulsive.

In addition to these fundamental reasons why men adhere to precedent in their performance, there is the fear of ridicule in case of failure to succeed in any new attempt. The child learns to speak a foreign language more rapidly than an adult not only because of a more "flexible tongue" but because it does not fear laughter at its blunders. Partial failure is expected of the child, and it is not ridiculed. But an adult seems witless if he does not immediately learn the new word and its pronunciation; hence the laughter. So it is with every new performance. Furthermore, a serious mistake may lead to the loss of a position, thus adding another reason for sticking to the "good old way."

Finally, there is no method so fruitful in effecting improvements in methods and machines as a study of the time required to perform each movement or operation. A workman or foreman rarely studies his own work in this manner. Hence his experience, upon which he is wont to brag, is like the experience of the swallow building its nest—an unchanging adherence to precedent, regardless of possibilities of improvement.

It is a significant fact that nearly all the great inventions have been the product of brains divorced from the actual performance

of the machines that they have invented. Eli Whitney, inventor of the cotton gin, was a lawyer, and not even a southern planter. Smiles' "Self Help" is a volume full of instances of important inventions made by men remotely, if at all, connected with the class of industry in which their machines are used. Nothing, therefore, is more ridiculously illogical than the common belief that the "men behind the gun" are either capable of being the inventors of the gun or the ones most likely to improve it. Yet it is this illogical belief that prevents railway companies, manufacturers and contractors from making hundreds of radical economic improvements.

Summing up, we have this law:

For maximum economy of performance, the planning of methods of doing work should be the sole function of a manager who is not a workman himself nor in direct charge of the workmen.

6. The Law of Regular Unit Cost Reports.—Having planned a method of performance, it becomes necessary to secure daily, weekly and monthly reports of such completeness that a manager can tell, almost at a glance, what the actual and relative performances are. This systematic reporting is more fully treated under the head of cost keeping. The success of nearly all large corporations, such as the Standard Oil Company, is due, in large measure, to a system of regular reports that put the various managers in constant touch with the performance of the men under them. Reports to be of much value must come at short, regular intervals, must be in the same form, and must show quantitative results that admit of instant comparison with previous reports. To permit comparison there must be either similarity of conditions, or there must be a reduction to units that are themselves practically identical. For example, a weekly record of the number of yards of earth excavated and hauled at a given unit cost is usually of little or no value to the manager unless there is a further subdivision of units of cost. The cost of loading per cubic yard should be segregated from the cost of hauling, so that the cost of hauling can itself be expressed in the unit of the yard-mile or ton-mile hauled.

The law of regular unit cost reports may be formulated as follows. *Report all costs in terms of units of such character that comparison becomes possible even under changing conditions, and let these reports be made daily if possible, weekly in any event, and with a monthly summary.*

It is in the adherence to the terms of this law that managers of contract work in the field will find their greatest difficulty. First, there is the difficulty of selecting suitable units upon which to report costs. In pavement work, the square yard is a convenient unit and the number of units is easily measured daily. But in reinforced concrete building construction, there is needed not merely the cubic foot or cubic yard unit, but many others, some of which are not easily ascertained every day.

For example, the pound of steel reinforcement is one unit upon which reports should be made, for the number of pounds of steel per cubic yard of concrete differs widely. The thousand feet board

measure in the forms is another necessary unit, and the square foot of concrete area covered by the forms is still another. Yet these and other units must be used to admit of any rational comparison of performance from day to day and week to week.

Furthermore, such units must be properly selected for the still more important purpose of paying the workmen according to any bonus system. In another chapter we discuss this problem of selecting units of measurement at considerable length, for upon such selection depends the success of contract work under the modern method of management.

7. **The Law of Reward Increasing With Increased Performance.**—All payments for work should be proportionate to the work done. This is the fundamental law of economic production. When this law is ignored—and it is partly ignored to-day on practically every class of work—the producer ceases to take keen interest in his work. Under the common wage system of payment, one brick mason receives as much as another, regardless of skill and energy. Individual incentive is lacking, save as it is supplied by fear of discharge. When laborers, working under the wage system, are put at the task of shoveling earth into a wagon, each man seeks to do as little as his neighbor, and the slowest becomes the pacemaker for the rest. Such ambition as any individual may possess is stifled by the knowledge that his increased output will never be known by his employer, and consequently never rewarded. Moreover, an ambitious man in such a gang is chided by his fellows who warn him not to set a "bad example" by working himself out of a job.

The wage system is responsible in the first place for lack of sufficient incentive to good performance, but its vicious effects have been greatly augmented by the stupid actions of many labor unions, such as the restriction of daily output, the limiting of the number of apprentices, the demanding of wages that have no relation whatever to the output of individuals, the refusal to work under foremen who are not also members of the union, the refusal to do any sort of work except that prescribed by the union, and the like. In the long run, all such restriction of output, whether due to the lack of sufficient incentive, or to the rules of labor unions, or to the customs of a country crystallized into caste such as exists in India, lead to a reward commensurate with the output. Summing up: The wage received becomes ultimately proportionate to the output. The high wages prevalent in America are due neither to labor unions, as some profess to suppose, nor to abundance of natural resources, but to the fact that in America labor unions have not thus far greatly restricted the output of individuals except in a few trades, and more particularly to the fact that they have not opposed the introduction of labor saving machinery. In addition, American managers are far in advance of all others in their recognition of the fundamental law of management—namely, that the reward should be proportionate to the performance. Hampered though they have been by the wage system, American managers have been liberal in their policy of payments for work performed. In recognition of his share in the greater output of earth excavation, the steam

shovel enginemen in the United States receives \$125.00 to \$175.00 a month.

Within the past decade still further strides have been made by American managers toward a more effective recognition of this fundamental law of proportionate rewards. Various systems of payment, known as the bonus system, the differential piece rate system, and the like, have come into more general use, and even the old piece rate system has received a new lease of life, all tending wonderfully to stimulate the energy and wits of workmen, because they are in accord with the law of proportionate reward.

8. *The Law of Prompt Reward.*—Any reward or punishment is that is remote in the time of its application has a relatively faint influence in determining the average man's conduct. To be most effective, the reward or punishment must follow swiftly upon the act. Hence a managerial policy that may be otherwise good is likely to fail if there is not a prompt reward for excellence. Most profit-sharing systems have failed, principally because of failure to recognize the necessity of prompt reward, as well as because of failure to recognize the necessity of individual incentive.

The lower the scale of intelligence, the more prompt should be the reward. A common laborer should receive at least a statement of what he has earned every day. If, in the morning, he receives a card stating that he earned \$2.10 the previous day, he will go at his task with a vim, hoping to do better. But if he does not know what he has earned until the end of a week, his imagination is not apt to be vivid enough to spur him to do his best.

A daily or weekly statement of earnings, followed by prompt payment, is a stimulus essential to securing the maximum output of workmen.

9. *The Law of Competition.*—The pleasure of a competitive game lies in conquering an opponent, and this follows logically from the fact that competitive games are an evolution from the primitive chase or battle. Work conducted as a competition becomes a game, and thus stimulates those engaged not only to strive with great energy but to derive keen pleasure from the contest. The business man who continues to pile up millions, long after his wealth is sufficient to satisfy every possible want, does so from pure joy in the contest to excel others engaged in the same business. He is following the law of competitive work.

By pitting one gang of workmen against another gang, the spirit of contest is easily aroused. But it is impossible to maintain this spirit indefinitely without following the seventh law of management of men—namely, by making the reward proportionate to the performance. When, however, this seventh law of management is observed, an added spirit is given to men by pitting one gang against another. Thus, in laying concrete by hand for a pavement, the best method is to have two distinct gangs working side by side, each gang concreting from the center of the street to the curb. When this is done under a bonus system of payment, the output is astonishing.

Where competing workmen cannot see one another's output, a bul-

letin board should be used, whereon the number of units of work performed by each man or each gang of men should be posted.

Convert work into a competitive game by organizing competing gangs of men and by posting their performance.

10. **The Law of Managerial Dignity.**—That there should be anything like caste among managers seems, at first, repulsive to democratic principles of government, whether the government be political or industrial. Nevertheless, a study of the personality of the most successful managers usually discloses a characteristic of firmness coupled with a sort of austere dignity. The best manager is never "one of the boys."

Managerial control reaches its acme of excellence in the army, and there we find class distinctions most scrupulously observed. The officers do not "mess" with the men, nor do they form close friendships with the soldiers in the ranks.

Familiarity breeds contempt, or it breeds at least a feeling that the great man is not so great after all. All managers are under the constant fire of criticism of their subordinates, whether they realize it or not. The best shield that a manager can wear is distance. His little foibles—and all men have them—may thus be kept concealed. It is essential that they be concealed, for men of less mental endowment, will always seize upon the little defects of greater men's character or attainment as evidence of lack of any real superiority. The eye of criticism is a microscope for human frailties. Being a microscope, it is wise to keep beyond its range, so that the whole character may be viewed by the naked eye in its true perspective.

Discipline in an industrial army is as essential as in a military organization, and it is best secured by military methods. This involves (1) The social separation of the officers from the men; and (2) a sequence of responsibility from the man in the ranks to the highest officer.

For every act on the work every man should be responsible to some particular man higher in authority. There should never be any doubt as to whom a man is responsible; but it does not follow that a man should be responsible to only one person, except for certain acts. As we have previously shown, an industrial organization may have several classes of foremen, to each of whom each workman is responsible for certain acts. What we now emphasize is the importance of not dividing the responsibility for any particular act. A contractor, for example, should rarely give any orders to a workman. All orders should come through the proper foreman. To do otherwise results not only in reducing the workman's respect for the foreman, but it frequently angers the foreman, who feels that he has lost dignity in the eyes of the workmen.

It is often wise to change foremen from one gang to another, in order to preserve the class distinction between foremen and men. As foremen become acquainted with the men, they generally want to be regarded as good fellows, and will then permit infractions of rules and a general decrease in activity. Who has not noticed that

short jobs usually move with a "snap" that is not always characteristic of longer jobs?

We may sum up thus:

Discipline is best secured by managerial dignity, and dignity is best preserved by social separation of managers from subordinates and by an invariable sequence of responsibility.

Measuring the Output of Workmen.*—Before men can be paid according to their performance it obviously is necessary to devise methods of measuring the number of units of work done, but it is not always so obvious what units to select nor how to measure them readily after the selection of units has been made. Indeed, this difficulty accounts in large part for the slowness with which piece rate and bonus systems have been adopted.

Subdivision of Units into Other Units. In engineering construction the cubic yard is a very common unit upon which contract prices are based, but the cubic yard itself is frequently a very uncertain unit of performance, for it is a composite of other units. Thus, in rock excavation there are several distinct operations involved, which may be enumerated as follows:

1. Drilling.
2. Charging and firing (or blasting).
3. Breaking large chunks to suitable sizes.
4. Loading into cars, carts, skips, or the like.
5. Transporting.
6. Dumping.

The important item of drilling depends largely upon the spacing of the drill holes, which varies in different kinds of rock, and in different kinds of excavation, trenches and tunnels requiring close spacing. Clearly, then, the lineal foot of drill hole is a unit of work that must be adopted by the rock contractor in measuring the output of his drillers, and not the cubic yard.

Transportation is largely a function of distance, hence the unit of transportation cost should be the ton (or yard) carried 100 ft. or 1 mile, and not the cubic yard without the factor of distance.

Our first rule to be applied in seeking units that truly express the amount of work done is as follows: *Divide the contract price units into sub-units, selecting the "foot-pound" of work as the sub-unit wherever possible.*

A foot-pound is the unit of work used in theoretical and applied mechanics. It is the amount of work required to lift 1 pound a height of 1 foot. All forms of work are capable theoretically of being expressed in foot-pounds, but it is often very difficult to do so in practice. For example, it is not an easy matter to ascertain how many foot-pounds of work a man performs in shoveling earth into a wagon, for there is not only the number of foot-pounds involved in lifting the earth but in pushing the shovel into the earth,

*The following pages relating to the measurement of the output of workmen have been abstracted from "Cost Keeping and Management Engineering," by Gillette and Dana.

in lifting the shovel, in lifting the upper part of his own body, and in overcoming the inertia of earth, shovel and body. However, the theoretical ideal unit is the foot-pound, and, in selecting the actual unit to be used, the effort should be made to secure a unit that is as closely equivalent to the foot-pound as possible. Thus, in drilling, there are certain units of work done by the drill in pulverizing the rock in the drill hole, and this work is quite closely represented by the number of lineal feet of drill hole in any given kind of rock. Hence the most practical unit of work in drilling is the foot of hole drilled.

The second point to consider in selecting suitable units of work is the different processes involved. Each process on field contract work usually involves a different class of men. In rock excavation the six items above given usually involve six separate gangs of men. Although all contribute their part to the final contract unit upon which payment is received—the cubic yard—yet the work of each may be, and usually is, better measured in terms of some other unit. We already have seen that the lineal foot of drill hole—and not the cubic yard—is the unit to select for the drilling gang. The pound of explosive charged in the drill holes is a good unit by which to measure the work done by the blasting gang. The cubic yard of rock usually is the only practical unit of breaking large rock chunks. So, too, the cubic yard becomes the unit for loading and for dumping, whereas the yard-mile, or ton-mile, is made the unit of transportation. Still further subdivisions of some of these six processes are often desirable, yielding still other units that more closely approximate the foot-pound unit.

Therefore, our second rule is as follows: *Since construction usually is divided into processes, and since a separate gang usually performs each process, select sub-units based upon the work done by each gang.*

In order to apply this rule it frequently is necessary to reorganize the work so that each process is performed by its special gang. Where the work is not of sufficient magnitude to keep distinct gangs busy on each separate process, it is still often possible to work the same gang a few hours at one process and then shift it to another process, instead of working the same men in a heterogeneous fashion on two or more processes at the same time.

Units for Concrete Work.—The cost of a cubic yard of concrete varies between about \$2.00 for cheap pavement sub-base to about \$20.00 for certain parts of a reinforced concrete building. A hasty generalization drawn from such variations as this has led many an engineer to scout the usefulness of cost data, particularly such data as have not been gathered by the individual who attempts to draw conclusions from them. However, when the cubic yard of concrete is divided into proper sub-units of cost, it is astonishing to note the fading away of all seeming difficulties, either in estimating costs of concrete or in securing data upon which to judge the efficiency of workmen.

The labor processes in concrete may be classified as follows:

1. Receiving and storing materials.

2. Delivering materials to the mixer (loading and hauling).
3. Mixing concrete.
4. Transporting concrete.
5. Placing concrete.
6. Ramming concrete.
7. Finishing the surface.
8. Framing the lumber for forms.
9. Erecting forms.
10. Shifting and cleaning forms.
11. Taking down forms.
12. Shaping the reinforcing steel.
13. Placing the reinforcing steel.

Some of these processes may be still further subdivided, and frequently it is desirable to do so. While the cubic yard of concrete is usually a satisfactory unit for items one to six, it is clear that the square foot or square yard is a unit that must be used for item 7. Items 8 to 11 should be expressed in terms of the 1,000 ft. B. M. as the unit, and it is usually desirable also to use the square foot of concrete surface covered by forms used as another unit for estimating the cost of work on forms. Items 12 and 13 should be expressed in terms of the pound of steel as the unit, since the number of pounds of steel per cubic yard of concrete varies widely.

Two or More Units for the Same Class of Work.—As just indicated, it is frequently desirable to use more than one unit of measurement. The unit on which the contract price is based is usually a desirable one in which to express all items of cost. In addition to this, the cost of each item may be expressed in other units, such, for example, as the 1,000 ft. B. M. and the square foot of area for form work in concrete construction. Such units should be selected as will permit comparison not only of one day's work with another, but of one job with another, and frequently it is desirable to select units that may be used in comparing two entirely different classes of work.

Uniformity in Units of Measurement.—The economic importance of uniformity in units of measurement cannot be over-estimated. To illustrate: The common unit of concrete work is the cubic yard, but it is customary to measure cement walks in square feet. Now this leads to many blunders, not only in estimating the cost of walks, but in effecting reductions in cost. Not only does the thickness of cement walks vary widely, but the proportion of cement to sand in each layer of the walk is variable. Therefore, to say that it takes so many barrels of cement to make 100 sq. ft. of walk means next to nothing unless the plans and specifications for the walk are also given. For purposes of accurate estimating it is necessary to prepare tables of cost of mortars and concretes in terms of the cubic yard; then by remembering that 100 sq. ft. having a thickness of 1 inch are almost exactly 0.8 cu. yd., it is a simple matter to convert costs per cubic yard into costs per square foot.

Not only in computing costs of cement walks, and the like, but in

reducing costs, does it aid us to use the cubic yard as the unit, for it enables us to make comparisons, and thereby discover inefficiency of workers. Elsewhere in this book a case is cited where the labor cost of the face mortar for a concrete wall was out of all proportion to what it should have been. Had the contractor estimated the cost of this mortar in cubic yards, he would have discovered that it was excessive. The labor of mixing mortar should not be much greater than the labor of mixing concrete per cubic yard, nor should the labor of conveying the mortar in wheelbarrows be greater. The labor of placing it in a thin layer is obviously greater than for placing concrete in thick layers; but, in the case mentioned, the contractor was losing his money in mixing and conveying the mortar. He had not recognized the fact because he had not reduced the cost to dollars per cubic yard of mortar.

In like manner, one may often see money wasted in making and delivering mortar to bricklayers and masons, because the cost of the mortar itself, in terms of the cubic yard of mortar (not of masonry), has not been calculated.

The cost of labor on forms and falsework should always be recorded in terms of 1,000 ft. B. M., as the unit; for that is the common unit of timber work, and, being so, ready comparisons can be made only in dollars per M. ft. B. M.

It is surprising how few managers of men have realized the value of reducing the cost of each item of work to units that are comparable; and by this we mean units in terms of which entirely different classes of work may be compared. Thus, in a brick pavement there is grout used between the joints. This grout is a thin cement mortar, and it averages, let us say, 6 cents per sq. ft. of pavement. Now, what does it average per cubic yard of grout? Probably not one paving contractor in a thousand knows; but, until he does know, he cannot compare the cost of grouting with the cost of other kinds of cement work. Many a time have we had our eyes opened to unsuspected losses and inefficiencies only by reducing the costs of the elements of work to units comparable with the units of similar work in other fields.

The ton is a very convenient unit to use when comparing the cost of loading and handling materials of all kinds. The ton of brick, the ton of gravel, the ton of timber, the ton of cast-iron pipe, are loaded upon wagons by hand at a cost differing not so much, one from the other, as might at first be supposed. When reliable data are not available for estimating the cost of handling any given material, by reducing it to tons an approximate estimate can usually be made that will be satisfactory, at any rate far more reliable than a guess.

Units of Transportation.—On contract work, distances of transportation are usually so short that the percentage of time "lost" by cars, carts, etc., while being loaded, becomes a very large part of the total day's time. Hence the unit of transportation must not be simply a unit of weight, or of volume, transported a unit distance. For example, a wagon may be loaded with earth in $4\frac{1}{2}$

minutes, transported 100 ft., dumped and returned in $1\frac{1}{2}$ minutes, or less; total, 6 minutes. Of this time less than 25% is spent in transporting the earth. On the other hand, if the haul is 6,000 ft., the time spent in transporting may be 93%. The cost per 100 ft. transported is almost four times as much in one case as in the other. Therefore, unless the hauls are so long that the time lost in loading and unloading is an insignificant part of the total time, it is essential to divide the work of transportation into three elements:

1. Time lost loading.
2. Time lost transporting.
3. Time lost unloading.

Often this third item is so small that it may be disregarded. On contract work it is often necessary to have a fourth item:

4. Time lost during the shifting of tracks, and other changes in plant location.

In brief, the lost time, of whatsoever nature, must be determined and deducted from the total time, before the number of units of transportation performance can be divided by the correct number of hours.

Transportation, therefore, must be divided into two main units of cost:

1. Non-productive (lost time loading, dumping, shifting plant, etc.).
2. Productive.

The total cost of the non-productive time is divided by the total number of yards or tons moved to get the unit non-productive cost of transportation.

The productive cost of transportation is the ton-mile, the cubic yard-mile, the ton-station (station = 100 ft.), or the like.

The distance of transportation is usually computed from a map, but it is often desirable to attach an odometer to one, if not all, of the wagons, locomotives or the like.

Odometers of the kinds used on automobiles and bicycles can be advantageously used in a great many places on contract work, a few of which are as follows: On wagons, on wheel scrapers, on locomotives, on traction engines, on road rollers, on derricks (to record the number of swings), on hoisting engines, on cableway carriages, etc. Indeed, wherever a machine or tool has a revolving or reciprocating part, an odometer or counter can be used to record the number of reciprocations or revolutions, and from the data so recorded the amount of work can often be calculated with great accuracy.

Recording Single Units.—There are many classes of work in which the only practicable unit to be used is the single or individual unit itself; thus, the telegraph pole erected, the pile driven, the door hung, etc. Obviously records of units of this sort are so readily made as to require almost no comment.

A punch card is a convenient record of single units. Some contractors prefer a tally board on which each unit is marked or tal-

lled with a pencil. Others use a board like a cribbage board, having holes in which plugs are put to record the number of units. Still others give out tickets to the men for each unit of work delivered.

Record Cards Attached to Each Piece of Work.—In doing machine-shop work it is often necessary to have one piece of metal pass through the hands of several different workers. For example, one man may drill holes of a certain size, another man may drill holes of another size, still another man may thread the holes, and so on. In such a case it is common practice, where careful cost records are kept, to provide a card that is attached to each piece or each lot of pieces. In blanks provided on the card, each worker enters his number, and the number of hours and minutes spent by him in doing a specified kind of work on the piece. A modified form of this method is to attach a card or a brass check to each piece, giving a serial number and letter to the piece. Each workman on the piece notes its number on his own record card, and opposite this number he enters the amount of time spent on the piece.

While this method of recording output cannot be as frequently used in engineering contract work as in machine shop work, it should not be overlooked by the general contractor. It might well be applied to timber work where one gang of men bores the holes, another gang saws and a third gang "daps" or adzes the sticks, and so on. It is desirable always to assign different kinds of work to different men, not only because the time usually lost in changing tools may be saved, but because men become more expert when they do one class of work only. The record card facilitates the differentiation of labor into classes, and is, therefore, a great aid in increasing the output of a given number of men.

Measurements of Length.—For a great many kinds of contract work the lineal foot is the best unit to use. Track laying, fence building, pipe laying, setting curb, etc., come under this head. Many other classes of work are commonly measured only in terms of the lineal foot, when, to permit of true comparisons, some other unit or units should also be adopted. Sewer work, for example, is commonly recorded only in terms of the lineal foot; but the amount of excavation varies greatly per lineal foot in different sewers and often in the same sewer; hence the excavation should be measured with the cubic yard as the unit.

Tunnel excavation should also be reduced to the cubic yard standard. A contractor has no very definite idea whether the "mucking" (loading of cars) in a tunnel is being done economically or not until he has determined how many cubic yards each man is loading daily.

Measurements of length are often best made by driving a line of stakes 100 ft. apart, calling each stake a "station." The starting point or station is called Station 0. The next station, 100 ft. from the start, is Sta. 1; the next station, 200 ft. from the start, is Sta. 2; and so on. Hence the mark on any given station stake gives the number of hundreds of feet from the starting point. Points intermediate—that is between any two stations—

are called "pluses." Thus, a point 40 ft. in advance of Sta. 2 is called "two plus forty," and is written Sta. 2 + 40, by which it is clear that it is 240 ft. from the start.

Having driven a line of station stakes, properly marked with their station number, a foreman or timekeeper can quickly ascertain the station and plus at which the day's work has been completed.

In many instances, measurements of length are best made by counting the number of pipe lengths laid, or the number of rail lengths.

Measurements of Area.—Paving, painting, roofing, plastering, and many other classes of construction work are best measured in terms of the square yard, square foot, or "square" (100 sq. ft.) as the unit. Since areas are usually measured with ease, it is noticeable that area work is generally done with much greater economy than mass work, which is usually more difficult to measure and consequently not measured every day on most jobs. It is sometimes not easy to measure the number of thousand feet board measure in concrete forms, in which case it may be preferable to measure the area of concrete covered by the forms, from which, if desired, the amount of lumber can be calculated approximately.

Measurements of Volume.—This class of measurements is usually the most difficult to make for purposes of daily output reports. Excavation, for example, is not easily measured, as a rule, except by a surveyor. Of massive masonry the same is true. Hence there are few contractors who know accurately how many cubic yards of this sort of work should be accredited each day to each gang. Record should be kept of the number of car or wagon loads of excavated material; but, to derive much benefit from such records, care must be taken to have cars and wagons of uniform size uniformly loaded, or to keep record of the capacities of the different vehicles. Where daily measurements of volume are difficult to secure, some one or more of the following methods may be adopted.

Measurements of Weight.—Loaded cars or wagons can be weighed on track scales or on portable platform scales, and this can be profitably done far oftener than it is. Loaded skips and buckets can be weighed with spring balances attached to the hoisting rope of a derrick. It is sometimes very difficult to measure volumes of certain quantities in the field and it then becomes of advantage to weigh them. It is not easy to tell how much rock there is on a skip load without weighing the loaded skip either by placing it on scales or by putting a spring balance on the derrick. Spring balances of that character can be purchased of a capacity up to 2,500 lbs. and costing about \$150. Another form of rock measuring apparatus is in the nature of a balance, costing about \$115. A great advantage of a spring balance on a derrick is that it takes no extra time for handling, and, while the first cost seems rather high, the information obtained on a large piece of work is well worth its cost.

In a good many of the Hudson River Trap Rock Quarries the stone is handled in cars which are pushed along on the tracks for purposes of weighing and the men are paid for performance according to the weights on the cars. This is a very accurate and, where it is practicable, a highly satisfactory method of measuring output.

This method has long been in use at coal mines where every car is numbered, and is weighed before dumping.

On contract work, such as macadamizing, for example, each wagon load may be weighed, if the amount of the work warrants the purchase and use of platform scales. It is usually considered sufficiently exact, however, to measure the size of a few loads, and simply count the number of loads. However, loads often vary so greatly in size that this method of counting loads becomes very unsatisfactory. This holds true particularly of loads of quarried stone, of earth loaded by steam shovels, and the like. In such cases the contractor should seriously consider the advisability of weighing each load.

One of the most difficult classes of construction work to measure daily is rubble masonry. Yet we have found two very satisfactory methods of recording the work done by each derrick gang. One way is to use wooden skips that are loaded at the quarry with stone, put upon cars and transported to the work. Each skip is provided with a clip for holding a brass check. The checks are numbered serially, and the weight of stone corresponding to each number is entered in a book; for before delivery to the masonry derricks each skip is lifted by a derrick, placed on scales and weighed. It is sometimes preferable to provide a large spring balance for weighing, instead of using scales. The mason in charge of the derrick gang removes the brass check from the skip and keeps it, entering its number on a card which is turned over to the timekeeper at night, together with the brass checks. Thus it is possible quickly to ascertain the number of tons of rubble laid by each gang.

Functional Units of Measure.—Under this head we class all measurements of units that are functions of the desired units. Thus, in any given mixture of concrete, the number of barrels or bags of cement is a function of (i. e., it bears a definite relation to) the number of cubic yards of concrete. Hence a record of the amount of cement used each day will enable making a close approximation to the number of cubic yards of concrete.

In rubble or cyclopean masonry, a record of the number of buckets of mortar will enable making a close calculation of the yardage of masonry. If spalls are liberally used to reduce the amount of mortar, as they should be, then the number of buckets or skips of spalls should also be recorded.

The number of gallons of paint used is ordinarily a fair criterion of the area of surface painted.

By the use of packets for handling bricks, Gilbreth has developed a system of measuring the work done by each bricklayer, for count is made of the empty packets stacked up by each mason.

Since each packet is loaded with a definite number of bricks, this gives an accurate record of each man's output.

Stockpile Measurements.—There are certain kinds of construction that are best measured indirectly by ascertaining what has been removed each day from the stock piles. Thus, in erecting a frame building, the different kinds and sizes of lumber can be piled in stock piles of regular size, easily measured. Rolls of paper, bundles of shingles, etc., can be stored in such manner that a daily inventory of stock on hand is readily made. By subtracting the amount shown by the inventory at the end of each day from the amount on hand the previous day, an accurate record is obtained of materials that have gone into the building. Since a carpenter's work is usually best measured in terms of the 1,000 ft. B. M., the square of shingles, and the like, it is evident that stock pile measurements can be used to great advantage in determining the number of units of certain kinds of work performed on a building.

The measuring of material is greatly facilitated by using a standard method of handling. Glibreth's rule for cement (see his "Field System") is to place the bags one on top of the other in piles of fifty.

One of the most difficult of the materials to check regularly is the reinforcing steel for concrete. If this is handled in plain bars they can be weighed and wired in bundles of 100 lbs., this being a suitable size for two men to carry. The bundles are, of course, nearly always more or less than 100 lbs., and when the steel is wired it is a good plan to attach to each bundle a tag giving its weight, which tag can be left with the storekeeper for record as the bundles are removed to the work. The difficulty of obtaining these records is caused by the fact that the material is usually placed in a haphazard way wherever it happens to be most convenient for the men placing it without any systematic regard for its use on the work.

Key Units of Measure.—It is always desirable to relieve the foreman or timekeeper of the work of computing the number of units of work done daily, wherever such computation involves either many measurements or much labor in computing. A foreman can readily report the number of "stations" of road graded or macadamized, leaving to the office force the work of deducing the number of units of work performed.

A further step in the same direction is the use of key letters and numbers to designate sections of work whose dimensions the foreman may not know but which are recorded in the office, and from which the number of units of work performed can be readily ascertained. For convenience we call these units key units, since they are designated by key letters or numbers.

Key Units on Drawings.—Any given structure can usually be divided into "sections" identical in shape and character of work. Thus, in a concrete building, there are a number of columns of identical size, a number of beams also identical, a number of

Identical floor slabs, and so on. To each of these "sections" a key letter or number, or a combination letter and number, may be assigned and written on the drawing.

If numbers from 100 to 199 are reserved for "sections" on the first floor, and the letter C is used to denote columns, then C 100 will designate a particular kind of column on the first floor, while C 200 will designate a corresponding column on the second floor: Having assigned keys to all "sections," the foreman or timekeeper is furnished with blueprints on which the "sections" with their respective keys are marked. In some instances it is preferable to furnish only a few large blueprints containing many "sections" on each print, but it is usually desirable to supplement these large blueprints with small ones of notebook size, which, if preferred, can be punched and bound in a loose-leaf binder.

The foreman or timekeeper reports daily the number of each class of "sections" built by each gang, using the proper key to designate each "section." The office force, having computed the number of units of work in each section, is then able to record the total number of units of work done, with accuracy and with rapidity. If a full "section" is not completed, the foreman or timekeeper estimates the percentage completed, and reports accordingly.

Keys Marked on Separate Members.—On certain classes of work a modification of the above plan is preferable. Instead of providing the foreman or timekeeper with drawings having keyed "sections," a key number or letter is painted, or otherwise marked, on each separate member of the structure before it is put into place. Thus, each block of cut stone is measured in the stock yard and a "key" is painted upon it. Then, when the foreman reports that block A 105 has been laid in the wall, the office force can determine its volume from the recorded measurements. The authors have found this to be the most satisfactory method of recording cut stone work, for it is thus possible not merely to tell the total amount laid each day by several derrick gangs but to tell precisely what each gang has done, for each boss mason can be required to record the key number of every stone laid under his direction. The office work of computing the volume of each stone is insignificant in amount if tables are used for computation, such as Nash's "Expeditions Measurer" (\$2.00). These tables give the volume of any block, progressing in size by inches up to 4 ft. 9 in. x 4 ft. 4 in. x 1 ft. 1 in. The tables also give surface areas, progressing by inches, up to 4 ft. 1 in. x 3 ft. 5 in. in size.

Structural steel members can be marked with key letters; so, too, can heavy timbers, moveable sections of forms and falsework, and many other classes of materials used in construction work.

Conclusion.—Upon the ingenuity of the management engineer who devises ways of recording the daily output of work done rests the success or failure of any effort to introduce modern methods of management on complicated contract work. The problem before him is often one to tax his ability almost to the elastic limit, for it is not sufficient to devise a method of measuring daily

output after a fashion. He must devise not only an accurate method but one that permits of application at the hands of men comparatively unskilled mentally, and under the varying conditions that characterize field construction work. Many a contractor has given up in disgust his attempt to install a modern system of cost keeping and has charged his failure to the folly of "new-fangled notions." Such failures are usually the outcome of trying to teach old dogs new tricks without so much as hiring a competent teacher. Eventually, it will be recognized that management engineering is a science not to be picked up and mastered at one reading of any article or book, but that it requires study extending over a considerable period of time.

Cost Keeping.—The following pages on cost keeping have been taken from "Cost Keeping and Management Engineering," by Gillette and Dana. In this brief summary here given it is obviously impossible to give more than general principles. For further elucidation of the subject by specific examples, the reader is referred to the book from which this abstract has been made.

The two primary objects of cost keeping are:

1. To enable a manager to analyze unit costs with a view to securing the minimum cost possible of attainment under existing conditions.
2. To provide data upon which to base estimates of the probable cost of projected work.

As a result of the analysis of unit costs, followed by a comparison of the items with corresponding cost items of similar work previously done, a manager may discover:

1. Excessive use of materials in erecting a given structure.
2. Excessive use of supplies (coal, etc.) in operating a plant, whether due to ignorance, carelessness or theft.
3. Inefficiency of workmen.
4. Inefficiency of foremen.
5. Padded payrolls.
6. Excessive loss of time due to: (a) plant breakdowns, (b) plant shifting, (c) waiting for materials or supplies, etc.
7. Improper design of plant.

Cost keeping also leads to the introduction of piece-rate or bonus systems of payment, which may, in fact, be said to be one of the ultimate objects of cost keeping.

Cost keeping secures many incidental advantages, like the following:

1. Fewer "bosses" are required on certain classes of work, for the report card is a more persuasive stimulus than the eye of a taskmaster.
2. One skilled manager can direct many more men, and with much greater effectiveness than is possible where a cost keeping system does not exist.
3. Systematic analysis of costs leads inevitably to a study of reasons for differences in costs, and this study of reasons is the first step toward inventing new machines and new methods for reducing costs.

Cost Keeping Defined.—For the purpose of the discussions in this book, a distinction must be drawn between bookkeeping and cost keeping.

Bookkeeping, as we treat it, is the process of recording commercial transactions for the purpose of showing debits and credits between different "accounts." These "accounts" may be individuals or firms, or they may be arbitrary accounts, the latter being an evolution in bookkeeping that came after individual accounts became so large or so complicated as to be insufficient to show the status of the business and the profits derived from any given transaction.

Cost keeping, as we treat it, is the process of recording the number of units of work and the number of units of materials entering into the production of any given structure, or into the performance of any given operation. To these units of work or materials, actual or arbitrary wages or prices may or may not be assigned. The object of cost keeping is primarily to show the efficiency of performance; hence actual money disbursements need not be recorded, as in bookkeeping. This distinction is vital, and will be discussed at greater length.

Differences Between Cost Keeping and Bookkeeping.—Bookkeeping was first devised and subsequently developed by merchants. Cost keeping was devised and developed by engineers. The merchant is a student of profits; the engineer is a student of costs. Although profits depend upon costs, there is a vast difference in the point of view of the merchant and the engineer.

In the study of costs, as we have previously pointed out, the aim of the engineer is to reduce all costs to a unit basis, selecting such units as most closely conform to the theoretical unit of work—the foot-pound. This study often necessitates the use of several different units for the same class of work. It necessitates the recording of conditions, and the making of measurements—all of which is more or less foreign to the fundamental idea of bookkeeping. Yet, in groping toward methods of cost keeping, it has become the practice of most contractors, manufacturers, railway companies, etc., to endeavor to develop a cost keeping system in the bookkeeping department. Hence we have to-day systems of bookkeeping that are wonderfully complex, and, withal, show very little that they attempt to show as to unit costs.

Take, for example, the accounting department of an American railway. Here we find skilled accountants loaded up with a mass of work called for in distributing the costs to different accounts. Calculating machines that carry the cost of railway spikes out to the third decimal place are clicking away from morning to night. A prodigious amount of figuring is done so that scores of distributions may be made, without the error of a cent in the balancing of accounts. Yet, with it all, what do these railway accounts show as to unit costs? Next to nothing worthy of the name of cost keeping. The authors have in their possession a mass of railway accounting records; some of it of great value, but most of it valuable only to show bookkeeping gone mad. The accounting department of the average railway has no true record of unit costs.

The average railway engineering department is even worse off, as shown by the ridiculous estimates often submitted. After a structure is built, the auditor of the railway takes the superintendent of construction to account for having exceeded the engineer's estimate. The engineer is put on the rack and calls the superintendent inefficient—which is usually true. The superintendent retorts, in his letter to the accounting department, that the engineer does not know how to estimate correctly—which, also, is usually true. Figures, figures, figures, but not a single unit cost! This is typical of railway accounting costs to-day. We emphasize it because it is also typical of the accounting departments of many contracting firms. And we emphasize it again because it illustrates so well our contention that bookkeeping and cost keeping must be divorced if there is to be a simple, effective system of ascertaining the efficiency of workmen, and permit of such study of their performance as will result in greater efficiency.

We shall now give in concise form some of the various reasons why cost keeping records should be kept entirely distinct from bookkeeping records.

1. Since the primary object of *bookkeeping* is to show debits and credits, all accounts must be summarized in one book—the ledger. Since the primary object of *cost keeping* is to reduce costs, no book corresponding to a ledger is needed. Indeed it is often desirable to have cost records of different classes of work kept in different books, in different ways, by different men, in order to localize responsibility as well as to apply different units as standards of comparison.

2. *Cost keeping* should partake of the nature of daily reports by which a superintendent can gage the daily performance, and discover inefficiency at once. *Bookkeeping* accounts may not be, and usually are not, posted promptly or completely until some time subsequent to any performance.

3. *Bookkeeping* records must balance to a penny. *Cost keeping* records need not be kept with mathematical precision, except in so far as bonus payments to workmen are involved. The object of cost keeping is to show efficiency, and this may usually be shown by approximations fully as well as by hair splitting exactness. Hence cost keeping records may be devised that will require far less clerical work than is necessary when mathematically accurate bookkeeping is used.

4. *Bookkeeping* is a clerical function; *cost keeping* is an engineering function. It is a rule of successful management not to ask one man to exercise many functions, particularly when they are diverse in nature. An engineer is not interested in recording debits and credits, or in the rendering of bills—functions of the bookkeeper. On the contrary, a bookkeeper knows nothing about construction methods and not only has little interest in construction costs, but lacks the necessary engineering training to interpret cost records and to devise methods of reducing costs.

5. A contractor who has an effective and simple system of bookkeeping naturally objects to a change to a more complex sys-

tem, such as is necessary when cost keeping is added to the bookkeeper's duties.

6. When cost keeping is begun, it is well to start in a small way, taking some particular kind of work, like teaming, and applying a system of daily reports. When this phase of the work has been analyzed and organized, some other feature is taken up, and so on, thus developing a cost keeping system gradually. Resistance to change is bound to be encountered, and the way to overcome it is in this manner, a little at a time. Bookkeeping cannot be changed a little at a time. A new system of bookkeeping means an entire revision all at once, for accounts are interdependent.

7. Cost keeping records should state conditions, such as weather, distance of haul, etc., which are essential to interpretation of results. Sketches showing design of structures should form part of permanent cost records. Such things are entirely foreign to bookkeeping, and, if placed upon bookkeeping records, simply serve to confuse them.

8. The bookkeeper enters bills for materials as they are received, crediting the firm that furnishes them. A barrel of spikes may be followed by a dozen picks on the bill. It is not the bookkeeper's function to trace the spikes to their place in the work, and, when the work is finished, to ascertain the total number of barrels of spikes used in a particular structure. That is the function of the cost keeper on the ground. The bookkeeper must show that John Smith Co. has been credited with the spikes. The cost keeper, on the other hand, cares nothing as to the particular firm credited. He is concerned only with the quantity of spikes and the use to which they have been put. It is hopelessly confusing to try to show in one set of records both credits, and unit costs.

9. In studying cost records to ascertain efficiency, it is often necessary to have several different units as standards. On reinforced concrete work, for example, the primary unit is the cubic yard, but there should be at least three other units, namely, the pound of steel (for comparing costs of handling and placing the steel reinforcement), the thousand feet B. M. (for comparing costs of forms), and the square foot of exposed surface (not only for comparing costs of form work but costs of surface dressing). Cost records must be sufficiently detailed for these purposes, if not in every case, at least in some cases of concrete work. Bookkeeping records become hopeless of interpretation unless they are uniform, and, to be uniform, they must have few units of comparison. In brief, bookkeeping is not flexible. To generalize further, cost keeping costs must be divided by units of work done, so as to secure unit costs for comparison, which is a process foreign to bookkeeping.

10. Since cost keeping has as its primary object the reduction of costs, since comparison of results secured by different men or different machines or different methods are necessary, it follows that standard wages and standard prices of materials must be used. It may happen that on one job the cement may be purchased at different times at prices ranging from \$1.20 to \$1.50 per barrel, and that common laborers may receive from \$1.50 to \$1.75 a day

In comparing unit costs a standard price of cement should be assumed, as \$1.30 per barrel, and a common labor standard wage, as \$1.50 per day. Then comparisons become possible. A bookkeeper cannot assume any rate of wage or any price; he must give the actual wage or price. A cost keeper usually finds it desirable to use standard wages or prices which approximate the average, or actually are the average.

Time Keeping Defined.—Time keeping, in its old fashioned sense, is a part of the bookkeeping system, and the timekeeper is charged with the task of ascertaining what time each man has worked during the day, week or month, according to the arrangement under which he is employed, and what amount of money is due him on pay-day. The timekeeper was not concerned with how much work a man did or on what process his time was spent, so long as the general distribution of the work was obtained. Of late years the timekeeper's distributions have become much more elaborate and now he is often charged with considerable cost keeping responsibility. When he does cost keeping work, the records should ordinarily be kept on separate blanks from the time keeping.

If a timekeeper, unaided, attempts to distribute the labor according to the work done, his records become complex and are rarely reliable, for, due to his going from place to place, he must rely upon what others (like foremen) tell him as to the performance of different men. In his attempt to balance the statements made to him with the total time, he usually "fudges" his distributed records.

Daily Cost Reports, By Whom Made.—Daily cost reports may be made by: (a) individual workmen, (b) foremen, or (c) timekeepers, or by all three of these classes of employees.

Individual workmen are not always competent to fill out reports properly, but, if the report is simple in form and relates to work done by "skilled workmen," it is usually possible to get very satisfactory results. Certainly the individual report is to be encouraged wherever it can be applied, for it heightens the individual's interest in his work.

On field contract work the foreman is the man usually required to make the daily reports. His constant presence on the work enables him to make a more accurate report than a timekeeper can make, if the timekeeper is required to cover considerable territory, as is usually the case.

In addition to his duty in keeping the time of the men for purposes of paying them properly, the timekeeper is often able to attend to filling out the daily cost reports, or one or more special timekeepers may be appointed for the special purpose of rendering daily cost reports. If the timekeeper is not able to be present constantly where a gang is at work, it is often wise to prepare certain blanks upon which he receives reports from the foreman of the gang, and, from this foreman reports and reports of individuals, combined with his own observations and measurements, the timekeeper is able to fill out the complete report.

No hard and fast rule can be laid down as to the best persons

to whom report making is to be entrusted. The character of the workmen, the size of the job, and other conditions govern the choice.

Written Card vs. Punch Card Reports.—Daily cost reports are best made on forms or blanks, and these forms are preferably cards in which the blank spaces are marked either in writing or by punching holes with a conductor's punch. The written card possesses the following advantages over the punch card:

1. It is more flexible, because the punch card is limited in the scope of the record to what has been foreseen in the office plus what can be written in a small space reserved for remarks. The pad and pencil are not so limited.

2. A man can usually go ahead filling out blanks in a written card without any previous directions, while he has to have some instruction in the use of the punch.

3. Erasures are possible with pencil and pad but not with a punch card. This is not always an advantage on the side of the written card, however.

The punch card possesses the following advantages over the written card:

1. By folding the card, or by superimposing one card on another, a duplicate record is secured without the use of the carbon paper necessary to secure duplicates with written cards. This duplicate record cannot be altered or erased, and one copy may be kept by the superintendent for his record in discussing the work with the home office, the other being sent in as a regular report to the proper department.

2. A dirty thumb can greatly interfere with the legibility of a written record. Moreover the average foreman or time keeper does not write a particularly clear hand. Punch card records are absolutely clear and legible.

3. It is sometimes expedient to have records from two or more men on the same card. By having no two punches alike on the job and having each man's punch charged to his name on the records it is possible to have a clear and complete record of who made the record without wasting time and space for signatures.

4. The hole made by the punch is usually less than one-eighth of an inch in diameter, and consequently a much larger number of facts can be recorded upon a small card by the punch than by writing, the number of groups of facts, however, being somewhat limited.

5. To punch a hole in a card takes much less time than to make the average pencil record, especially where duplicate records are made. Where a time keeper has to keep track of a large number of men this is a very valuable feature.

6. A hole can be accurately punched while riding on a hand-car, wagon or locomotive, when the vibration would greatly distort a man's handwriting.

7. Punch cards can be made on blue print paper from a tracing, which is an advantage where a mimeograph is not available for making white cards to be filled in with pencil.

Time Cards that Show Changes of Occupation.—In field contract work there is usually more or less change of occupation constantly occurring. A gang of workmen may be engaged in grading for a while and then may be shifted to track laying; or at least some individual in the gang may be thus shifted from one class of work to another. Hence it is usually desirable to have daily report cards arranged so as to record the exact amount of time spent by each individual on each class of work. This may be accomplished in either one of two ways: First, by having a separate card for each workman; or, second, by having a gang card on which each workman's name or number appears, and so arranged that his time may be placed opposite or under the tabulated class of work that he has performed.

The individual card (a card for each workman) is often preferable when the bonus system, or its equivalent, is employed. On most contract work, however, the bonus system is not yet in operation, and gang cards, filled in by the foreman, will serve the purpose of showing the total performance of the gang and the times spent by the various individuals on different work. There are several ways of recording the individual times spent by men working in a gang, among which the following are typical.

Each employee is given a number, and the numbers are arranged in a horizontal line across the top of a time sheet, as shown in Fig. 4. The different classes of work are printed in a column at the left, one line being assigned to each subclass. If team No. 1 works from 7 to 9 a. m. plowing, the record is made by the foreman, who writes 7-9 opposite "Plowing" and under No. 1; since this is 2 hours' work, the figure 2 is subsequently written directly below the 7-9. If team No. 1 is then transferred to work connected with rolling subgrade, and is thus engaged from 9 to 11 a. m., this fact is indicated, as shown, by writing 9-11 under No. 1 and opposite "Rolling Subgrade."

Another method involves the use of "key letters" to indicate each class of work, the proper key letter being placed opposite the employee's name and under the nearest half hour when he began doing the class of work represented by the key letter. Fig. 5 shows that employee No. 1, whose name is Smith, began work at 7 a. m., the key letter *A* being under 7, and that he was engaged in excavation, since *A* is the "key" for excavation. He continued on excavation until 10:30 a. m., when he began backfilling, as shown by the key letter *C* entered under 10 and in the lower square. The upper squares indicate the even hour, and the lower squares indicate the half hour. At 3 p. m. he was transferred to concrete work, as shown by the key letter *F* under 3, where it will be seen that the number of hours worked by each man on each class of work is recorded under a column headed with a combination of key letters that indicate the class of work.

Wherever men are being frequently shifted from one class of work to another, some method of recording the time of shifting, at least to the nearest half hour, should be used, as outlined in the different ways above given. If a foreman does not make an imme-

classes of work; but, if a blank must be filled in during the progress of the work, and not at night, a foreman risks discovery of any attempted deceit, since his record card may be examined at an unexpected time of the day.

Gang Report Cards.—These are usually made by the foreman in charge of the gang. If the gang is always engaged on the same class of work, it is not necessary for the foreman to keep a time record of each man's occupation, in the manner just described; for the foreman can fill in the daily report card from memory. In this case the *timekeeper* records each workman's name and hours of work, while the foreman concerns himself only with reporting the total number of men engaged on each class of work and their day's performance.

A gang report card should usually show most of the following things:

1. Number of contract.
2. Location of the job.
3. Character of the job.
4. Date of the report.
5. Kind of weather.
6. Name of the foreman.
7. Classification of work, or "key letters."
8. Total hours labor under each class.
9. Rates per hour.
10. Total pay.
11. Number of units of each class of work done.
12. Units of material and supplies used.
13. Units of materials received.
14. Units of material in stock.
15. Delays, time and cause.
16. Time machines are actually working.
17. Kind of machine or tool used and its condition.
18. Remarks.

Obviously there are many classes of work that do not require a daily statement containing all these 17 facts; but in preparing a daily report card it is desirable to have this list at hand, to make sure that no omissions occur.

The space reserved for "Remarks" is usually so small that it is rarely used. Special conditions that would naturally be recorded under "Remarks" had better be recorded in a loose leaf diary kept by the foreman, of which more will be said later.

In designing a gang report card, the most difficult feature is the classification. This, however, is greatly simplified if done according to the following system:

1. Select for the general class heads the items upon which the unit contract prices are based, such as excavation (cu. yds.), macadam (sq. yds.), curb (lin. ft.).
2. Divide each of these pay items into the operations involved. Thus excavation involves (a) loosening, (b) loading, (c) transporting, and (d) dumping.
3. Divide each operation into as many subheadings as there are

classes of workmen engaged upon it. Thus, the operation of loosening earth may involve (a) teams plowing, and (b) men holding plow.

Summing up we would have the following subclasses under the class Excavation:

Excavation—

Loosening: Men holding plow.

Teams plowing.

Loading: Men shoveling.

Transporting: Teams.

Dumping: Men.

The next thing to consider is whether the men are of the same class, receiving the same rates of wages; for, if they are not, there must be a further subdivision. For example, on cement curb construction, the classification would be as follows:

Curb—

Trenching: Laborers.

Placing cinders: Laborers.

Mixing and placing: Laborers.

Setting forms: Skilled laborers.

Finishing: Skilled finishers.

Helpers.

There are many kinds of pay items, such as macadam, that often involve processes that are performed at widely separated places. Thus, quarrying and crushing are processes far removed from spreading, rolling and sprinkling the macadam. Whenever this is the case, it is usually unwise to attempt to show all the processes on one report card. A good general rule to follow is to group together on the same report card only those processes that come directly and constantly under the eye of one foreman. Therefore one report card should show the quarrying and crushing, another should show the grading of the road; and possibly the spreading, rolling and sprinkling of the macadam should also be placed upon the same card with the grading, but not unless the grading gang is to be always a very short distance in advance of the macadamizing.

The commonest mistake in designing report blanks is to endeavor to reduce the number of the blanks. It is far better to have more blanks and to distribute the work of reporting, for it not only simplifies the blanks, but, by giving each foreman less to report, greater accuracy is secured. In fact, there are many operations that can best be reported by the workmen themselves. Thus, to continue the illustration of the macadam road work, each of the teamsters hauling broken stone should carry an individual report card which is punched or marked by workmen at each end of the trip.

We have said that the pay items should be analyzed according to the operation involved, but care must be taken not to select operations upon which men are engaged for but a few moments continuously. To illustrate: In mixing concrete by hand, there are usually the following operations: (a) loading wheelbarrows, (b)

wheeling, (c) mixing, (d) loading, (e) transporting, (f) spreading and ramming. Some gangs are so organized that a few men are kept constantly busy loading wheelbarrows with sand and stone, while the rest of the gang spends a few minutes wheeling, a few more mixing, and so on. Clearly it would be foolish to subdivide the operations on the report cards where the organization is of this character, for most of the men are changing their operations so frequently that a foreman would have time left for doing nothing but to record their changes.

We see that the designer of a report blank should know approximately what the organization of the gang and what the methods of operation are to be, before he can design a report blank that will be concise, and complete, but with no superfluous headings. Since there are almost innumerable methods of doing work, it is obviously impossible to furnish a set of printed report cards that will exactly serve all cases, unless the classification headings used are very general. However, the designing of a report card is a comparatively simple matter once the organization and methods of doing the work are known, provided the foregoing system is used.

A tentative report blank can be designed either by using some existing report card for similar work as a guide, or by referring to some book that gives, in detail, the costs of construction work similar to that for which the report blank is intended. From the items of cost given in published records, a classification can be prepared that will be of decided help in planning the report card.

In order to economize space on a report blank, it is not always necessary to print the classes or subclasses in full. Abbreviations and key letters may be used. Sometimes the mere recording of the rate of wages opposite a class will show the subclass. Thus, under the class of "Forms" (building wooden forms for concrete) if a wage of 20 cts. per hour appears, also a wage of 35 cts. per hour, it will be understood that the latter refers to the carpenter, while the former refers to the carpenter's helper.

Having decided upon the classification of operations and employees, the next thing to determine is the character of the performance report which is usually to be recorded on the same card.

We have discussed the difficulties of reporting daily performance, and have indicated ways of overcoming the difficulties. It is evident that a foreman or timekeeper should not be expected to report the number of units of each class of work performed if any considerable amount of difficult measurement is involved. Hence, it is usually futile to provide for a daily report of the number of cubic yards of earth excavated. On the other hand, the number of wagon loads, or car loads, may usually be reported, and the blank used for excavation should usually provide for such a report.

If some of the excavated material is shoveled directly into the embankment or hauled by scrapers, while some is hauled by wagons, it will be futile to provide for a daily report of loads hauled. In such cases, it is often advisable to report merely the number of lineal feet of work done daily. Thus, in road work, where the excavation is shallow and mostly from ditches, the

report should show the station and plus up to which the grading is completed at the end of the day. It is then the function of the office force to determine the yardage from the office records.

The amount of concrete and cement work of all kinds can be reported with considerable accuracy by stating the number of bags of cement used during the day.

The amount of supplies, like coal, used each day, can usually be reported if some system is devised for recording consumption or for readily inventorying the stock on hand each night. It is generally wise to require coal to be measured in boxes or in wheelbarrows of uniform size, uniformly filled. Then each fireman reports the number of cubic feet (or boxes) of coal used during the day.

Empty dynamite boxes are often convenient for purposes of measurement, as they hold exactly $\frac{3}{4}$ cu. ft. each.

Individual Record Cards.—Wherever individual workmen are paid by the bonus or price rate systems, it is usually best to provide a separate record card for each workman, for it is difficult to make a compact record on one card that will show not only the occupations of a number of men, but the performance of each man. This is particularly true where the men are repeatedly shifted from one class of work to another.

Where one man operates a machine, like a rock drill, it is usually wise to provide him with his own individual record card, upon which he is required to record his day's performance. A modification of this plan is to let the foreman carry the individual records of all the men, and fill in each card himself.

The engineman on a dinky locomotive should be required to make and fill in a daily report, showing the number of train loads hauled, time lost, etc.

A teamster should usually be required to carry a card whereon are recorded the times of arrival or departure at each end of each trip.

A steam roller engineman should be required to fill in a card report showing number of lineal feet of road rolled, and the number of miles traveled by the roller. The latter should be recorded by an odometer.

Kind of Punches to Use.—If punch card reports are to be used, an ordinary conductor's punch will serve for small cards; but it is generally desirable to have large cards, which necessitates the use of a special punch having a 2-in. reach. Such special punches are made by L. A. Sayre & Co., of Newark, N. J., and by other railroad supply concerns.

Size and Kind of Daily Report Cards.—It is usually desirable to have report cards of a size that will be suitable for filing in the standard card index files. A size that will be found satisfactory for general use is 5 x 7 $\frac{1}{2}$ ins.

If reports are to be written and made out in duplicate, the report cards should be made up in pads of alternate thin and thick cards, so that a carbon paper may be inserted between a thin card and a thick one.

It is generally wise to have the cards tinted one color for the original and another color for the duplicate. It is also a good plan to designate the kind of report card by a key letter, or combination of letters, which may be stamped in red in one corner of the card. Thus the letter T may be used to designate the daily report card of teamsters. Instead of using mnemonic key letters, some contractors prefer to use different tints for different classes of report cards.

This works well when there are only a few classes, but becomes confusing when there are many, and is worthless as a means of distinguishing cards at a glance when there are very many classes.

Where a great deal of information must be crowded on one card, it is often desirable to provide for writing the report on both

Fig. 6. Punch Card For Teams.

faces of the card. This is objectionable, however, because it makes it impracticable to produce a duplicate by the use of carbon paper. It is also inconvenient to examine such a card after it is placed in a filing case.

Foreman's Diary.—The foreman or the superintendent should usually be required to keep a daily diary in which should be entered:

1. Verbal orders received from engineers and owners.
2. Verbal requests made to the engineers for grade stakes, etc.
3. Weather conditions.
4. Remarks as to hardness of digging, poor quality of materials and supplies, slowness of their delivery, general inefficiency of the men available, and such other conditions as bear upon the eco-

work performance of the work but can not be shown in the daily report.

The ordinary field foreman will not keep a diary of much value unless its pages are inspected daily. This requires that it shall be a duplicate loose leaf diary, the original leaf being sent to the office with the daily cost report, and the duplicate, or carbon copy, being retained by the foreman and bound in a loose leaf binder.

Designing Punch Card Reports.—We have already enumerated the advantages of the punch card for certain kinds of daily reports. One of the earliest punch cards devised for this purpose is shown in Fig. 6, and was designed by one of the authors for recording the daily work done by each team in hauling broken stone for macadam. Each teamster carries a card which he presents for punching at each end of the trip. The diamond punch hole indicates that the loaded team left the crusher bin at 7:05 a. m. The cross punch holes shows that it dumped its load on the road at 8:20 a. m. A new card is issued to each teamster each day; but, if it is desired to provide one card that will serve for a full week, one is easily designed.

A more elaborate form of individual punch card is shown in Fig. 7, and is designed to show the daily performance of each rock drill in great detail and in duplicate. Note that the upper half of the card is to be folded back on the lower half, so that the holes are punched in duplicate.

The punch holes in this particular card show:

1. That the holes were spaced 4 ft. one way and 5 ft. the other.
2. That + bits were used.
3. That the drill was in good condition.
4. That the drill was No. 2.
5. That a 3-in. starting bit was used.
6. That 54 ft. of hole were drilled.
7. That there were 4 holes, Nos. 1, 2, 3 and 4, whose depths were 15, 14, 13 and 12 ft., respectively.

(Note: A hole, No. 0, is provided, in case a partly drilled hole of the previous day has to be completed, for, in that event, the number of feet drilled to complete the hole is punched above hole No. 0.)

1. That the date was July 16.

2. That work began at 7.02 a. m., and hole No. 1 was completed at 9:44; that work was stopped at 12 m. and begun again at 1 p. m.; that hole No. 2 was finished at 1:18 p. m., hole No. 3 at 2:36, hole No. 4 at 4:52.

It is not usually necessary to record rock drill operations to the nearest even minute, as the nearest 5 minutes will ordinarily suffice; but it is sometimes desirable to have the drillers record the time of starting one hole and of starting the next hole. In that case this card, which provides for a time record on 2-min. intervals, is more satisfactory than one designed for 5-min. intervals. Drillers are often very slow in shifting drills from one hole to the next, which is well shown up if the time of finishing one hole and of starting the next is punched. Punching two holes in the card in one

square (punching double), can be used to indicate time of starting a hole, while punching one hole indicates its time of completion.

Note that in designing punch cards, space can be economized by the arrangement shown in the upper left hand corner of Fig. 7

Fig. 7 Duplicate Punch Card.

where the upper line indicates "tens" and the lower line indicates "units."

On some classes of work, particularly shop work, it is often de-

desirable to have a separate punch card for each class of work, instead of recording several classes of work on the same card. Fig. 8 illustrates such a card that has been used by the National Switch & Signal Co. and was described by Mr. Chas. Hansel and published in the "Complete Cost Keeper," 1903. Each workman perforates the 5-min. time card for each job on which he is employed, simply piercing the card at the 5-min. points most nearly representing his times of beginning and ending work on the job in hand, the appropriate order number being entered on the card by the foreman. When the workman enters the shop in the morning, he is furnished with one time card, which he hangs on the upper hook of his individual time board, after perforating it at his beginning time. If the foreman gives the workman a second job before the first is completed, he fills in the order number on a second card,

WORKMAN'S NO.	DATE
Date Commenced	7 5 10 15 20 25 30 35 40 45 50 55
Order No.....	8 5 10 15 20 25 30 35 40 45 50 55
Catalog No.....	9 5 10 15 20 25 30 35 40 45 50 55
Number Pieces	10 5 10 15 20 25 30 35 40 45 50 55
Operation No.....	11 5 10 15 20 25 30 35 40 45 50 55
Date Finished.....	12 5 10 15 20 25 30 35 40 45 50 55
Approved	1 5 10 15 20 25 30 35 40 45 50 55
.....Foreman	2 5 10 15 20 25 30 35 40 45 50 55
	3 5 10 15 20 25 30 35 40 45 50 55
	4 5 10 15 20 25 30 35 40 45 50 55
	5 5 10 15 20 25 30 35 40 45 50 55
	6 5 10 15 20 25 30 35 40 45 50 55

Fig. 8. Punch Card.

and hangs this second card on the upper hook. Thus the workman may have any number of jobs before him, each order being given on a separate card. When any job is completed its card is transferred to the lower hook. The time cards on the lower hook are removed by the timekeeper each morning, cards on the upper hook being left undisturbed.

Record Cards Accompanying Each Piece of Work.—In doing machine shop work, it is often necessary to have one piece of metal pass through the hands of several workers. For example, one man may drill holes of a certain size, another may drill holes of another size, still another may thread the holes, and so on. In

such a case a record card may be attached to, or accompany each piece or lot of pieces. In blanks provided on the card, each worker enters his number and the amount of time spent in doing a specified kind and amount of work on the piece.

Using Several Record Cards, One For Each Piece of Work.—A method that is usually preferable to the one just described for shop work, is to give each workman several record cards. As each new piece of work comes to him, he enters its "order number" on a record card, and records the time he spends on the piece. When finished, he uses another record card for the next piece.

Store Keeper's Reports.—The store keeper's duties include the following:

1. He must receipt for and take charge of all material delivered for temporary storage.
2. He must see that all of this material is properly accounted for and none lost or stolen.
3. He must take charge of the issuing of materials and supplies to the men and see that they are issued in proper quantity and that there is no waste.
4. He should see that needed material and supplies are issued without loss of time.

To accomplish these objects it is necessary that some one be on hand at the store house at all times when material is likely to be delivered or called for. This includes the noon hour as well as other times. Considerable economy results from sending to the store house in the noon hour to obtain articles that are needed in the afternoon.

The second duty of the storekeeper is often interfered with by men going to the store house for articles needed in a hurry and not leaving receipts for them. The only way, then, that the storekeeper can account for his materials would be by periodical inventories, and then at the best there is nothing whereby the periodical inventory can be checked. The perfunctory inventory is generally useless. All the men in the field in the position of authority or who are likely to require to have materials issued to them should be provided with small requisition blanks, and the storekeeper should require a requisition slip as a receipt for all material issued.

At the end of the month these receipts for material issued should tally with his inventory and list of material received.

Reports on Materials and Supplies.—Fig. 9 is a card for reporting supplies received. It includes the oil, waste, powder, caps and fuse supplied to the various field organizations, such as drillers, pumps, various steam shovels, dipkeys, cars, shovels, and also shows the amount remaining on hand. This is for steam shovel work in rock.

Fig. 10 is material card designed to be used daily by the foreman on concrete work for recording the materials received. The size of various loads of cement, gravel, sand, screenings, stone, and the number of feet board measure of lumber are shown on one half of the card, and on the other half are the amounts of glass, steel,

Fig. 10. Materials Report.

lampblack, oakum, nails, etc. On the back of the card an entry is supposed to be made of all material sent away from the shop or remaining on the work at night, thus giving a check upon the quantity of materials used.

Checking the Accuracy of Reports.—Systematic checking of the accuracy of reports made by individuals or foremen is of paramount importance, for, unless this is done, there is apt to be gross falsification of the reports in order to make a favorable showing of performance. Thus, if a drill runner is not checked occasionally as to his report of number of feet drilled, he is apt to add several feet to his actual performance.

On one railway with which the authors are familiar, the master mechanic is in the habit of reporting the time of men spent in building new cars as if it were spent in repairing old cars. The object in doing this is to make a creditable showing of the cost of making new equipment. While it is true that this seems like robbing Peter to pay Paul, it must be remembered that there is usually great difficulty in determining just what is a reasonable cost of repairing a car, whereas there is no difficulty in fixing upon a reasonable cost of making a new car.

So many men are dishonest, particularly in ways that are not actually criminal, that implicit trust should not be placed in reports that are not verified by systematic investigation at unexpected intervals of time, if they are not subject to constant checking.

On construction work it should be the duty of someone to make reports that will check the reports made by individual workmen and by foremen. The timekeeper is usually the man upon whom part of this checking devolves. Thus, the timekeeper may be required to make certain measurements at the close of the day, from which a foreman's report of performance can be checked, as, for example, the number of drill holes and the depth of each. The timekeeper may also be required to visit each part of the work frequently, noting the number of men engaged in each class of work at the time of each visit. Frequent visits are often made possible by providing the timekeeper with a horse or a motorcycle.

Checking the distribution of the men of a gang, as well as observing the energy with which they are working, may frequently be done to advantage by means of a telescope or field glasses in the hands of an observer located in a tower or on some high point of ground.

By requiring different foremen and different individuals to report on the same performance, an excellent check can often be secured. Thus, the dinky locomotive engineman should report the number of trains hauled, and either the dump foreman or the steam shovel engineman should render a similar report.

The monthly estimates of engineers should, of course, be used to check the daily reports of foremen, as far as possible; and on large jobs it is often desirable for a contractor to employ engineers to cross-section and measure the work once a week, if not more frequently.

Where the gang under a foreman is frequently shifted from one class of work to another, the foreman should always record the time that the change is made, in one of the ways already indicated. When this is done, the superintendent or walking boss should examine the foreman's record occasionally, during the day—not necessarily every day—to assure himself that the foreman is posting the record properly and at the time each change is made.

There should always be some system of recording the receipt of daily reports at the office. This is sometimes effected by having a tabular list of all the reports that should be received, and by placing a check mark opposite the name of each report (or each foreman or individual making the report) under the day of the month to which the report relates. A glance at such a tabulation shows whether any report is missing.

If it is the practice to plot or chart the returns shown by each report daily, then no further check may be needed to show that the report has been received.

One of the advantages gained by divorcing cost keeping from bookkeeping is the check thus obtainable on both. The aggregate weekly payroll shown by the timekeeper's report should check fairly well—not necessarily with great precision—with the aggregate payroll deduced from the foreman's reports. Incidentally this check makes it more difficult for a timekeeper to "pad the payroll," that is to enter fictitious names upon the payroll or to credit a man with more time than he is entitled to. Many a contractor has been robbed in this manner.

If the distribution of costs shown on the books corresponds with the distribution derived from the daily report cards, a fairly close check is obtainable.

It is generally wise to have accounts for each of the main items of materials and supplies, such as lumber, cement, coal, explosives, etc. Then the total consumption of coal, for example, as deduced from the foremen's daily cost reports, should check fairly well with the amount purchased, as recorded by the bookkeeper. Likewise the bookkeeper may divide the payroll into certain general classes of labor and assign an account for each class, which should check with the cost records turned in by the foremen. But, in our opinion, it is a serious mistake to encumber the bookkeeper with a multiplicity of accounts intended either to show detailed costs or to check the various details of cost deduced from the daily cost reports.

Cost Charts.—For showing relative performance or relative unit costs, no method is so satisfactory as a diagram or chart. A glance at the unit cost line plotted on a chart shows the manager whether there is cause for congratulation or alarm. The up and down waves of a cost line are far more impressive than columns of figures ever are.

A chart of daily performance has the incidental advantage of affording an automatic check on whether all the daily cost reports have been turned in or not, for without the reports the lines on the chart cannot be plotted.

Progress Charts.—It is generally desirable to record graphically

the progress of each particular class of work on a contract. This is best done by means of a progress chart similar to that shown in Fig. 11.

This chart relates to excavation. The first column is a percentage column. The second column gives the length of the excavation (trench, ditch, or the like). The third column gives the number

Est. Schedule	Per Cent	Length	Cu Yds.	Est. Cost	Actual Cost	Actual Cost	Actual Schedule
June 24	100	775	1600	8000			
	95		1500				
	90	700	1400	7000			
	85		1300				
	80	600	1200	6000			
	75		1100				
June 17	70		1000	5000			
	65	500	900				
	60		800	4000			
	55		700				
	50	400	600	3000			
	45		500				
	40	300	400	2000			
June 10	35		300	1000			
	30		200				
	25	200	100				
	20		100				
	15	100	00				
	10		00				
	5		00				
June 3	0	00	00	00			

Fig. 11. Progress Chart.

of cubic yards. The fourth column gives the estimated cost. The fifth column gives the actual cost; a sixth column of actual cost is provided in case it overruns the estimated cost. The total length of the excavation to be done is 775 ft., which is written opposite the 100%. Then the length column is divided into 7¾ parts, each representing 100 ft., or a "station."

The total yardage in this length of 775 ft. is 1,600 cu. yds., which

is also written opposite the 100%. Then this yardage column is divided into 16 parts, each representing 100 cu. yds. The work has been estimated to cost 50 cts. per cu. yd., therefore the total cost of the 1,600 cu. yds. should be \$800, which is written opposite the 100%; and the estimated cost column is divided into 8 parts, each representing \$100.

This work on section of excavation is scheduled to begin June 3, as indicated in the space to the left of the per cent column and at the bottom; and it is scheduled to be finished in three weeks, as indicated.

The work is begun on schedule time, June 3, as indicated by the entry to the right of the last column, and at the end of the first week (beginning of the next), June 10, the progress and cost are shown by the hatched portion below the heavy black line. It will be seen that the excavation has been completed to station 1+50 (=150 ft.), as shown in the second column; and that 350 cu. yds. have been excavated, as shown in the third column. The estimated cost of the 350 cu. yds. is \$175, as shown in the fourth column. The actual cost has been proved to be the same as the estimated cost, or \$175, as shown in the fifth column. The yardage completed up to June 10 is 22% of the total, as seen by comparing the first, or percentage, column with the third, or yardage, column, whereas, to have lived up to the estimated schedule, 33% of the yardage should have been excavated by June 10.

The performance of the next week is similarly shown by the heavy black line opposite June 17, which shows that 47.5 ft. of length (reaching therefore to Sta. 4+75) and 900 cu. yds. have been completed. The total actual cost is now \$400, as compared with an estimated cost of \$450, showing that the work is being handled satisfactorily.

If the chart is plotted on tracing cloth, blue prints are readily made. Instead of cross-hatching the performance area of each week, paints of different tints may be used.

On jobs of long duration, a similar chart showing progress by months is usually desirable, in addition to a weekly progress chart. Then it is often desirable to paint the area on the monthly progress chart, using colors of paints to designate the different months.

Methods of Payment in Proportion to Performance.—The fundamental law of management involves that payment for work done shall be proportionate to performance—that is, an increased number of units of work done by a man shall result in his receiving increased pay. The ordinary wage system is based upon this law, but only in a very crude manner, since it throws men into large groups or classes, individuals of which receive the same pay, or practically so.

We shall now consider some of the various methods that aim to recompense a workman in proportion to his performance.

Profit Sharing.—According to the method of profit sharing, each individual receives not only his wage but a pro rata of any profits that arise from the business. Either quarterly, semi-annually, or

annually, the profits of the business are estimated, and a certain percentage of these profits is distributed to the workmen and their managers. Often this distribution of profits is confined to the managers only.

While this is an improvement over the wage system, it violates the eighth law of management—namely, the law of prompt reward. The imagination of the ordinary workman is not enough to maintain his interest in his work at the high pitch necessary to enable him to do his very best. Moreover, any community interest in a commercial enterprise lacks sufficient stimulus. It requires a more direct, personal interest in the outcome to arouse a man to action.

Profit sharing, whether by the payment of profits direct, or in the form of dividends on stock held by the workman, is, at best, only a moderate step in advance of the ordinary wage system so far as the average workman is concerned.

Piece Rate System.—According to the piece rate system, each workman is paid a certain stipulated amount per unit of work done by him. If all managers were fair in their dealings with workmen, and if all workmen were reasonable, the piece rate system would be almost ideal as a method of paying men wherever the work is of a character that admits of measuring individual performance. Due to hoggishness on the part of managers and unreasonableness on the part of workmen, the piece rate system usually fails to accomplish the desired end.

Having established a piece rate of, say, 10 cts. per cu. yd. for shovelling earth into wagons, on the assumption that 16 cu. yds. per day per man is a fair output, it requires more than ordinary foresight and liberality not to cut the rate when laborers begin to load 25 cu. yds. a day. The typical contractor will then begin to reason about as follows: "These men have been soldiering on me in the past. I always thought so; now I know it. Well, now that I do know it, and they know I know it, they will have to work at this rate hereafter or get out. What's more, I am not going to be gouged out of an extra dollar a day, either. If they make 25 cts. extra a day, it's more than they ever got before, and it's all they are entitled to, so we will just drop that 10-ct. rate down to 7 cts. That will satisfy them." But the trouble is that it doesn't. The men immediately become angry, and rightly so. If they do not quit entirely, they lose all further ambition and desire to increase their output, knowing full well that the piece rate will be so cut as to enable them to earn only a slight advance over their original day's wages.

This experience has been so general that nearly all labor unions have put a ban on the piece-rate system. Bear in mind, however, that the piece-rate system is not inherently at fault, and that it is used with great success in many places where the management has been liberal and far-sighted.

On piece-rate work that involves the use of machinery, it is manifest that any improvement in the machinery which enables the men to turn out more units daily, should be accompanied by some reduction in the piece rate. Workmen, however, are usually unrea-

reasonable and oppose any reduction in the rate. This unreasonableness disgusts the manager as much as a manager's boggishness disgusts the workmen. If the manager goes to the expense of buying and operating improved machinery, he is entitled to his share of the increased profit, but the workman is not quick to see things in that light.

Obviously, any piece-rate system is productive of more or less friction between managers and men, yet no system is free from some friction. Probably the chief function of the labor unions of the future will be to protect workmen in agreements with managers, and to be parties in arriving at what those agreements shall be.

The Bonus System.—This system involves paying each workman a daily wage plus a piece rate on each unit in excess of a stipulated minimum. This piece rate on excess product is called a bonus. For example, a laborer receives \$1.50 a day for shoveling earth, and on each cubic yard in excess of 15 cu. yds. shoveled per day he receives a bonus of 7 cts. If he shovels 25 cu. yds., he receives $\$1.50 + (0.07 \times 10) = \2.20 .

The bonus system is really a piece-rate system with a guarantee of a certain minimum wage. Slight though this difference from the piece-rate system is, it is generally viewed with more favor by workmen.

The Differential Piece Rate System.—The principle of this system is to pay a certain piece rate up to a certain output per man, and a higher rate (but still a piece rate) above that output. Applied to drilling, for example, the drill runner would be paid, say, 6 cts. a foot up to a performance of 50 ft. per day, and 8 cts. a foot for every foot above 50. The helper might still be paid \$2 a day straight, but it is wise always to give him also a contingent interest in the result of his work.

The Differential Bonus.—This is based on the same principle as the differential piece rate while guaranteeing to a man a fixed minimum of wages. We have applied it in drilling work, offering the men 2 cts. per foot drilled for every foot above 70, and 3 cts. for every foot above 80 per day, while at the same time paying them their regular rate of wages.

Task Work With a Bonus.—Mr. H. L. Gantt, one of Taylor's pupils, invented a system of differential payment known as "Task Work with a Bonus," which has been very successful in practice and has great flexibility of application under varying conditions. The workman under this system is paid his regular day's wages in any event and a certain lump bonus if he succeeds in accomplishing the standard task. The amount of this bonus is usually about one-third of his regular wages. Mr. Taylor says that this system is especially useful during the difficult and delicate period of transition from the slow pace of ordinary day work to the high speed which is the leading characteristic of good management. During this period of transition in the past, a time was always reached when a sudden leap was taken from improved day work to some form of piece work; and in making this jump many good

men inevitably fell and were lost from the procession. Mr. Gantt's system bridges over this difficult stretch and enables the workman to go smoothly and with gradually accelerating speed from the slower pace of improved day work to the high speed of the new system.

The Premium Plan.—This is the term used by Mr. F. A. Halsey to describe what Mr. Taylor calls the Towne-Halsey system. It is based on the proposition of paying a bonus for achieving an estimated performance, the means to be employed and the methods being left to the ingenuity and initiative of the men, rather than to the management.

Principles Governing the Fixing of a Piece Rate or Bonus.—We are probably well within limits when we say that the average workman engaged on construction work under the wage system is capable of increasing his output 70% if given sufficient incentive to do so, and this without the least physical injury to himself. When it is desired to ascertain how much work men are capable of doing, one of the best plans is to conduct a contest between two or more men, or two or more groups of men, a substantial prize being offered for the best performance. Such a contest should usually extend over several consecutive days, so that it will not be a mere sprint, but a fair endurance test.

If a competitive contest to disclose the workmen's abilities is not practicable, the authors assume that the output probably can be increased 60 to 70% over the output under the wage system, wherever the output depends mainly on the skill and strength of the workmen. In drilling rock, for example, if the average output of each drill is 60 lin. ft. under the wage system, then, in all likelihood, it can be increased to nearly 100 ft. under a bonus system. The driller who receives \$3.00 a day under the wage system is really earning 5 cts. for each of the 60 lin. ft. If it is planned that he shall increase his income 50%, he will receive \$4.50 for the assumed 100 lin. ft. of hole. Hence his piece rate would be $4\frac{1}{2}$ cts. a foot, or his bonus would be \$1.50 on 40 lin. ft. (60 lin. ft. being taken as the standard minimum performance), which is equivalent to a bonus of $3\frac{1}{2}$ cts. per lin. ft. on every foot in excess of 60 ft. to be added to a daily wage of \$3.00. At first sight it seems that the contractor gains only $1\frac{1}{2}$ cts. per lin. ft. for the 40 lin. ft. on which a bonus is paid, or only $\frac{1}{2}$ ct. per lin. ft. on the entire 100 ft. The fact is that the contractor gains much more, not even considering the wages of the driller's helper, for the daily plant charges on the drill remain almost constant, regardless of the output. If fuel, fireman, interest, repairs, depreciation, foreman, etc., are \$4.00 per day per drill, these fixed charges amount to 6.66 cts. per lin. ft. of hole when the output is only 60 lin. ft. a day, as compared with 4 cts. per lin. ft. when the output is 100 ft., or a saving of 2.66 cts. per lin. ft. Wherever a plant of any considerable value is used, it is clear that it would be profitable to double the pay of the workmen if they could double the output of the plant, for the unit saving in plant charges alone would amount to

a handsome profit. This is upon the assumption that the fuel bill remains practically unchanged by the increased output, and it seldom is materially affected by increased output on contract work.

Benefits of the Bonus System.*—Strife develops the best that is in a man, whether it be strength of muscle or the power of the mysterious marrow of the skull.

The evolution of all species and genera, up to man himself, is based upon this law, yet there are millions of misguided men who are striving to abolish strife. They show more pity for the second best in the race than praise for the first. They seem not to see that in the industrial race even the loser wins, and that there is no such thing as being beaten out of "place." A part of the purse goes to everyone that enters.

But there are many kinds of races, and many entries in each. The most popular race, judged by the number of entries, is the slow race. In it you will find men of all classes—clerks, farmers, brick masons, draftsmen, iron workers, and, indeed, the great majority of men working for wages. The one who can make the job last the longest wins. He wears the blue ribbon, and is proud of himself in a sneaking sort of fashion. But the part of the purse for the winner in this race is no greater than for the loser. There is merely the blue ribbon for the prize winners.

Entered in the running race are all men working in competitive businesses. Here are the merchants, manufacturers, contractors, etc.

Then there is the trotting race, not so swift nor so trying, but a contest well worth watching. Here is where careful training counts. This is the race for men educated in the profession of law, medicine, architecture and engineering—each in his class.

What marks the distinction between these three different kinds of runners? Why does the wageworker go slow? Why is the professional man more energetic? Why is the business man the personification of energy? The answer is found in the relative freedom of competition, and the relative size of the prizes to be won.

The wageworker has, from time immemorial, striven to limit competition. In China and India he has succeeded to perfection. There he has developed a system called "caste," which is but a perfected form of our English and American "apprentice system." In India a man belonging to a certain "caste" will swing a wet blanket over you all night to keep you cool; but no amount of money would tempt him to black your shoes or go to the postoffice for your mail. He does not belong to the "caste" that does those things. Hence you must hire ten or a dozen servants if you expect to be served in all your wants. "It makes work," don't you see? It has the slow runner beaten to a standstill.

How can wageworkers be rescued from their own follies, not merely in India, but in America? How can they be induced to enter races for the swift, where the swiftest wins most, but all win more? There is but one, just one, way to bring this end about, and

**Engineering-Contracting*, Feb. 4, 1907.

that is to extend the contract system to individuals and to groups of individuals. When men are paid directly in proportion to what they do, then they DO.

This is the true secret of the economy of performing public work by contract instead of by day labor. And it can be carried a step farther. The contractor can make his men sub-contractors, if he will exercise a little ingenuity and patience in working out a plan for paying them by the piece.

There are many men who are not gifted with the ability to manage workmen where the plain wage system is in use, but who would succeed admirably in getting a big output from men under a bonus or a "piece-work" system. It can be done not only in the field and factory, but in the office, not only where laborers are hired, but where engineers are hired. It is being done with great success in surveying and drafting—two classes of work where the difficulties of applying a bonus or contract system are very great.

When you are told that the bonus system cannot be applied to some particular class of work, because of its unusual nature, place little reliance in the dictum but put your brains at work. Let others enter the race ridden by the jockey Impossible, if they will, but that jockey never bestrode a winner since time began.

Time Cards and Time Books.—Through any stationery store time books can be bought that are ruled and lettered to suit most classes of contract work. The timekeeper enters the name of each man and assigns him a number in the book. On large jobs it is wise also to provide a brass check that can be pinned to the clothing of each workman, so that his number is visible at a glance. The home addresses of common laborers are seldom entered in the time books, but it is desirable always to record home addresses of all men, and particularly the permanent addresses of skilled workmen and foremen. A few postal cards will thus enable one quickly to gather together a gang of skilled men for a new job. It is wise also to have a directory book for entering the names of good foremen, whether they be men that you have employed or not; and a few brief remarks concerning each man's fitness for particular classes of work should be entered. This assists also in identifying men whose names have slipped the memory.

Time books are very often ruled so that the job the men are working on cannot be entered opposite each man's name. It is necessary then to reserve separate pages for each job. Then if a man does several different kinds of work on one job, as many different lines are reserved under his name so that the hours and fractions spent by him on each kind of work can be recorded. In that case the foreman is provided with a time book from which the timekeeper makes abstracts when he goes the rounds.

In order to avoid disputes on pay day, I devised the form of card shown in Fig. 13. Each workman is provided with one of these cards which he keeps until pay day. This card was devised for work on which pay day came every second week. The rate of wages is punched with a conductor's punch, likewise the number of hours and the nearest half hour of each day. The timekeeper or

foreman punches every man's card at the end of the day, and at the same time enters the number of the man and his hours in the time book. If any dispute arises as to the number of hours worked

FIG. 12. Time Card.

the dispute must be settled then and there, for on pay day no claims for extra time will be listened to. This does away entirely with pay day disputes, which is a very satisfactory feature. The

card also serves to check the timekeeper's records. Moreover, it makes "padding" of payrolls more difficult, and facilitates detective work if "padding" is suspected. The card also serves as a discharge slip; for, when a man is discharged, the foreman punches the hours that he has worked and he also punches a hole through the word "discharged." When the man presents the card at the office he is paid; the card is kept as a voucher, and a hole is punched through the word "paid."

Recording Work by Minute Hand Observations.—It has often been said that short time observations prove nothing as to the efficiency of men or machines. This statement has been exceedingly misleading to those who have accepted it as a self-evident truth. When a short time observation does not include the common delays incident to shifting tools, to breakdowns, and the like, it may lead to a serious underestimate of the cost of work. On the other hand, when the so-called short time observation is made long enough to include the time spent in necessary rests, in moving machines, in repairs to plant, and the like, exceedingly valuable results may be obtained. When it is desired to find whether men are lazy, whether a foreman knows his business, whether the method of doing the work can be bettered, or whether the tool or machine is susceptible of improvement, there is no method to be compared with the method of timing work with the minute hand of a watch. Moreover, where it is desired to discover the effect on cost of varying the length of haul, of varying the kind of rock drilled, and the like, timing with the minute hand is the only satisfactory way of arriving at definite conclusions.

If a stop-watch is not available, an ordinary watch with a second hand will serve, and in many classes of work even the second hand can be dispensed with. An example will now be given to illustrate the method and value of a short time observation.

Before beginning the record, set the minute hand so that it points an even minute when the second hand points at 60. Suppose it is desired to time the drilling of a hole in a seamy mica-schist, using a steam drill mounted on a tripod. At 9:37 a. m. the driller is set up and ready to begin drilling a hole and exactly 30 seconds later he turns on the steam; then we begin our record:

9:37:30	Start.
9:49:20	Down.
9:51:20	Start.
10:00:40	Down.
10:03:40	Start.
10:09:40	Down.
10:13:00	Start.
10:14:40	Bit sticks.
10:24:40	After hammering the drill repeatedly, the driller is directed to break up some cast iron and throw it into the drill hole.
10:32:30	Drilling begins again.
10:45:00	Hole finished.
11:15:10	New hole started.

It will be seen that drilling started at 9:37:30, and that at 9:48:30 the full length of the feed screw was out, and that to drill further a new bit had to be inserted. At 9:51:30 the new bit was in and drilling began again, after a delay of 3 mins. in changing bits. At 10:00:40 the second bit was down. Each successive bit, it should be stated, is usually 2 ft. longer than its predecessor. At 10:14:40 the bit sticks in the hole due to having run into a pocket of rotten rock. The observer might readily have predicted this sticking by noting the increased rapidity of penetration; for it took nearly 12 mins. to drill the first 2 ft. of the hole, and only 4 mins. to drill the 2 ft. just prior to the sticking. After wasting 10 mins. abusing the drill the driller finally removed the bit (at the direction of the observer), broke up a piece of cast-iron pipe into hazel nut sizes, and threw two handfuls of the iron into the bottom of the hole. Drilling was resumed at 10:32:30, and the last 2 ft. were completed at 10:45:00. At 11:15:10 the driller started another hole, having spent more than 30 mins. shifting the tripod and drill.

What do we learn from this observation? First that the driller was slow in changing bits; second, that he was very slow in shifting his tripod; third, that the driller was ignorant; fourth, that the foreman was equally so; fifth, that fragments of cast iron completely overcome sticking of bits in this rock.

We know that the driller was slow, because other similar observations have proved it possible to change short bits in much less time than 3 mins., and, since the driller has an easy time of it while turning the crank, he can work rapidly without exhausting himself when it comes to changing bits or shifting the machine. We know that both driller and foreman were ignorant, for broken iron should have been provided ready to use in case of sticking of the bit. We conclude that it will pay to assign a man to measure up the footage of hole drilled by each driller every day, and to offer each driller a bonus for every foot of hole drilled in excess of a stipulated minimum.

The foregoing is a record of fact and not of theory. On a large contract job I secured an increase of 45% in the daily footage of each drill by taking just such observations as the above.

I have found it of great advantage to time in detail the work of cableways, derricks, steam shovels, concrete mixers, dinky locomotives, pile drivers and other machines used on contract work. Even the output of men working with hand tools can be profitably studied in the same way. The number of shovelfuls of earth may be timed under different conditions, with a view to ascertaining the effect of changed conditions, and the effect of using larger shovels. However, the greatest gains from minute-hand timing occur when it is applied to machines operated by power rather than to hand work.

It is desirable in nearly all cases not to let the workmen know that they are being timed. When men are working in the open air, an observer can often use the telescope of a transit or a pair of field glasses to good advantage. In shop work, or underground, where the observer must be near the men, a convenient way of timing any detail of work is by counting. One can soon learn to

count with regularity, and thus dispense with a second or minute hand. Other methods of ascertaining the time of doing work without being observed will occur to anyone who gives thought to the matter.

SECTION II.

EARTH EXCAVATION.

Magnitude of the Subject.—Probably no kind of engineering work involves as many varying factors as earth excavation. Not only is there a wide range of classes of earths but the tools for excavation are almost as varied as the conditions encountered. Taken as a whole, accurate estimating of the cost of earthwork is probably more difficult than estimating the cost of any other item of construction discussed in this book. Having already written one book on earthwork, and having another and much larger treatise in preparation, I shall give in this section only the very briefest summary of some of the commoner methods of earth excavation and cost.

In other sections of this book will be found supplementary data on earthwork, for which consult the index under "Excavation, Earth."

Earth Measurement.—Earthwork is paid for by the cubic yard, and is usually measured "in place," that is, in the natural bank or pit before it has been loosened. The price paid usually includes the excavating, hauling and placing the earth in the embankment, and no extra price is paid for making the embankment—in other words, the earth is paid for but once. Occasionally, in dike work, in building reservoir embankments, and wherever it is very difficult to measure the earth in place, it is specified that the earth shall be measured in the consolidated embankment. However, unless otherwise stated, all costs given in this book refer to measurements of earth in place.

Many specifications for railroad work contain an "overhaul clause," which provides that for all earth hauled more than a certain specified limit, the contractor shall be paid a certain amount per cubic yard, usually 1 ct. per cu. yd. per 100 ft. overhaul. The specified limit of "free haul" is sometimes 1,000 ft., sometimes 500 ft. Even in case of an overhaul, no additional payment is made for building the embankment, but only for the overhaul.

Earth Shrinkage.—Earth when first loosened and shoveled into a wagon swells, that is, it occupies more space than it did "in place"; but, when placed in an embankment and rolled or pounded down, it shrinks, and this shrinkage is often so great that the earth occupies less space in the embankment than it did "in place." The following is a summary, based upon data of actual tests given in my book on earthwork:

1. Taking extreme cases, earth swells when first loosened with

a shovel, so that after loosening it occupies $1\frac{1}{7}$ to $1\frac{1}{2}$ times as much space as it did before loosening; in other words, loose earth is 14% to 50% more bulky than natural bank earth.

2. As an average, we may say that clean sand and gravel swell $1\frac{1}{7}$, or 14% to 15%; loam, loamy sand or gravel swell $1\frac{1}{5}$, or 20%; dense clay, and dense mixtures of gravel and clay, $\frac{1}{2}$ to $\frac{1}{2}$, or 33% to 50%, ordinarily about 35%; while unusually dense gravel and clay banks swell 50%.

3. Loose earth is compacted by several means; (a) the puddling action of water, (b) the pounding of hoofs and wheels, (c) the jarring and compressive action of rolling artificially.

4. If the puddling action of rains is the only factor, a loose mass of earth will shrink slowly back to its original volume, but an embankment of loose earth will at the end of a year be still about $1\frac{1}{12}$, or 8%, greater than the cut it came from.

5. If the embankment is made with small one-horse carts, or wheel scrapers, at the end of the work it will occupy 5 to 10% less space than the cut from which the earth was taken, and in subsequent years will shrink about 2% more, often less than 2%.

6. If the embankment is made with wagons or dump cars, and made rapidly in dry weather without water, it will shrink about 8% to 10% in the year following the completion of the work, and very little in subsequent years.

7. The height of the embankment appears to have little effect on its subsequent shrinkage.

8. By the proper mixing of clay or loam and gravel, followed by sprinkling and rolling in thin layers, a bank can be made weighing $1\frac{1}{2}$ times as much as loose earth, or 133 lbs. per cu. ft.

9. The bottoms of certain rivers, banks of cemented gravel, and hardpan, are more than ordinarily dense, and will occupy more space in the fill than in the cut unless rolled.

Kinds of Earth.—Earth may be divided into three classes as regards difficulty of excavation: (1) Easy earth; (2) average earth; and (3) tough earth. To the first class belong loam, sand, and ordinary gravel, which require little or no picking to loosen ready for shoveling. To the second class belong sands and gravels impregnated with an amount of clay or loam that binds the particles together, making it necessary to use a pick or a plow drawn by two horses to loosen the earth before shoveling. To the third class belong the compact clays, the hardened crusts of old roads, and all earths so hard that one team of horses can pull a plow through the earth only with greatest difficulty, but that two teams of horses on one plow can loosen with comparative ease.

This third class of earth passes by insensible degrees into what is called "hardpan." Hardpan commonly means a very compact clay, or mixture of gravel or boulders with clay. Soft shales that can be plowed with a rooter plow are sometimes called hardpan. There are also certain gravels cemented with an iron oxide (iron rust) which are called hardpan.

There are many local names applied to different kinds of earth.

"Adobe" is a name much used in Texas, Arizona, California and neighboring states to denote any clay of which mud bricks, or adobes, might be made. "Gumbo" is a word used in the Mississippi Valley to denote a black loam containing so much clay as to be exceedingly sticky when wet. "Marl" is, strictly speaking, a mixture of clay and pulverized limestone, but the term is often applied to clay soils containing only 1% to 2% of limestone dust, as, for example, the greensand marls of New Jersey. There are many local deposits of disintegrated minerals, which, when soapy in texture, are often called marl. In some cases these deposits are so greasy that, when saturated with water, slides and cave-ins occur when an attempt is made to excavate them.

Quicksand is a term applied to any sand, or sandy material, which flows like molasses when the sand is saturated with water.

In this book the rules for estimating costs, unless otherwise stated, relate to "average earth," as above defined.

Definitions of Haul and Lead.—"Lead" is a term used to denote the horizontal distance in a straight line from the center of mass of the pit to the center of mass of the dump. The pit, in this case, refers to the volume of earth to be excavated, and the dump refers to the embankment. The "lead" does not include the distance actually traveled, including turnouts, etc., from pit to dump; this actual distance traveled by the cars or wagons is called the "haul." The "haul" is then half the distance traveled by a car or wagon in making a round trip.

Work of Teams.—A "team," as used in this book, means a pair of horses and their driver. Even where the word driver is omitted in speaking of the cost of team work, the wages of the driver are always included under the word "team."

A good average team is capable of traveling 20 miles in 10 hrs., going 10 miles loaded and returning 10 miles empty, over fairly hard earth roads. If the team is traveling constantly over soft ground, 15 miles is a good day's work. On the other hand, if the team is traveling over good gravel or macadam roads, or paved streets, it is possible to average 25 miles per 10-hr. day. These rates include the occasional stops made for rests, etc., and include the climbing of an occasional hill.

When traveling at the rate of $2\frac{1}{2}$ miles an hour, which is the ordinary walking gait of horses, the distance covered in 1 min. is 320 ft. Over good hard roads a team may trot with an empty wagon at the rate of 5 miles per hr., and thus make up for delays in loading and unloading, so as to cover the full 20 miles of daily work; but over soft ground a team should not trot.

The loads that a team can haul (in addition to the weight of the wagon) over different kinds of roads are as follows:

	Short tons.	Earth, cu. yds.
Very poor earth road.....	1.0	0.8
Poor earth road.....	1.25	1.0
Good hard earth road.....	2.0	1.6
Good clean macadam road.....	3.0	2.4

It is not possible to haul much greater loads over an asphalt or

brick pavement than over a first-class, clean macadam. On all the kinds of roads to which the above averages apply, there may be occasional steep grades to ascend, and occasional bad spots to pass over.

The pulling power of a horse averages about one-tenth of his weight when exerted steadily for 10 hrs.; that is, a 1,200-lb. horse will exert an average pull of 120 lbs. on the traces. But for a short space of time the horse can exert a pull (if he has a good foothold) equal to about four-tenths his weight, that is, four times his average all-day pull. This I have tested with teams, not only in ascending steep grades but in lifting the hammer of a horse-operated pile driver.

Where teams are traveling long distances, it is customary to have two wagons keep together, so that one team can help the other up a steep hill by acting as a "snatch team." A "snatch team," or helping team, may often be kept busy to advantage in pulling heavily loaded teams out of a pit, or onto a soft embankment, or up a steep grade. Three-horse snatch teams are frequently used. A small hoisting engine may replace a snatch team to advantage in many places. By laying channel irons for rails up a steep hill, and having a hoisting engine at the top, very heavy loads can be assisted over bad roads. In this case, a boy mounted on a pony can drag the hoisting rope back to the foot of the hill ready for the next team. Plank roads can often be built to advantage for short distances up steep grades, or over bad spots.

In the far West it is customary for three or more teams to be hitched to a train of two or more wagons; and, when a steep hill is to be ascended, to haul one wagon up at a time. This saves wages of drivers.

In the last section of this book, Miscellaneous Costs, will be found further suggestions on hauling with teams, also costs of feeding and maintaining teams. Consult the index under Hauling, Teams.

Cost of Plowing.—A team on a plow will loosen 500 cu. yds. of loam, or 350 cu. yds. of loamy gravel, or 250 cu. yds. of fairly tough clay, per 10-hr. day. For "average earth," therefore assume 350 cu. yds. per day loosened by a team and driver and one man holding plow. With wages at \$3.50 for team and driver, and \$1.50 for laborer, the cost of plowing average earth is 1½ cts. per cu. yd.

In plowing very tough material with a pick-pointed plow, four horses and three men, estimate 180 cu. yds. plowed per day at a cost of 5 cts. per cu. yd.

For tough material there has recently been developed a "gang plow" of remarkable efficiency. It consists of a framework mounted on four small wheels, and equipped with five rooters or plows. These plows can be quickly set, by means of levers, to plow or cut to any desired depth. From 6 to 12 horses, or a traction engine, pull the gang plow, and it cuts five furrows at once. This gang plow is made by the Petrolithic Pavement Co., Los Angeles, Calif.

Cost of Picking and Shoveling.—When wages are \$1.50 per 10-hr.

day, the cost of loosening earth with a pick (instead of a plow) ranges from 1 ct. per cu. yd. for very easy earth, to 11 cts. per cu. yd. for very stiff clay or cemented gravel; for "average earth" the cost of picking is about 4 cts. per cu. yd.

The cost of loosening with a pick and shoveling into wagons is as follows, wages being 15 cts. per hr.:

	Per cu. yd.
Easy earth, light sand or loam.....	12 cts.
Average earth	15 cts.
Tough clay	20 cts.
Hardpan	40 cts.

The amount of earth that a man can load with a shovel varies with the character of the earth, the way it has been loosened, the size and shape of the shovel, etc. If a man is shoveling earth from the face of a cut that has been undermined and broken down with picks, he can readily load 18 cu. yds. per 10-hr. day, after the earth has been loosened. If he is shoveling plowed earth, where he must use more force in driving the shovel into the soil, he will easily load 14 cu. yds. of average earth in 10 hrs. If he is shoveling loose earth off boards upon which it has been dumped, he can load 25 cu. yds. in 10 hrs., but it is not wise to count on more than 20 cu. yds. even under good foremanship.

For data on the cost of trenching, the reader is referred to the sections on Sewers and on Water-works. Consult the index under "Excavating, Trenches."

Cost of Trimming, Rolling, Etc.—After earth has been dumped from carts or wagons, a man will spread in 6-in. layers by hand 75 cu. yds. in 10 hrs., at a cost of 2 cts. per cu. yd. A leveling scraper, or road machine, will spread large quantities of earth for $\frac{1}{2}$ ct. to $\frac{3}{4}$ ct. per cu. yd. With a leveling scraper operated by a team and driver and a helper, I have had 500 cu. yds. spread per day. A road machine, operated by 6 horses and 2 men, will spread 900 cu. yds. in 10 hrs. in 6-in. layers, earth having been dumped from patent dump-wagons.

A man can thoroughly tamp 25 cu. yds., in 6-in. layers, per 10-hr. day at 6 cts. per cu. yd. Embankments can be consolidated with horse-drawn rollers for $\frac{1}{2}$ to 1 ct. per cu. yd., wages of a team being \$1.50 a day. I have one record of 4 cts. per cu. yd. (at the above wages), for rolling a reservoir embankment, but the work was not well handled.

The cost of sprinkling embankments, if specified, is difficult to estimate because of the vagueness of specifications. However, more than 8 cu. ft. of water per cu. yd. of earth, is seldom required.

On a large embankment three sprinkling carts, each drawn by three teams, with one driver, sprinkled 1,000 cu. yds. of earth per day of 10 hrs., with short haul. Such carts each held 150 cu. ft. of water weighing $4\frac{1}{2}$ tons, which is an exceedingly large capacity. A sprinkler of this size can be loaded from a tank in 15 mins., and emptied in the same length of time. Knowing the length of haul and speed of team the cost of sprinkling is readily determined. In

the case just given the cost was $2\frac{1}{4}$ cts. per cu. yd. of earth for sprinkling and about 5 cu. ft. of water per cu. yd. were used.

From several careful observations the writer has found that a gang of men under a good foreman will each trim the sod and humps off the hard surface of a cut to the depth of 1 or $1\frac{1}{2}$ ins. at the rate of 200 sq. ft. or 22 sq. yds. per hour, at a cost of $\frac{2}{5}$ ct. per sq. yd.; and where there was no sod to remove, the soil being sandy loam, the cost was one-half as much or $\frac{1}{5}$ ct. per sq. yd. Massachusetts contractors bid almost uniformly $2\frac{1}{2}$ cts. a sq. yd. for "surfacing" (wages 17 cts. per hour), which includes rolling the finished surface with steam roller.

A roadway, including ditches, 36 ft. wide and a mile long, has 21,000 sq. yds. of surface, which at $\frac{1}{2}$ ct. is \$140, actual cost of trimming. If the total excavation in a mile is 3,500 cu. yds. (which is about the average in N. Y. State), the cost of trimming, distributed over this 3,500 cu. yds., is 4 cts. per cu. yd. of excavation, a cost much greater than a mere guess would lead one to suppose.

I have directed the scraping of a light growth of weeds and grass off the 4-ft. shoulder of a road by going once over it with a leveling scraper, at a rate of 200 sq. yds. per hour, or ten times faster than a man with a mattock would have done it; making the actual cost about $\frac{1}{4}$ ct. per sq. yd. where the team, driver and helpers' wages were 50 cts. per hour.

Cost of Wheelbarrow Work.—A man wheeling a barrow over run-plank can not be counted on to travel more than 15 miles per 10-hr. day. If the runway is level a load of 300 lbs. or more may be wheeled in a barrow, but it is not safe to count upon more than 250 lbs., or $1/10$ cu. yd. of earth. This is for good level runways, but, as most wheelbarrow work involves ascending steep grades, estimate $1/14$ to $1/15$ cu. yd. per barrow load. With wages at 15 cts. per hr., the cost of wheeling earth in barrows is, therefore, 5 cts. per cu. yd., per 100 ft. of haul, the haul being the distance from pit to dump. If the runways were level, and the men worked hard, the cost might be reduced to 3 cts. per cu. yd. per 100 ft. of haul.

The cost of picking and loading has already been given, and may be assumed to be 15 cts. per cu. yd. A wheelbarrow is dumped in about $\frac{1}{4}$ min., which is equivalent to a loss of nearly 4 mins. per cu. yd., where 15 barrow loads make a yard; and this is equivalent to 1 ct. per cu. yd. for dumping the barrows. The time lost in changing barrows, etc., may easily add another 1 ct. per cu. yd. The rule for estimating the cost of loosening, loading and hauling average earth in barrows is as follows when wages are 15 cts. per hr.:

Rule I.—To a fixed cost of 17 cts. per cu. yd., add 5 cts. per cu. yd. per 100 ft. haul, when steep ascents must be made, or $2\frac{1}{2}$ cts. per 100 ft. when level.

Cost by One-Horse Carts.—Small two-wheeled carts drawn by one horse are often used on railway work. If the haul is level or slightly down hill and over a well compacted embankment, a horse

will pull 0.6 cu. yd. per load; but over poor earth roads it is not safe to count upon more than 0.4 cu. yd. per load, if there are any steep grades to ascend. On short hauls of 200 ft. or less, one driver can tend to two carts by leading one to the dump while the other is being loaded. A gang of 4 or 5 men should load a cart with 0.4 cu. yd. in 3 mins., and it takes about 1 min. to dump a cart, so that 4 mins. of cart time are "lost" every round trip. If the wages of a horse are \$1 per 10-hr. day, and the wages of a driver are \$1.50 a day, the wages of a cart and half a driver are \$1.75 a day. The 4 mins. "lost time" is therefore equivalent to 3 cts. per cu. yd. The cost of picking and loading average earth is about 15 cts. per cu. yd., as previously given. A dumpman can easily dump a cart load a minute, where he has no spreading to do; but the material is seldom delivered fast enough. If we assume 150 cu. yds. delivered to him in carts in 10 hrs., the cost is 1 ct. per cu. yd. for dumpman's wages. Hence the total fixed cost may be assumed as 15 + 3 + 1 ct., or 19 cts. per cu. yd. If the cart load is 0.4 cu. yd., and wages are as above given, we have the following rule:

Rule II.—To a fixed cost of 19 cts. per cu. yd. add $\frac{1}{2}$ ct. per cu. yd. per 100 ft. of haul.

If the material is plowed, and is shoveled easily, the fixed cost may become 14 cts. per cu. yd. instead of 19 cts.

If the haul is long, one driver may still attend to two carts by taking them both together to the dump. There are occasions, however, when one driver attends to only one cart; in such cases the cost of hauling is 1 ct. per cu. yd. per 100 ft.

In cities, where the carts travel over hard earth or gravel roads, a cart carrying $\frac{1}{2}$ cu. yd. may be used. The cost of hauling is, then, $\frac{1}{2}$ ct. per cu. yd. per 100 ft. haul, wages of cart and driver being 25 cts. per hour.

Cost by Wagons.—There are three types of four-wheeled wagons commonly used by contractors: (1) The flat-bottom wagon; (2) the bottom-dump wagon; and (3) the end-dump wagon. Any farmer's wagon can be made into a flat-bottom wagon by removing the wagon box and replacing it with "slats" of 3 x 6-in. sticks for a bottom, and 2 x 12-in., or 2 x 16-in., planks for sides and ends. The bottom-dump, or "patent dump-wagon," has a bottom consisting of two doors that swing downward in dumping.

The end-dump wagon dumps backward like a two-wheeled cart. The best makes of this type of wagon are provided with a geared device by which the dumpman slides the wagon box bodily backward over the axle of the rear wheels until it tips and dumps its load.

The loads that are commonly hauled in a wagon by one team are given on page 121.

To reduce the lost time in loading wagons a common expedient is to provide extra wagons which are loaded while the teams are on the road to and from the dump. A team can be changed from an empty wagon to a loaded wagon in 1 to 1½ mins.

Three horses should be used on each wagon far oftener than they

are used on contract work, as nearly 50% more material can be hauled per load than with two horses. In the far West, one often sees two teams (four horses) hitched to a wagon, even on short haul work.

One man aided by the driver can dump a flat-bottom wagon holding 0.8 cu. yd. in $1\frac{1}{2}$ mins., at a cost of 0.4 ct. per cu. yd. for the dumpman's time and 1 ct. per cu. yd. for lost time of team, wages being 15 cts. per hr. for dumpman, and 35 cts. per hr. for the team. It takes 3 mins. for these men to dump a large flat-bottom wagon holding $1\frac{1}{2}$ cu. yds., where the driver removes the seat before dumping and replaces it afterward. So that in either case we see that the cost of dumping is about $1\frac{1}{2}$ cts. per cu. yd. If a binder chain is wound around the wagon box to hold the slats close together so that no earth will spill through onto a street pavement, it takes 5 mins. to dump the wagon.

The time required to dump a drop-bottom wagon is practically nominal, and the driver dumps his own wagon.

It takes about 1 min. for the dumpman and driver to dump an end-dump wagon.

In loading wagons there are usually enough men provided in the pit to load 1 cu. yd. into a wagon in 4 or 5 mins. or less. This is equivalent to $2\frac{1}{2}$ to 3 cts. per cu. yd. for lost team time in the pit, which, added to the lost team time at the dump, gives us about 4 cts. per cu. yd. where flat-bottom wagons are used. The cost of the dumpman's time will never be much less than $\frac{1}{2}$ ct. per cu. yd.; and, if the material is not delivered rapidly, it may be much more.

The cost of excavating and loading has been given in previous pages. We assume this cost to average 13 cts. per cu. yd., where the earth is plowed, and add 5 cts. for lost team time and dumping, we have a fixed cost of 18 cts. per cu. yd. Then the cost of hauling will depend upon the size of the load, and, assuming wages of team at 35 cts. per hr., and speed of travel $2\frac{1}{2}$ miles an hour while actually walking, we have the following rule:

Rule III.—To a fixed cost of 18 cts. per cu. yd., add $\frac{1}{2}$ ct. per cu. yd. per 100 ft. haul when the wagon load is 1 cu. yd.

For other wagon loads use the following:

	Per cu. yd. per 100 ft.
Load being 0.8 cu. yd., add.....	0.66 ct.
Load being 1.0 cu. yd., add.....	0.53 ct.
Load being 1.6 cu. yd., add.....	0.33 ct.
Load being 2.0 cu. yds., add.....	0.26 ct.
Load being 2.4 cu. yds., add.....	0.22 ct.

In round numbers, therefore, for a load of 1 cu. yd. we must add $\frac{1}{2}$ ct. per cu. yd. per 100 ft. haul, or 28 cts. per cu. yd. per mile haul, wages of team being 35 cts. per hr.

Cost by Drag Scrapers.—A drag scraper, or slip scraper, is a steel scoop, not mounted on wheels, for scooping up and transporting earth short distances, and is drawn by a team. The ordinary No 2 drag scraper weighs 100 lbs., and is listed in catalogues as holding 5 cu. ft. of earth. The actual average load, however, is about 1-3 to 1-7 cu. yd. place measure.

In working drag scrapers on short leads there are usually three

teams traveling in a circle or ellipse of 150 ft. circumference. One man loads the scrapers in the pit as they go by, and each driver dumps his own scraper. When the gang is working properly, the actual speed of the teams is $2\frac{1}{2}$ miles an hour, or 220 ft. per min., while actually walking; and the "lost time" in loading and dumping is $\frac{1}{2}$ to $\frac{3}{4}$ min. per trip, or, say, $2\frac{1}{2}$ min. per cu. yd., which is equivalent to 2 cts. per cu. yd. for lost team time when team wages are 35 cts. per hr. The man loading can readily load 1,500 scrapers per day, or, say, 180 cu. yds., so that the cost of loading is about $\frac{1}{2}$ ct. per cu. yd. The cost of plowing (see page 122) will average $1\frac{1}{2}$ cts. per cu. yd. As above stated, the teams travel in a circle, and, no matter how short the "lead," room must be allowed for turning and manoeuvring the teams; this room is approximately 50 ft. at each end of the haul, so that we have 100 ft. of extra travel, or nearly $\frac{1}{2}$ min. of time for each trip, in addition to the "lead." This $\frac{1}{2}$ min. adds another 2 cts. per cu. yd. Summing up, we have the following fixed cost, exclusive of foreman's wages:

	Per cu. yd.
Lost team time loading and dumping.....	2 cts.
Wages of man loading.....	$\frac{1}{2}$ cts.
Plowing	$1\frac{1}{2}$ cts.
Extra travel of team in turning, etc.....	2 cts.
Total fixed cost.....	$6\frac{1}{4}$ cts.

If the average load is 1-7 cu. yd., hauled at a speed of 220 ft. per min., the cost of hauling is $4\frac{1}{2}$ cts. per cu. yd. per 100 ft. of "lead." Note that this "lead" is measured on a straight line from center of pit to center of dump. The rule, then, is as follows for "average earth" when team wages are 35 cts. per hr.:

Rule IV.—To a fixed cost of $6\frac{1}{4}$ cts. per cu. yd. add $4\frac{1}{2}$ cts. per cu. yd. per 100 ft. of "lead."

This is approximately equivalent to 1 ct. added for each 25 ft. of "lead." Thus, if the "lead" is 25 ft., the cost of drag scraper work is $6\frac{1}{4} + 1$, or $7\frac{1}{4}$ cts. per cu. yd.

The cost of foreman's wages is ordinarily about $\frac{1}{4}$ ct. per cu. yd., and wear on scrapers, etc., will add another $\frac{1}{4}$ ct. per cu. yd.

The cost of excavating and hauling fairly stiff clay may easily be 30% more than the above costs for "average earth."

Cost by Wheel Scrapers.—The wheel scraper is a development of the drag scraper, being a steel scoop low hung between two wheels. The following are common sizes of wheelers:

	Weight, lbs.	Capacity.	
		Listed, cu. ft.	Actual Struck Measure, cu. ft.
No. 1	340—450	9—10	$7\frac{1}{2}$ —9
No. 2	475—500	12—13	$8\frac{1}{2}$
No. $2\frac{1}{2}$	575	14	12
No. 3	625—800	16—17	$15\frac{1}{2}$

The "listed" capacity is the capacity given in catalogs. The "actual struck measure" capacity is the exact contents of the bowl when level full of loose earth, and it should be remembered that

about one-fifth of 20% should be deducted from this to get the actual struck capacity of earth measured "in place" before loosening.

Large wheelers, even in light soils, and small wheelers in tough soils, seldom leave the pit full of earth, but at the back end of the bowl there is usually a wedge-shaped unfilled space. I have found the average load, "place measure," carried by wheelers is as follows:

No. 1	1/5 cu. yd.
No. 2	1/4 cu. yd.
No. 2 1/2	1/2 cu. yd.
No. 3	4/10 cu. yd.

A snatch team, to assist in loading, is generally used with a No. 2 wheeler, and always with a No. 3 wheeler.

On long hauls it is advisable to have men with shovels to heap the bowl full of earth, using a front gate on the wheeler to prevent loss of material in transit.

The lightest No. 1 wheelers made are to be recommended where leads are very short and rises steep, that is, wherever drag scrapers are ordinarily used, for they move earth more economically than drags. Where soil is very stony, or full of roots, drag scrapers are to be preferred, since they are more easily and quickly loaded under such conditions. With wheelers, as with drag scrapers, add 50 ft. to the actual "lead" for turning and maneuvering the teams, equivalent to half minute of team time each trip. Another half minute is lost in loading and dumping.

The fixed costs for the three common sizes of wheelers are as follows for "average earth," when wages are 15 cts. per hr. for laborer and 35 cts. per hr. for team (with driver):

	—Cents per cu. yd.—		
	No. 1.	No. 2.	No. 3.
Lost team time loading and dumping....	1.5	1.2	0.8
Wages of man loading	0.8	0.8	1.5
Plowing	1.5	1.5	1.5
Extra travel of team in turning, etc.....	1.5	1.2	0.7
Snatch team	1.5	1.5
Wages of man dumping.....	0.8
Total, cts. per cu. yd.....	5.3	6.2	6.8
Size of load hauled, cu. yds.....	1/5	1/4	4/10

A snatch team is usually used with No. 2 wheelers, and in short-haul work there is usually a dump man also.

In easy soils, I have had one snatch team assist in loading 300 cu. yds. per day, so that this item may be less than above estimated; and under the same conditions another 1/2 ct. per cu. yd. or more may be saved in wages of men loading and dumping. There are usually two men required to load a No. 3 wheeler, which accounts for the higher cost of this item in the No. 3 column.

The cost of wheeler work, based upon the foregoing data, is as follows:

Rule V.—To a fixed cost of 5 1/4 cts. per cu. yd. for No. 1

wheelers, or $6\frac{1}{4}$ cts. for No. 2 wheelers, or $4\frac{3}{4}$ cts. for No. 3 wheelers, add the following per cu. yd. per 100 ft. of "lead": $2\frac{1}{2}$ cts. for No. 1 wheelers; or $2\frac{1}{5}$ cts. for No. 2 wheelers; or $1\frac{1}{2}$ cts. for No. 3 wheelers.

The cost of foreman's wages and repair of wheelers will add about 1 ct. more per cu. yd.

If the "lead" is 50 ft. and No. 1 wheelers are used, the cost is $5\frac{1}{4}$ cts. + ($\frac{1}{2} \times 2\frac{1}{2}$ cts.), or 6.7 cts. per cu. yd., exclusive of foreman's wages.

Cost by Fresno Scrapers.—The ordinary four-horse fresno scraper has a bowl 13 ins. high, 18-ins. wide and 5 ft. long, giving a struck measure capacity of slightly more than 8 cu. ft.; but in almost any soil, except dry, running sand, the earth will heap up 6 or 8 ins. above the top of the bowl, and will extend quite a distance beyond the front of the bowl. One carefully measured fresno load of clayey earth contained 19 cu. ft. of loose earth, which compacted to $16\frac{1}{4}$ cu. ft. when rammed in 4-in. layers in a box. Several other large loads gave almost the same results after being hauled 100 ft. over a level road.

Mr. Geo. J. Specht has stated that on a down hill haul, loads will average 35 cu. ft. and occasionally run as high as 44 cu. ft. However, this could only occur with light, damp soil and on a down hill pull where much material could be drifted ahead of the fresno scraper. I have never measured any loads of that size.

On level hauls, or on uphill pulls, it is not ordinarily safe to count on more than $\frac{1}{2}$ cu. yd. (measured in cut) per load, although under favorable conditions the average load may be 25 to 50 per cent greater, while under unfavorable conditions it may be 25 per cent less.

If the delays in loading and dumping are excluded, the team can be counted upon to travel about 200 ft. per minute. It requires some room in which to maneuver scrapers of any kind, no matter what method of hauling the teams is adopted. Hence one must not measure the average distance in a straight line from center of the cut to the center of the fill, and call that the average haul, for that is the average "lead," which is considerably shorter than the actual haul.

When the daily wage of a driver is \$1.50 and that of each of the four horses is \$1, a total of \$5.50 per fresno, the following rule will give the average cost of fresno work, not including plowing, trimming or supervision.

Rule VI.—To a fixed cost of 5 cts. per cu. yd. add $1\frac{1}{4}$ cts. per 100 ft. of "lead."

The fixed cost of 5 cts. includes traveling the extra distance in loading, etc., the slower speed in loading, the shifting of the gang to newly plowed ground, etc., and it includes 1 ct. for plowing the earth. The hauling cost of $1\frac{1}{4}$ cts. per 100 ft. is based upon a traveling speed of 200 ft. per minute (when not delayed by loading, dumping, etc.) and upon the assumption that the average load is

$\frac{1}{2}$ cu. yd., wages of four horses and driver being \$6 per 10-hr. day. In applying the rule never assume a "lead" shorter than 50 ft.

"Lead" in feet.	Cu. yds. per fresno per day.
50	120
100	100
150	87
200	78
250	67
300	60
350	55
400	50

I have never measured any fresno loads that had been hauled as far as 400 ft., and I doubt very much whether fresno loads hauled that distance would average as much as $\frac{1}{2}$ cu. yd., due to the loss that occurs en route.

If the soil is not of a kind that heaps up and drifts well in front of the fresno, the average load will probably not exceed 9 cu. ft. or $\frac{1}{8}$ cu. yd., particularly on long hauls. In which case the rule becomes:

Rule VII.—To a fixed cost of 5 cts. per cu. yd. add $2\frac{1}{2}$ cts. for each 100 ft. of "lead."

Then, for a 500-ft. "lead" the cost would be $5 + (5 \times 2\frac{1}{2})$, or 21 cts. per cu. yd. This checks very closely with Mr. Walter N. Frickstad's data for a 500-ft. haul with fresnos, as given in *Engineering-Contracting*, Nov. 3, 1909.

Based upon this last rule the cost of fresno work is as follows for different leads:

"Lead" in feet.	Cts. per cu yd.	Cu. yds. per fresno per day.
50	$5\frac{1}{2}$	109
100	7	86
150	$8\frac{1}{2}$	70
200	10	60
250	$11\frac{1}{2}$	52
300	13	46
400	16	37
500	19	31
600	22	28

Bear in mind that the above costs do not include cost of foreman's wages, which ordinarily ranges from $\frac{1}{2}$ to 1 ct. per cu. yd. Dressing roadbed and slopes will usually cost an additional $\frac{1}{2}$ ct. per sq. yd. of surface trimmed.

I have assumed a 10-hr. working day, but it is my opinion that it makes little difference whether the day is 8 or 10 hrs. long, for the horses can be "crowded" harder on the shorter day, and thus cover the same mileage as on the longer day.

I have assumed that each fresno is loaded as well as dumped by the driver. This is one of the great advantages of a fresno over a drag scraper. However, in tough soils it is generally wise to have one man with each string of fresnos to load them.

A four-horse fresno scraper weighs about 275 lbs. A rope should be tied to the end of the handle, so that the driver can jerk the rope

and right the bowl when he gets back to the pit and is ready to load.

The four horses are hitched abreast. The two outside horses have a "jockey stick," the ends of which are tied to their bits, and each horse's bridle is fastened to the adjoining horse's bridle by a short strap or rawhide string. Each of the two reins is divided into two lines, one line going to each horse's bridle, one of the lines from each rein going to one outside horse, and the other line to the second outside horse from it. Thus the left hand rein pulls the left hand outside horse and the right hand inside horse, these two horses guiding the other two horses by the bit straps. The right hand rein controls the other two horses.

Due to the fact that fresno scrapers can ordinarily be loaded by the drivers, it is not necessary to work several fresnos in a string. In fact when building an embankment from two ditches, one on each side, a common method of handling the fresnos is as follows: The driver loads the fresno in the ditch, drives up the embankment diagonally, dumps the load and continues right across the embankment and down into the ditch on the opposite side, where he loads again after turning around, and returns. When working in this fashion, some foremen require all the fresnos to move in unison, so that a glance will show that none is loafing. When handled thus, however, it is not possible to plow where the fresnos are working, so some time is always lost in moving the fresno gang to newly plowed ground. This lost time has been allowed for in the rule for cost above given.

Fresno work is cheaper than drag scraper work under almost every condition that can be named.

It is not easy to fix the limit of economic haul with fresnos as compared with wheeled scrapers, principally because the size of the fresno load varies greatly in different soils. It is quite commonly believed in California that for hauls beyond 200 to 250 ft. the wheeled scraper is preferable, but in tough soils or in dry sand the fresno loads may be so small that a wheeler can compete successfully on shorter hauls. On the other hand, in soft, damp soils that heap up and drift well in front of a fresno, the economic haul may considerably exceed 300 ft.

The above conclusions are based upon the assumption that the wage of the driver equals the wage of two horses. Where horse feed is cheap and wages of men are high, it is clear that the fresno shows up more favorably, for it is one of the characteristics of fresno work that there are many horses and comparatively few men.

In solving the problem of economic earthwork in any individual case, the first step should be to measure a number of average loads of earth as they are delivered at the dump by fresnos and by wheelers. Don't measure the loads in the ditch or pit, but on the dump, for much may be lost in transit. Shovel the load of earth into a wooden box and ram it in 4 to 6-in. layers. A little time spent in thus measuring the loads accurately will enable a close estimate to be made of the actual yardage moved per day per scraper of each class, provided a boy or man is assigned for a day to the

task of tallying every load moved by a typical fresno gang and by a typical wheeler gang.

Considering the amount of money that is usually at stake, it is remarkable how often guesswork prevails where a little time spent in measuring a few loads and a day's tally of the loads would settle the matter definitely. Where a gang is moving only 1,000 cu. yds. daily, 1 ct. saved per yard means \$10 a day. Yet even the most skilled foreman will find it next to impossible to ascertain the difference of a cent a yard cost between a fresno gang and a wheeler gang merely by looking at them work. I am speaking now of work by these two types of scrapers where the length of haul is such that they are almost on a parity as regards cost. Of course there are hauls where there can be no doubt at all, where it is either the fresno "hands down," or where it is the wheeler "hands down."

Cost by Elevating Graders.—An elevation grader consists essentially of a four-wheeled truck provided with a plow which casts its furrow upon an endless belt, which elevates the material and deposits it in wagons as fast as they are driven under the belt. For successful operation there must be few boulders or roots to stop the plow of the machine; and there must be considerable room in which to turn the machine, and maneuver the teams going and coming, and the ground on which the grader is working must not be too hilly. The machine does not work to advantage in narrow cuts, due to lack of room for wagons alongside. The machine is adapted to loading wagons on road work, but is especially suitable for reservoir work and the like. The machine is used in prairie soils for digging ditches and conveying the material directly into the road, but the material must afterward be leveled with a leveling scraper or road machine; and it would seem better practice to use the road scraper entirely for this class of grading without resort to the elevating grader at all. Claims have been made that 1,000 cu. yds. in 10 hrs. are loaded by the grader. Under very favorable conditions this may be done, but I have never seen a daily average of more than 500 cu. yds. place measure loaded by a grader operating in easy soil.

A grader costs about \$1,000, and is hauled either by 10 or 12 horses or by a 25-hp. traction engine, the latter being usually the more economical in the long run. It requires 3 men to operate the grader, and, where horses are used, 2 or 3 men to drive the horses. Where a traction engine is used, 2 men operate the grader, 1 engine-man operates the traction engine, and it is often necessary to keep a team busy part of the time hauling water for the engine, if water is not supplied by gravity or by pumps. The traction engine burns 0.6 to 0.7 ton, or 1,200 to 1,400 lbs., per 10 hrs. To furnish steam there will be required not over 8 lbs. of water per lb. of coal, or $0.7 \times 8 = 5.6$ tons of water per day. The grader travels about 150 ft. per min. when hauled by an engine, and it takes $1\frac{1}{2}$ mins. to turn around at each end of its run, describing a circle of about 50 ft. diameter in turning. It takes about 15 seconds to load a wagon with $\frac{1}{2}$ cu. yd. of earth measured in

place, when the grader is traveling 150 ft. per min., so that the grader travels 40 ft. in loading a $\frac{3}{4}$ -yd. wagon; then it stops for about 15 sec. until the next wagon comes up under the belt. If three-horse patent dump wagons are used—and no other kind should be used with elevating graders—the wagon load is $1\frac{1}{2}$ cu. yds., and the grader travels about 65 ft. to load a wagon.

I have seen 700 two-horse wagons, holding $\frac{3}{4}$ cu. yd. each, loaded per 10-hr. day; and, I am informed, that with good management and an easy soil, 700 wagons, holding more than 1 cu. yd. each, can be loaded per 10-hr. day. With three-horse wagons the average 10-hr. day's output on the Chicago Drainage Canal was 500 cu. yds. of top soil.

Mr. N. Adelbert Brown, C. E., of Rochester, informs me that an elevating grader was used by Thomas Hollihan, in grading streets at Canandaigua, N. Y. The streets were 60 to 75 ft. wide between property lines, and 36 ft. between curbs. A traction engine was used to haul the grader, and there was no trouble in turning the engine and grader between the walk lines, which was easily within 50 ft. of space. "The efficiency of the machine was not tested fully, due to a lack of teams; but, when teams were available, 50 wagon loads, of $1\frac{1}{2}$ cu. yds. each, were readily loaded in an hour. The machine was satisfactory in stone and gravel roads and stiff clay, but in light sand in some cases refused to elevate." This latter is true, however, of all elevating graders in any dry sand that will not turn a furrow.

Fred. T. Ley & Co., of Springfield, Mass., inform me that elevating graders were used by them on electric railway work in central New York state, both with traction engines and with horses. They averaged 400 to 500 cu. yds. loaded into wagons per grader per day.

No matter how short the lead, a team hauling earth from a grader must perform a large percentage of waste labor following the grader, and this is equivalent to adding about 400 ft. to the "lead." If 2 horses and a driver are worth \$4.50 a day, and the load is $1\frac{1}{2}$ cu. yds., the cost of hauling is 0.6 ct. per cu. yd. per 100 ft. of haul; so that the waste distance traveled (400 ft. lead) adds $2\frac{1}{2}$ cts. per cu. yd. to the cost. With wages of single horses at \$1, and men at \$1.50, the fixed cost is as follows, with an output of 500 cu. yds. per 10 hrs.:

	Per cu. yd.
Lost team time (400 ft. added to "lead").....	2.5 cts.
10 horses on grader and 4 men.....	3.5 "
5 men on dump spreading.....	1.5 "
Interest, repairs and depreciation, \$5 per day....	1.0 "
Total	8.5 cts.

The rule is:

Rule VIII.—To a fixed cost of $8\frac{1}{2}$ cts. add 6/10 ct. per cu. yd. per 100 ft. of lead.

It will take 6 three-horse wagons to handle the 500 cu. yds. per day where the lead is 500 ft.

It is necessary to spread the earth on the dump to prevent stall-

ing of the dump wagons, but by using a leveling scraper the cost of this item can be reduced to 1 ct. or less, instead of the $1\frac{1}{2}$ cts. above given for hand work.

A traction-engine outfit will reduce the cost of operating the grader somewhat below the above given figures, thus:

	Per day.
$\frac{3}{4}$ ton coal, at \$3.....	\$ 2.00
1 engineman	2.00
2 grader operators	5.00
Interest, repairs and depreciation of engine.....	3.50
Total, 500 cu. yds., at 2.7 cts.....	\$13.50

This 2.7 cts. per cu. yd., it will be seen, is 0.8 ct. less than where 10 horses and 4 men operate the grader.

If it is necessary to pump water by hand and haul it far for the traction engine, the cost may easily be increased $\frac{1}{2}$ ct. per cu. yd., or more.

In *Engineering-Contracting*, April, 1906, page 102, etc., there is an article by Mr. Daniel J. Hauer, giving costs of elevating grader work on 7 railroad jobs. The limitations of the grader for narrow thorough cuts are well shown. The average cost was as follows for an average "lead" of 800 ft., with an average daily output of 288 cu. yds. per elevating grader:

	Per cu. yd.
Loading	\$0.100
Hauling	0.127
Dumping and spreading	0.029
Water boy	0.002
Foreman	0.010
Total	\$0.268

The wages of the grader operators were \$1.50 per 10-hr. day; laborers, \$1.50; two-horse team and driver, \$4.60; three-horse team and driver, \$6.25. The \$0.268 does not include any allowance for interest, repairs and depreciation. This is probably as high a cost for elevating grader work as will be likely to occur with the same length of haul and the same rates of wages.

Steam Shovel Data.—The size of a steam shovel is usually denoted by the capacity of the dipper in cubic yards and the weight of the whole machine in tons; both should be given, for in a hard material a smaller dipper is used than in soft material when working with the same steam shovel. The following are some of the standard sizes:

Weight, tons	35	45	55	65	75	90
Dipper, cu. yds.....	$1\frac{1}{4}$	$1\frac{1}{2}$	$1\frac{3}{4}$	2	$2\frac{1}{4}$	3
Coal in 10 hrs., tons.....	$\frac{5}{8}$	1	$1\frac{1}{4}$	$1\frac{1}{2}$	2	$2\frac{1}{2}$
Water in 10 hrs., gala....	1,500	2,000	2,500	3,000	4,000	4,500

The price of shovels is approximately \$130 per ton for the larger sizes, and \$160 per ton for the 35-ton size.

A shovel of any size is so designed that, when digging in average earth, it can average at least 3 dipperfuls per minute, when the dipper arm swings only 90°. Shovels are built to run on standard gage track, and in operating a shovel it is customary to use rails in 6-ft. lengths, so that the shovel cuts 6 ft. into a face before it is

shifted ahead. The time required to shift ahead may average as low as 3 mins., and should never average more than 5 mins., but on poorly managed work I have often seen 10 mins. consumed in shifting the shovel ahead.

"Traction shovels" weighing 25 tons, or less, may be had, and they do not require rails to run upon, but are provided with broad-tired traction wheels.

Steam shovels of small size, mounted like a locomotive crane so that they can swing a full circle, are especially adapted for loading wagons in confined places.

The width of the cut or "swath" excavated by a shovel varies from 18 ft. for the smallest shovels to 40 ft. for the largest. The height of the face of the cut is usually 15 to 30 ft. In tough material the face of the cut should not be higher than the dipper can reach, that is, 14 to 20 ft. Too high a face is treacherous, sliding material is to be avoided, for the shovel may be buried by a slide.

The height of the face of the cut has a marked influence upon the output of a shovel. If the face is only 6 ft. high and 18 ft. wide, there are only 4 cu. yds. per lineal foot of cut, or 20 cu. yds. for every 5 lin. ft. of cut. A 1-yd. shovel would excavate this in, say, 10 mins.; then, if 5 mins. were spent moving forward for the next "bite," there would be 15 mins. required to excavate 20 cu. yds., and one-third of the time would be spent in shifting the shovel. Shallow cuts are expensive not only on this account, but because a full dipper cannot be averaged when the height of the face of the cut becomes much less than one and a half or two times the depth of the bucket.

In addition to the lost time of shifting the shovel, there is more or less lost time switching cars up to the shovel. On "thorough cut" work this lost time of switching is greater than on "side cut" work. A "thorough cut" is practically a huge trench, in which the shovel is working at the face, so that only one or two cars can come up on the track alongside of the shovel, the car track being in the bottom of the cut. This method of attack should be avoided wherever possible. In "side cut" work a full train of cars can come alongside the shovel, one car being loaded after another until the train is loaded.

There are frequently conditions that make it cheaper in the end to use wagons instead of cars for hauling the earth away. In such cases never use a large dipper, for so much earth will spill over the sides of the wagon as to block the road and delay the movement of the wagons, even when a snatch team is used. A 1½-yd. bucket is as large as should be used for loading wagons.

Hauling With Dinkeys.—The ordinary "contractor's locomotive," or "dinkey," travels on a track of 3-ft. gage. The smallest size of dinkey commonly used weighs 8 short tons, and is listed as having a tractive pull of 2,900 lbs. on a level track. Whether the actual tractive capacity is exactly 2,900 I do not know; but it must be approximately that, for any locomotive can exert a pull of 25% of the weight on its driving wheels even on clean rails.

The loads that a dinkey can pull, however, are much over-estimated in catalogues, due to too low rolling resistances assumed for cars. It is said in some of the catalogues that the resistance to traction is $6\frac{1}{2}$ lbs. per short ton. This rate applies only to the best of standard gage railway tracks with heavy rails, well ballasted, and with heavy wheel loads. On a contractor's narrow gage, light rail track, the resistance to traction is probably not much less than 20 to 40 lbs. per ton, and at the point where the cars are loaded it is doubtless more, due to the dirt on the rails. It requires almost twice as great a pull to start a car as to keep it in motion.

The resistance due to gravity is 20 lbs. per short ton per 1% of grade; but, of course, the tractive power of a locomotive falls off 20 lbs. for every ton of its own weight for each 1% of grade.

Based upon these data, and upon the assumption that the resistance to traction is 40 lbs. per short ton, an 8-ton dinkey is capable of hauling the following loads, including the weight of the cars:

	Total tons.
Level track	70
1% grade	46
2% grade	33
3% grade	26
4% grade	21
5% grade	17
6% grade	14
8% grade	10

Note.—On a poor track not even as great loads as the above can be hauled.

Due to the accidents that frequently occur from the breaking in two of trains on steep grades, and from the running away of engines, it is advisable to avoid using grades of more than 6%.

When heavily loaded, a dinkey travels 5 miles per hr. on a straight track; but when lightly loaded, or on a down grade, it may run 9 miles an hour.

The following are the average struck measure capacities of the dump cars made by one firm (variations of weight of several hundred pounds occur, according to the make):

Capacity, cu. yds.....	1	1½	2	2½	3
Weight, lbs.	1,700	2,000	2,300	2,800	3,500

A car seldom averages its struck capacity of earth measured "in place," even when the car is heaped full with a shovel; for not only are there vacant places in the corners of the car, but the loose earth is 20% to 30% more bulky than earth "in place."

The number of dinkeys required to keep a shovel busy can be estimated from the data given. On short hauls (1,000 ft. or less) one very often sees only one dinkey serving a $1\frac{1}{2}$ -yd. shovel. In such cases the dinkey is not heavily loaded, so that it can run fast, and by having enough men to dump a train of 6 cars in 2 or 3 mins. a fairly good daily output of the shovel can be secured.

In dumping the cars, estimate on the basis of one 3-yd. car dumped by each man in $1\frac{1}{2}$ to 2 mins. The men work in groups of 2 or 3 in dumping the cars, and enough men are usually provided on the dump to dump a train in 3 mins.

When two or more dinkeys are serving one shovel, and long

trains (12 cars) are being used, it would seem that very little lost shovel time would occur due to switching in an empty train; but, even under favorable conditions, I find that $1\frac{1}{2}$ to 2 min. per train are lost in switching. This is another reason why a shovel served by only one dinky makes so good a showing on short-haul work. Still another reason is that at the time the shovel is shifting forward, the dinky can often make its round trip; and on shallow face work this shifting of the shovel occurs frequently.

The method of using a hoisting engine and cable to move the cars is quite common in railroad work, where the hauls are short, say 1,000 ft. or less. The track is laid on a rather steep grade, at least 3% from the pit to the dump, and the cars coast down by gravity usually in trains of 4 cars holding about 2 cu. yds. each. The hoisting engines pull the cars back with a wire rope. A team of horses will have all it can do to pull a train of 4 such cars even on a slight down grade to the dump. As a matter of fact, a team that is working steadily cannot be counted on to pull more than two cars holding 2 cu. yds. each, on a level track of the kind ordinarily used in contract work.

The 3-ft. gage track commonly used is laid with rails weighing 16 to 40 lbs. per yard of single rail. A 30 or 35-lb. rail makes a track that is not easily kinked under the loads, even when ties are spaced 4 ft. centers. A 6 × 6-in. tie, 5 ft. long, is the best size. I have tried 4 × 4-in. ties, but they are easily split by the spikes, and are not of much value after being used once; whereas the 6 × 6-in. ties can be laid 4 to 6 times. After the rails and ties are delivered, and the roadway graded, such a track can be laid for \$100 per mile, or \$2 per 100 ft., when wages are 15 cts. per hr. And the track can be torn up and loaded on wagons for \$1 per 100 ft.; there being 1 ton of 30-lb. rails and 375 ft. B. M. of 6 × 6-in × 5-ft. ties per 100 ft. of track.

In railroad work it is usually necessary to build a trestle through which the cars are dumped in making the embankment. The trestles usually consist of two posts per bent, the posts being of round timber, capped with a squared stick, and sway braced with round timber saplings. In the section on Timberwork the reader will find data on the cost of trestlework.

Summary of the Cost of Steam Shovel Work.—As above stated, shovels are so designed that about 8 dipperfuls can be averaged per minute when actually loading cars; but I find that even with well arranged tracks, and a good high face, the necessary delays of shifting the shovel ahead, switching the trains, moving the shovel back to start a new swath, etc., keep the shovel idle about half the time. Occasionally, under exceptionally favorable conditions, a shovel may average 8 or $8\frac{1}{2}$ hrs. of actual shoveling per 10-hr. day.

The size of the dippers, as listed in catalogues, often refers to dippers heaped full of loose earth. I find that the actual "place measure" averages about 80% less than the listed capacity of a dipper, for not every dipper goes out full, and even if it does the earth is not as compact in the dipper as in place.

On the basis of 3 dippers loaded per minute of actual work, we have the following for dippers of different sizes:

—Dipper.—		—Output in Cu. Yds.—	
Nominal.	Actual (average).	Steady Shoveling.	
Yds.	Yds.	10 hrs.	5 hrs.
1	0.7	1,260	630
1½	1.0	1,800	900
2	1.4	2,520	1,260
2½	1.7	3,060	1,530

We see that where the shovel is actually shoveling 5 hrs. out of the 10 (and this is a good average), a 1-yd. dipper will load 630 cu. yds.; a 1½-yd. dipper, 900 cu. yds.; a 2½-yd. dipper, 1,530 cu. yds. These are not merely theoretical outputs, for I have monthly output records that show these averages for each 10-hr. shift. However, the track arrangement must be such that cars are promptly supplied to the shovel, if any such average as 900 cu. yds. per day per 1½-yd. dipper is to be maintained.

Taking the 1½-yd. dipper as the common size, we may say that in "average earth," with cars promptly supplied, 900 cu. yds. are a fair 10-hr. day's work; but if only one dinky is used, the lost time may easily be increased to such an extent that 650 cu. yds. become a good day's work in "average earth." In hardpan, or exceedingly tough clay, the output of a shovel may fall to about half the output in "average earth"; that is, 450 cu. yds. per 10-hr. day with a 1½-yd. shovel.

The size of shovel to select for any given work depends upon the yardage of earth in each cut—not upon the total yardage in the contract. On very light cuts, such as street and road work, cellars, etc., a small shovel with a ½ to ¾-yd. dipper is usually most economic. Use a small 26-ton traction shovel, with 1-yd. dipper for small railway cuts, where moves from one cut to another will be frequent. Use a 55 to 65-ton shovel with 1½ to 2½-yd. dipper where cuts are heavy, and moves not very frequent. Use a 75 to 90-ton shovel, with 2½ to 3½-yd. dipper, on heavy cuts, where moves are infrequent. Of course a heavy shovel with a small dipper is necessary in hardpan and very tough material.

The cost of operating a 55-ton shovel is ordinarily as follows, assuming 22 days worked during the month, and 6 months worked during the year, or 132 days actually worked per year:

Shovel Crew:	Per Day Worked.
1 engineman on shovel, at \$125 per mo.....	\$ 5.70
1 craneman on shovel, at \$90 per mo.....	4.10
1 fireman on shovel, at \$65 per mo.....	3.00
6 pitmen, at \$1.75 per 10-hr. day.....	10.50
1 night watchman, at \$50 per mo.....	2.20
Total shovel crew	\$ 25.50
Coal for shovel, 1½ tons, at \$4, delivered.....	5.00
Water	2.00
Oil and waste.....	0.50
Interest on \$7,200 shovel at 6% per year + 132 days.....	3.25
Repairs on \$7,200, 3% per mo. + 22 days.....	10.00
Depreciation on \$7,200, 6% per year + 132 days.....	2.25
Total steam shovel crew, fuel, repairs, etc.....	\$ 50.50

Moving and housing shovel once during year, say, \$500 ÷ 132 days	4.00
Total charges on shovel.....	\$ 54.60
Train Crew:	
2 enginemen (on 2 dinkeys), at \$3.....	\$ 6.00
2 trainmen, at \$2.....	4.00
4 dumpmen, at \$1.75.....	10.50
Total train crew.....	\$ 20.50
Coal for 2 dinkeys, 0.6 ton, at \$4.....	\$ 2.40
Water	1.50
Oil and waste.....	0.50
Interest on \$8,000 (2 dinkeys and 24 cars), at 6% per year ÷ 132 days	3.65
Repairs on \$8,000, at 1½% per mo. ÷ 22 days.....	5.45
Depreciation on \$8,000, at 8% per year ÷ 132 days.....	4.85
Total train crew, fuel, repairs, etc.....	\$ 38.85
Moving and housing locomotives and cars once during year, same as for shovel.....	4.00
Total charges of locomotives and cars.....	\$ 42.85
Track Crew and Track:	
4 men grading and track shifting, at \$1.75.....	\$ 10.50
Interest on \$2,250 (rails (35 lbs. per yd.) and fastenings for 1 mile of track), at 6% ÷ 132 days.....	1.00
Depreciation on \$2,250, at 12% ÷ 132 days.....	2.00
Interest on \$750 (ties, at 30 cts. each, 2 miles track), at 6% ÷ 132 days.....	0.85
Depreciation on \$750 (ties), at 10% per mo. ÷ 22 days....	3.50
Total track crew and track.....	\$ 17.85
Supervision, Etc.:	
½ superintendent, at \$150 per mo.....	\$ 3.50
1 foreman, at \$75 per mo.....	3.50
1 timekeeper, at \$65 per mo.....	3.00
General management, office expenses, etc., 6% of daily payroll	4.00
Total supervision, etc.....	\$ 14.00
Grand total	\$128.80

Summarizing we have the following daily cost and cost per cu. yd. when the daily output is 1,000 cu. yds. (or 22,000 cu. yds. per month):

	Per day.	Per cu. yd. cts.
Shovel expenses	\$ 54.60	5.46
Train expenses	42.85	4.29
Track expenses	17.85	1.73
Supervision, etc.	14.00	1.40
Total	\$128.80	12.88

Tough material and unfavorable conditions frequently reduce the daily output to 600 cu. yds. and run the cost up to 21 cts. per cu. yd.

The most variable of the four main items of daily expense is Track Expense. Often a large crew of men is kept busy grading for new tracks, although it is rare that more than 10 or 12 men are thus engaged for each shovel crew.

The estimated percentages for repairs and depreciation are lib-

eral, but it must be remembered that repairs increase as the machines grow older, and that a high allowance should be made for depreciation to cover obsolescence, i. e., the "getting out of date" or behind the times.

Depreciation of ties is especially rapid in contract work, due to the destruction that occurs from frequent track shifting. Depreciation of rails is also rapid, due to their becoming kinked.

The foregoing itemization of cost should be taken merely to represent a fairly typical example, but each particular case will have its varying conditions that must be considered.

Where temporary trestles must be built to carry the cars out over proposed fills, as is common on railway work, the cost of the trestles must be added to the above figures. The cost of trestle-work can be estimated from data given in the section on Piling and Timberwork, bearing in mind, however, that much lighter timbers can be used for dinky locomotives and trains than for standard railway tracks. It should also be remembered that round poles can usually be secured for the legs or posts of trestle bents, and that each bent usually has only two legs. The squared stringers, ties and caps can usually be recovered, but the posts, sills and sway braces are buried permanently in the fill.

Cost of Digging a Well or Cesspool.—Circular wells or holes are often dug for water supply and for cesspools around buildings.

A well was dug on Long Island in a clay material with an occasional boulder. The material was stiff enough to stand up without shoring. The hole was 8 ft. in diameter and 24 ft. deep. For two days two men did the work, but, when a bucket had to be used, another man was added to the force. A three-legged derrick, with a crank on it, was used to hoist the bucket of earth. The excavation was made entirely with picks and shovels. There were 1,305 cu. ft. of material excavated, or about 48 cu. yds. A 10-hr. day was worked. The cost of the work was as follows:

2 men 2 days, at \$1.50.....	\$ 6.00
3 men 5 days, at \$1.50.....	22.50
Total	\$28.50

This gives a cost of 60 cts. per cu. yd. for excavating and hoisting the material and dumping it on the ground by the side of the hole. This cost is quite reasonable for this work.

Cost of Trenching, Cross-References.—Data on this subject will be found in the following sections of this book: Waterworks, Sewers, and Miscellaneous Costs. Consult the index under Trenches.

The Cost of Backfilling a Trench With a Scraper.†—Fig. 1 shows a Doan Ditching Scraper for back filling trenches or ditches.

To backfill a trench, a rope or chain about 20 ft. long is fastened to the cable chain on the scraper, and a team is hitched on to the end of the rope. The team, of course, works on one side of the trench. The scraper weighs only 75 lbs., and can be dragged back

**Engineering-Contracting*, Oct. 28, 1908.

†*Engineering-Contracting*, January, 1906, p. 11.

by one man, although some contractors prefer to have two men on the scraper, especially when the men are small.

In 10 hrs. a team and driver and one man on the scraper backfilled 400 lin. ft. of trench 2 ft. wide by 7 ft. deep. This is more than 200 cu. yds. backfilled at a cost of $2\frac{1}{2}$ cts. per cu. yd. With two men on the scraper, and working very hard, as much as 700 lin. ft. were backfilled in a day, which is equivalent to less than 2 cts. per cu. yd. In this case no tamping was required, but, even where tamping is called for, a scraper is much cheaper than a shovel for backfilling.

While good work can be done with the ordinary drag scraper, it is not so good a tool for backfilling as that described above, for three reasons: First, because a Doan scraper is lighter; second, because a drag scraper is narrower; and third, because a drag

Fig. 1. Doan Scraper.

scraper is not so quickly dumped. The Doan scraper is made of oak, shod with steel on the cutting edge. This cutting edge is 4 ft. long, which means a good wide swath cut at each forward pull. In addition to its use for backfilling, the scraper is also suited for use in digging ditches, leveling embankments, etc. The scraper is made by the Sidney Steel Scraper Co., of Sidney, Ohio.

Prices for Drainage Ditch Work.*—The following figures on ditch construction in Minnesota were given by Mr. George A. Ralph, State Drainage Engineer, in a paper before the Minnesota Sur-

**Engineering-Contracting*, July 10, 1907.

vopers' and Engineers' Society. The figures are the average prices and are based on contract prices for work on which Mr. Ralph was engineer; they cover a period extending from 1886 to 1906:

Blip scraper work:	Per cu. yd.
Not exceeding 6 ft. in depth.....	\$0.10
Not exceeding 10 ft. in depth.....	0.12
Not exceeding 12 ft. in depth.....	0.14
Elevating grader work.....	0.08
Shovel work, 3 to 6 ft. deep.....	0.18
Shovel work, 8 to 10 ft. deep.....	0.20
Hayknife work, 3 to 4 ft. deep.....	0.12
Hand labor in timbered swamps.....	0.15 to 0.20
Good dredge work.....	0.08
Dredge work, unfavorable conditions.....	0.10 to 0.16
Capstan ditch, plow work.....	0.40 to 0.60

Cost of Boring Test Holes in Earth.*—For the purpose of prospecting, testing foundation sites, well drilling, etc., it is often necessary to bore through sand, gravel, clay, etc. There are four common methods of boring in earth: (1) By means of an earth auger; (2) by a churn drill; (3) by driving a pipe and washing out the earth inside the pipe with the aid of a force pump, called "wash boring"; and (4) by post hole diggers of various forms.

Any of these methods (except the third) may be used either with or without a casing pipe to preserve the sides of the hole from crumbling in, and any kind of power may be used. In soil that crumbles readily a casing pipe is always necessary where the hole must be sunk to any considerable depth; but by the exercise of a little ingenuity it is often possible to bore even in dry sand without using a casing pipe. We are indebted to Mr. J. M. Rudiger for the following hint, which will be found exceedingly useful in boring in sand up to depths of about 20 feet: Pour one or more barrels of water on the sand at the site of the proposed bore hole. The water will pass vertically downward, spreading no great distance laterally. In the sand thus made damp, an earth auger may be used to bore without any caving in of the sides. If the hole is to be used as a well, lower a casing pipe into it after water has been struck.

Cost of Hand Auger Prospecting.—Mr. Charles Catlett is authority for the following methods of prospecting for deposits of hematite in Virginia. The set of tools consists of a steel auger bit twisted into a spiral (4 turns) 3 in. diam., the steel of the bit being $\frac{1}{4}$ in. thick and 12 in. long and provided with a split point. This bit is welded to an 18-in. length of 1-in. wrought pipe having a screw threaded end. Another chopping bit for use in hard material is made of $1\frac{1}{2}$ -in. octagon steel with a 2-in. cutting edge, and is welded to a length of 1-in. wrought pipe. As many lengths of 1-in. wrought pipe are provided as necessary, with screw couplings. An iron handle, 2 ft. long, is provided with a central eye and with a set screw so that it can be fastened to the 1-in. pipe at any place. A 10-ft. length of $1\frac{1}{4}$ -in. pipe, threaded at each end for connection to the 1-in. pipe, is provided for use in giving weight to the pipe drill rods in churning. The other tools are: A sand pump of 1 or 2 ft. of 1-in. pipe with a leather valve, and cord for lowering it;

**Engineering-Contracting*, January, 1906, p. 11.

two pairs of pipe tongs; two monkey wrenches; 25-ft. tape; flat file; spring balance; oil can; water bucket, etc. In boring through soft material, the auger is rotated by two men, raised every few minutes, scraped clean, and the handle fastened higher up on the rods. In hardpan or rock the churn bit is used, and the sludge is removed either with the auger or with the sand pump. The greatest depth penetrated with this outfit was 80 ft. Up to a depth of 25 ft. two men suffice; from 25 to 35 ft., three men; 35 to 50 ft., three men, the third man standing on a rough timber frame 15 or 20 ft. high, so that the pipe need not be unjointed when raised. For depths of 50 ft. more the pipe is unjointed when raised. The following are progress records on eight holes:

Cost of Wash Borings on a Canal Survey.†—Mr. A. W. Saunders is author of the following:

These data were obtained on a survey of 95 miles, covering the operations of a year. The line ran over a little rough country, two rivers and a lake. The land was not "rocky," though there were some stony plots of course.

The equipment was complete in all its details, thus enabling an economic and thorough prosecution of the work, i. e., making test borings to locate the "rock line" or elevation of the rock in the earth, on a survey of a ship canal.

Two parallel lines were run 500 to 1,500 ft. to the right and left of the main line. This necessitated a systematic and constant hustle to prevent a stalling of the work, for one machine often was on one side of a river and others scattered over a mile of ground.

Fig. 2 is the Carpenter wash drill. The pump is to the left and rear of the hammer. This machine, equipped for 120 ft. of work with pump, 500 ft. of 1½-in. water pipe and all necessary accessories, will now cost \$200. This machine is readily transported by hand through swamps, marshes or even rivers; and, with its tool box, makes but a small one-horse load. The illustration shows a machine rigged to put down deep holes (100 ft.). Fig. 3 shows method of pulling the pipe.

Two 2-oz. sample bottles are shown (just below the foreman's knee). The notes are recorded in his note book suitably ruled; samples of the borings are obtained, the bottles labeled and all sent into the office where the whole is plotted; the notes and samples are filed.

†*Engineering-Contracting*, Dec. 3, 1908.

Fig. 2. Wash Drill.

Fig. 3. Pulling Pipe.

Fig. 4 is the Sullivan earth drill. Water is forced through the drill rods down to the foot or "shoe" of the casing and then up in the casing bringing with it the material drilled through, a sample of which is thus obtained and its "condition" noted. This

Fig. 4. Earth Drill

machine is not as easily moved as the other and trails along behind a wagon. It will cost \$300 completely equipped for 100 ft. of work with 500 ft. of 1½-in. water pipe, pump, etc. A portable blacksmith or repair shop, 12 x 12 x 8 ft., equipped with pipe working tools, forge, etc., is figured in with the cost given below.

The total amount of work in one year's continuous work of 4 crews (increased to 8 crews for 5 months), was 750 holes aggregating 33,711 ft. exclusive of water. The cost of the entire outfit (8 machines complete, repair shop and tools) was considered sunk in the enterprise. The total cost was \$21,862.12, or \$230 per mile of survey, or 64.9 cts. per ft. of boring, divided as follows:

Salaries and subsistence	\$18,593.46
Traveling expenses	189.48
Plant, tools, repairs	2,242.41
Explosives	508.82
Freight and express charges	129.17
Office expenses	199.28
	<hr/>
	\$21,862.12

This includes its share of the expense of the chief engineer, assistant engineer and other engineering work, as well as the plotting, etc. The actual cost of all borings, exclusive of the cost of the plant, repairs, superintending, freight, express, traveling and incidentals, was 48.7 cts. per ft. of boring, much of it through hard compact material.

The scale of wages was: Assistant engineer, \$150 per month; superintendent, \$100; assistant superintendent, \$60; foreman, \$45; laborers, \$20; all a monthly rate, with subsistence furnished. A teamster with a team received \$90 per month and "found" himself and team. A regular crew consisted of a working foreman and 4 men.

I used a Carpenter machine on the Wachusett Aqueduct, Massachusetts, and often obtained a sample of earth at a depth of 240 ft. in one-half day.

On another job in New York state, a Carpenter, with some of my Massachusetts men, was 17 days on one hole, including lost time by reason of bad weather, breakages and 2 Sundays; 55 half-pound sticks of dynamite were used blasting and blowing boulders out of the way. This was an unusual condition, yet I quote it, as I had to meet it and overcome it. It figures in with the cost.

On water the machines are set up on rafts 17.5 x 24.5 ft. composed of timbers, planks and oil barrels and constructed so as to allow the raft to be moved away from the pipe should occasion require.

There need be but little time lost during the winter. Greater care is necessary, however, to prevent the pumps and pipes from freezing at night.

Comparing the working of the two types of machines, during one-quarter of the year (3 months), the Carpenter machine drove 21 holes to a total depth of 1,501.6 ft. at a total labor cost of \$760.35, explosives and freight \$22.69, which is equivalent to 52.1 ct. per ft.

The Sullivan machine drove 22 holes in the same time to a total depth of 1,384.6 ft. at a labor cost of \$687.04, explosives and freight \$32.48, which is equivalent to 51.9 ct. per ft.

Comparing these two same machines on a single hole each, we have:

	Carpenter.	Sullivan.
Loose material	0.0 to 43.6	0.0 to 53.3
Hard packed	42.6 to 72.0	52.3 to 74.5
Rock	72.0 to 73.8	74.5 to 75.8
Time boring (including 1 rainy day)....	1.85 days	4.25 days
Cost per foot	43.7 cts	45.8 cts
Dynamite (40%)	3.5 lbs.	5 lbs.
Electric exploders	7	5
Time removing drill rod.....	9 mins.	13 mins.
Time removing casing	30 mins.	30 mins.

Other comparisons might show advantage to the other machine.

As our business was to locate the rock, I caused the men to drill into and blast upon it, thus making sure of it. The rock drills come along later, but are not subjects of this article.

Neither of these machines is adapted to drilling in rock. They can drive the casing to the rock and no further.

Cost of Wash Drill Borings on a Canal Survey.*—In surveying in 1897-1900 the several possible routes for the proposed ship canal or deep waterway connecting the Great Lakes with Atlantic tide waters the character of the excavation was sought by making 25 diamond drill borings and some hundreds of wash drill borings along the various routes. In the following paragraphs we summarize from the scattered data in the report of the Board of Engineers such facts as are given regarding the methods and costs of making the wash borings. These figures are not so complete in detail as might be wished, but, with the omissions kept in mind, should prove a reasonably good guide for engineers about to undertake similar work. In presenting the records we shall take up the several routes separately. First, however, some of the features common to the work as a whole will be mentioned.

Organization.—The organization of the boring parties on the several routes varied somewhat. Usually, however, they comprised for each route a superintendent having charge of all the boring gangs and one or more boring gangs composed of a foreman, three or four laborers, and a teamster with team and wagon. The wages paid are not given in the report, but for similarly organized gangs for diamond drill work they were as follows: Superintendent, \$125 per month; foreman, \$100 per month; laborers, \$55 per month; teamster with team and wagon, \$75 to \$90 per month. It is fair to assume, since the time and location of the borings were the same and the work was done for the same employer, that about the same wages were paid to the wash boring gangs.

Method of Borings.—The boring process was the usual one of the method, but the outfits used varied considerably. Whatever the outfit the process consisted in alternately "driving casing" and "drilling" until "bottom" was reached. Where obstructions were encountered that could not be passed by drilling, they were removed by pulling the drill rod and lifting the casing 3 or 4 ft. and then firing a stick or two of dynamite at the bottom of the hole.

Routes.—In making the surveys, two routes were considered for getting from Lake Erie to Lake Ontario. One was from Tonawanda via Lockport to Olcott and the other was from Lacalle below Tonawanda to Lewiston, both on the Niagara River. Two routes were also considered for getting from Lake Ontario to the Hudson River. One route was from Oswego via the Oswego River, Oneida Lake and the Mohawk Valley to Norman's Kill on the Hudson, and the other was along the St. Lawrence River to Lake St. Francis, then up Lake Champlain and across country to the Hudson River.

Tonawanda-Olcott and Lacalle-Lewiston Routes.—The borings for these routes were taken on sections 1,500 ft. apart and were carried to rock or to a depth below the bottom of the proposed 30-ft. channel. On the Tonawanda-Olcott route the materials penetrated were sand and gravel and sand, clay and sand, hard clay and hardpan,

**Engineering-Contracting*, March 27, 1907.

and on the Lasalle-Lewiston route they were sand, gravel, clay and hardpan. The force making the borings consisted of one superintendent and three boring parties, each composed of a foreman, three laborers and a teamster with a team to haul water and move the machines from hole to hole. In all 404 holes were bored to an aggregate depth of 9,624 ft. The cost of the work was as follows:

Item.	Total.	Per foot.
Salaries	\$5,552.11	\$0.5769
Traveling expenses	123.92	0.0128
Plant	649.05	0.0673
Explosives	223.87	0.0232
Freight and express	0.70
Office expenses	33.00	0.0034
	<hr/> \$6,582.65	<hr/> \$0.6863

These figures do not include the cost of surveys locating the bore holes, but they do include the total cost of the plants which was considered sunk when the work was completed.

Oswego-Mohawk Route, Western Division.—The borings on the Western Division of the Oswego-Mohawk route extended from Oswego to Rome and comprised the work in Peter Scott's swamp, Oneida Lake and Oswego River and Oswego Harbor. For the Oswego river and harbor work the machines were mounted on small flatboats with open wells at the center. The work on Oneida Lake was done through the ice. In all 750 holes were bored to an aggregate depth of 33,711 ft. and including the depth in water. The cost of the work was as follows:

Item.	Total.	Per foot.
Salaries	\$19,645.96	\$0.5827
Traveling expenses	319.75	0.0065
Plant	3,035.00	0.0900
Explosives	508.32	0.0091
Freight and express	203.77	0.0065
Office expenses	199.28	0.0059
Total	<hr/> \$23,812.08	<hr/> \$0.7007

Oswego-Mohawk Route, Eastern Division.—The work on this route comprised 290 soundings by hand with a steel rod and 1,562 actual borings, amounting together to 55,521 ft. aggregate depth. As indicating the character of the boring the following table is given:

Earth	7,611
Sand	20,706
Clay	9,880
Blue clay	177
Gravel	2,815
Shale	161
Hardpan	100
Quicksand	1,529
Sand and gravel	2,728
Sand and clay	3,176
Clay and gravel	760
Sand and shale	263
Clay and shale	902
Gravel and stone	105
Gravel and boulder	177
Hardpan and boulder	87
Hardpan and stone	34
Sand and cobble	63

Gravel and shale	292
Sand, gravel and stone	77
Sand, loam and mud	900
Sand, clay and gravel	1,843
Gravel and cobble	31
Mud	417
Rock	626

Total penetration, ft.....55,521

Four types of machines were used on the work, two being manufacturers machines, one a Pierce well boring machine and one a Sullivan wash drill, and two being home-made affairs. The first of these latter consisted of a simple tripod, with a pulley at the apex and a rope passing over the pulley and attached alternately to a wooden maul for driving casing and to the drill rod. The second of these home-made devices was more elaborate. It consisted of a frame like a small pile driver, that is, two leads with back braces mounted on base timbers. The leads were 15 ft. high and the distance between the bottoms of the leads and back braces was 4 ft. The base extended 2 ft. in front of the leads. A pulley between the leads at the top and one set in brackets in front of it provided for handling the hammer and the drill rods. The hammer was of iron, with a hollow in the bottom for a wooden cushion. In operation the machine was guyed by two wire ropes. It could be loaded onto a two-horse wagon in 15 minutes and unloaded and set up in the same length of time.

The boring gangs each consisted of a foreman, three or four laborers and a teamster and double team. A superintendent of borings had charge of all the gangs. The borings varied from a few feet to 190 ft. in depth. The cost of the work was as follows:

Item.	Total.	Per ft.
Salaries	\$28,470.80	\$0.4769
Traveling expenses	687.62	0.0124
Plant, repairs and tools.....	2,387.03	0.0413
Explosives	182.20	0.0033
Freight and express.....	181.56	0.0032
Office expenses	298.08	0.0054
Total	\$30,057.29	\$0.5419

Champion Route, Ogdensburg to Lake St. Francis.—The borings along this route were made partly on land and partly in water, using a Sullivan machine. The division was as follows:

Item.	No. holes.	Ft. depth.
Sand borings	148	7,052
Water borings	151	2,123
Total	299	9,175

The cost of the work was as follows:

Item.	Total.	Per ft.
Salaries	\$6,103.12	\$0.6552
Traveling expenses	438.37	0.0477
Plant, repairs, tools.....	830.92	0.0905
Explosives	319.38	0.0347
Freight and express.....	72.54	0.0078
Office expenses	54.64	0.0059
Total	\$7,818.87	\$0.8412

Champlain Route, Hudson River Division.—This line of borings began in Lake Champlain at Port Henry and ran to Whitehall, thence across country to Fort Edward on the Hudson River and thence down the river to the State Dam at Troy. From Troy to Fort Edward one party consisting of a foreman, three laborers and a teamster and 2 horses made the borings on land, and one party consisting of a foreman and three laborers made the borings in the river. At Fort Edward the river party was transferred to land, giving two land parties to Whitehall. For the river work a catamaran was used since it could be taken apart and carried around dams. On Lake Champlain the borings were made through the ice. As most of the work was done in cold weather it was necessary to house the machine to keep the pumps and water swivel from freezing. A small shanty was built on runners and hauled from hole to hole. It had trap doors in the floor and roof and contained a stove. With this arrangement boring was carried on successfully at -30° F. The materials penetrated on Lake Champlain were silt and sand and boring was very easy as is indicated by the fact that 20,169 lin. ft. of borings were made for \$2,368, or 11.24 cts. per lin. ft. The itemized cost of the borings as a whole was as follows:

Item.	Total.	Per ft.
Salaries	\$6,288.23	\$0.1083
Traveling expenses	156.49	0.0027
Plant, repairs, tools.....	561.27	0.0097
Explosives	40.74	0.0007
Freight and express.....	50.40	0.0008
Office expenses	74.12	0.0013
Total	\$7,171.25	\$0.1235

The total aggregate depth of hole was 57,991 lin. ft.

Hudson River Survey, Hudson to Troy, N. Y.—The borings along this line were made with an outfit mounted on a catamaran and on scows; silt, clay, coarse and fine sand, gravel and boulders were the materials penetrated. A $2\frac{1}{2}$ -in. casing and "B drill rods," with X-bits were used. The drilling gang consisted of one foreman and three laborers. For removing obstructions 40% Atlas powder was used, from one-half stick to two sticks for a charge. To get some of the holes below the depth required for a 30-ft. channel or to rock required from 10 to 20 shots. In all 1,386 borings were made to an aggregate depth of 28,965 ft. The cost of the work was as follows:

Item.	Total.	Per ft.
Salaries	\$5,652.57	\$0.1951
Traveling expenses	299.89	0.0104
Plant, repairs, tools.....	1,105.63	0.0381
Explosives	105.98	0.0037
Freight and express.....	68.63	0.0023
Office expenses	29.71	0.0011
Total	\$7,272.40	\$0.2507

Cost of Boring Test Holes.*—In making test borings most machines use water to wash up the material or to make the drilling easier, hence these borings are called "wash borings." The water changes some earths materially, softening some and washing away fine sands. For this reason wash borings are not always satisfactory, where samples of the earth are desired. A machine that will do this work without water, and, at the same time, takes a core, is of great value to engineers and contractors.

Fig. 5 shows a light, inexpensive and portable machine that will do this work quite cheaply. Its operation is simple, and the general principle is as follows:

The drilling is done with one of several tools—adapted to the particular kind of material being drilled—attached to the drilling rod. The tool and rod are operated inside the casing by the men on the platform, who raise and drop them like a "churn" drill. The men on the ground rotate the casing, which has a sharp cutting shoe on the lower end. The casing, with its burden of platform and men, thus keeps cutting and sinking into the ground several inches ahead of the tool. A horse may be substituted for the men who rotate the casing.

The material which enters the casing is drilled and forced into a sand pump at the same time. The pump is occasionally lifted out of the casing, emptied and the contents noted. Any material can be penetrated until the solid bed rock is reached. An accurate core is obtained, and the exact nature of the ground drilled is readily shown.

Four-inch pipe is generally used, with a special coupling that makes a perfectly flush joint; that is, all of the couplings have the same outside diameter as the pipe, which makes it very easy either to sink or remove this casing. Instead of the 4-in. pipe or casing, 3-in. or even 2½-in. casing can be used if desired, and it will make more rapid work, but of course would give a smaller core.

After the hole is finished, the pipe is easily withdrawn because the casing, having been constantly rotated, is always loose, both while sinking and removing.

In estimating the cost of operating this drill there is little else to be calculated besides the labor, as the repairs constitute a small part of the operating expense. Of the laborers employed, one must be a foreman or driller, another an ordinary pipeman, and the balance of the crew common laborers. When the casing or piping with its platform is rotated by a horse, instead of the men on the ground, it effects quite a saving in the cost by dispensing with three or four men. If the ground does not contain heavy boulders, and the holes are not over 25 or 40 ft. deep, six men will be sufficient, or three or four men and a horse; the cost of this crew will generally be not more than \$15 00 per day.

With the 4-in. size hole 50 ft. of hole per day have been drilled at a cost of 30 cts. per foot. Twenty-five to thirty feet of hole per

**Engineering-Contracting*, Jan. 29, 1908.

day will be averaged through hard cemented gravel containing boulders.

Mr. Thos. G. Ryan used one of these drills on Long Island putting down a number of holes through sand and gravel, with occasional strata of clay, and in some cases encountering large boulders. About 40 test borings were made, each hole averaging 59½ ft., the total lineal feet drilled being 2,454. The time consumed in this work was 73 days, working 9 hrs. per day. The cost given below includes the drilling, drawing the casing, and moving and setting up drill, thus covering a number of removals over a considerable period of time.

The total cost of the work was:

1 foreman 73 days, at \$4.00.....	\$292.00
1 pipeman 73 days, at \$3.00.....	219.00
3 laborers 73 days, at \$1.50 each.....	328.50
1 horse 73 days, at \$1.00.....	73.00
Depreciation, interest, renewals and incidentals..	81.74

Total cost\$994.24

The average work done each day was 33.6 ft., which gives the following unit cost:

	Per lin. ft.
Foreman	\$0.119
Pipeman	0.089
Laborer	0.134
Horse	0.030
Interest, repairs, deprec., etc.....	0.033
Total	\$0.405

The machine is the Empire Hand Drill, made by the New York Engineering Co., 2 Rector St., New York City.

In this article* we give the work of a hand drill used for prospecting in Colombia, South America. The drill was an Empire Hand Drill, manufactured by the New York Engineering Co. of New York. The work was done under the direction of Mr. Clarence R. Snow, during the autumn of 1903.

The work was done with native peons or Indians, who had never seen machinery of any kind before. The country in which the holes were being sunk was covered with forest, the bush and undergrowth in many places being very heavy. To move the drill from hole to hole a narrow path was cut through the undergrowth 6 or 7 ft. high. A small flat bottom boat was used to carry the drill across the river, there being consumed about half an hour to do this. As there are no roads in Colombia it would be almost impossible to work a steam drill, owing to the difficulty of moving it from place to place.

Four men were used to turn the casing, and four men did the drilling, an additional man being used for cutting trails. The entire crew was used to draw the casing and move the drill from hole to hole. The following is a record of seven days' work.

First Day.—Carried outfit across river in boat and began hole No. 1. Made 14 ft. in top soil and 11 ft. in gravel by 5 p. m.

*Engineering-Contracting, Jan. 6, 1909.

Second Day.—Finished hole No. 1, $2\frac{1}{2}$ ft. more to bed rock, total $21\frac{1}{2}$ ft. Pulled casing and began hole No. 2, 100 ft. distant before noon, and sunk the hole 17 ft. deep to bed rock before 4 p. m. Pulled casing and moved to hole No. 3, drilling 9 ft. in overburden.

Third Day.—Finished hole No. 3, 24 ft. deep. Pulled casing and started hole No. 3 by 2 p. m. Passed through 12 ft. of overburden and 10 ft. of sand and gravel by 5 p. m.

Fourth Day.—Finished hole No. 4, which was 28 ft. deep to bed rock. Pulled casing, cut trail and moved to hole No. 5, 300 ft. northeast of hole No. 4, and started new hole by noon. After drilling 17 ft. through overburden an old buried tree was struck, but the drill went through it easily. By 5 p. m. 22 ft. were made in this hole.

Fifth Day.—Finished hole No. 5, 28 ft., and after pulling casing began hole No. 6. Got down 14 ft. in overburden and 9 ft. in gravel by 5 p. m.

Sixth Day.—Finished hole No. 6, going down 9 ft. more to bed rock. Moved outfit across the river and about a mile up the river, and at 2:45 started hole No. 7. Made 6 ft. in overburden and 9 ft. in gravel by 5 p. m.

Seventh Day.—Finished hole No. 7, 29 ft., to bed rock, and moved 50 ft. north and sunk hole No. 8, 22 ft., to rock. Started hole No. 9, 50 ft. north, and made 4 ft. in top soil by 5 p. m.

Thus in seven days of drilling $213\frac{1}{2}$ ft. were drilled, an average of $30\frac{1}{2}$ ft. per day. It will be noticed that as the men became accustomed to the work, they improved a little each day.

With the Empire drill an auger drill spoon is used that will cut through hard soils, roots and sunken logs and easily penetrates gravel. It picks up any material and brings it as a core to the surface with a minimum amount of disturbance of the material as it actually lies in the ground. Water, as a rule, is not used to assist in drilling, so the auger will pick up the finest particles of gold. If it is desired to use water in drilling it can be done. The casing is pulled by levers with a very simple device.

With wages at \$1 per day for the men the expenses were about \$16 per day, allowing \$1 for incidentals, the cost per foot was about 83 cts. With standard wages the cost per lin. ft. would have been about 47 cts.

Cost of Testing for Bridge Foundations.*—Mr. F. H. Bainbridge is author of the following:

This article is confined to bridge foundations, although much of what follows is also applicable to foundations for buildings and hydraulic structures and preliminary examination for tunnel construction.

Two methods of testing only are effective, an open pit or well for shallow foundations and the core drill for deep foundations. Sound-

**Engineering-Contracting*, Nov. 25, 1908, reprint from "Mine and Quarry."

ing with gas pipe or rods in shallow foundations and the common well drill in deep foundations are not satisfactory. Fig. 6 shows two cross-sections of a stream at the same point, the dotted line being the line of supposed ledge rock as determined by a well drill operating a chopping bit; and the full line, the correct location of the ledge rock, determined with a Sullivan "HN" diamond core drill.

In general two sets of borings should be made for an important bridge crossing; the first set, a number of borings on the center line of the proposed location, to determine whether the site is a favorable one, and, if favorable, to determine by approximate estimate the most economical location of the piers and the length of the spans. In a general way it may be assumed that the economical relation is reached when the cost of the substructure equals the cost of the superstructure; but inasmuch as the cost of the superstructure can be determined with considerable accuracy, while the cost of the substructure is involved in great uncertainty, the length of the spans selected should exceed that of the apparent economical relation. The length of spans chosen may also be influenced by other than economical considerations, such as government requirements, or the liability of ice to gorge against the bridge.

Having made a tentative location of the piers, borings should be made at each pier, and in the case of pneumatic or open dredged caisson foundations, one boring should be put down at each of the four corners of the caisson.

The preliminary borings may often be dispensed with when there are well records on both sides of the river in the vicinity. These well records can almost always be found in the various state geological reports, which can be had at any public library in the state. In case of the borings at Pierre, South Dakota, to be described later, the well records were so good that borings to determine the length of the spans were not necessary.

In cases where pile foundations are feasible and the river bottom is firm enough to lay concrete on, no borings are necessary, the required length of piling being best determined by driving experimental piles; but where the river bottom is soft, as it is in most streams with a sluggish or reversing current, borings should be made, the softer material being taken out dry with a sawtooth bit. This is feasible in the hardest clay or the softer shales and gives a perfect knowledge of the material encountered. Unless dry cores are taken when feasible, a hard clay in every way suitable for a foundation may be overlooked and provision made for carrying the foundation farther down than necessary.

In pneumatic work an accurate set of borings with a core drill is of incalculable value. These advantages are.

- 1st. The final location of the caisson can be accurately determined and cut stone and timber ordered without any waste or delay waiting for material for which no provision had been made.

- 2d. The contractor in bidding on the work knows exactly what material is to be encountered, and will make a lower bid when there

Fig. 6. Profile of Borings.

is no uncertainty. The difference in cost between handling in a caisson material which can be taken out through the blow pipe and material which must be locked out in buckets is very great.

3d. The piers can be located in the most economical position. Often a change of a few feet in locating a pier may make a difference in cost of tens of thousands of dollars.

4th. Much can be learned as to the character of the foundation that cannot be learned from the interior of the caisson. In limestone formations subterranean caverns are common, and in both lime and sandstone formations overhanging subterranean cliffs are found. The existence of these can be determined with the drill, but cannot be learned from the interior of the caisson.

Nearly the whole North American continent north of the Ohio River and east of the Missouri River has at various periods been covered with glacial drift; in fact, the Ohio and Missouri Rivers were formed by glacial action. Below the recent alluvial deposits in a riverbed in this district will be found glacial deposits of sand, gravel, clay, till, or boulders, sometimes all together in a heterogeneous mass. The extreme determined movement of the greatest glacial sheet was 1,500 miles. Boulders of granite from Canada and Minnesota were carried as far as Kansas and Missouri. One of the boulders in the river bed is therefore liable to be mistaken for ledge rock. Usually the character of the ledge rock can be learned from state surveys and samples secured from the outcrops, which are located in these surveys. When a core is obtained which can be identified as the same as ledge rock it may or may not be the actual ledge. If the core is granite or some older formation than the ledge rock, it is certain that a boulder has been reached. More recent rocks sometimes exist as pockets in earlier formations, so that a mere difference in the character of the rock from the bed rock is not conclusive evidence that bed rock has not been reached. When such a condition is liable to be found in any locality it will usually be mentioned in the state geological surveys. Boulders of granite and other hard rocks must be removed by placing sticks of dynamite at the bottom of the stand-pipe, withdrawing the pipe, and exploding with an electric battery. Boulders of softer rock can be cut up with the chopping bits and the casing driven through them. As boulders are usually separated by a matrix of sand or clay, the drop of the rods and the wash will show them as boulders and not bedrock in most cases, though this is not always conclusive, as pockets sometimes filled with sand are common in limestone ledges.

No definite rules can be given to cover all cases, and it is best, especially where there is any uncertainty, to put down a hole at each of the four corners of a pier. Where the drill strikes first rotten or sap rock, gradually increasing in hardness until known ledge rock is reached, this is conclusive evidence of bed rock. It is best to take out very soft, rotten rock with a saw tooth bit working dry.

Drill tests for foundations of the Chicago and Northwestern Rail-

way bridge across the Missouri River at Pierre, South Dakota, were begun in December, 1905. The drill used was a Sullivan Machinery Company's "HN" diamond drill, operating 2-in. core bits; 4½-in. stand-pipe and 3-in. casing, both with flush joints, were used. Borings at the sites of the river piers were made from the ice. In general four holes were put down at the site of each pier. On diagonally opposite corners holes were put down to about 90 ft. below low water, and on the other two corners to 60 ft. below low water. Thirty-three holes in all were put down, aggregating a length below the river bed or ground level of 2,379 ft., of which 1,456 ft. was in sand, gravel, and boulders, and 823 ft. in shale, with occasional small lenticular pieces of limestone. On the east or left bank heavy beds of glacial drifts were encountered and there was some difficulty in putting down stand-pipe and casing. The boulders were broken up with dynamite. In shale, saw tooth bits were used entirely, the berts bit being used only in the limestone pockets.

The work of setting up the drill was started December 5, 1905, and the first boring started December 8, 1905, with one shift working 10 hours. On January 17, 1906, a second shift working 10 hours was put on.

Shale was found practically level over the entire cross-section at 42 ft. below water. There was apprehension upon encountering an underground flow of water in the upper strata of the shale, but in no case was this more than a few feet below the top of the shale.

Caissons for the permanent piers penetrated the shale from 4 to 6 ft. and the material encountered was accurately described in the record of the borings. The cost of the drilling, including 10 per cent for depreciation of plant and tools, was about \$2,400, or about \$1 per ft.

In 1908 the Northwestern Railway began tests to locate suitable foundations for a new bridge over the Mississippi River at Clinton, Iowa. The same apparatus, tools, piping, etc., were used at Pierre, but the manner of working and the materials encountered were essentially different. These borings were started in April, and it became necessary to mount the drill on a scow. The scow was 15 ft. wide, 22 ft. long on the bottom and 27 ft. long on top, with a draft of 16 ins. when loaded. Experience in rough water showed that a scow 10 ft. longer on top with somewhat more rake to the ends would have been more serviceable. The tripod consisted of three pieces of Douglas fir, 5x8 ins. and 32 ft. long. An 8-in. wrought iron pipe near the center of the scow, bolted with a pipe flange to the bottom of the scow, made a well for passing the stand-pipe, 4½ ins. in diameter, and the casing, 2 ins. in diameter.

The materials encountered were in order as follows: Recent alluvial sands, glacial drift of gravel, sand and boulders, a shale consisting of sand with a clay matrix, and finally limestone bed rock. The upper stratum of bed rock was identified by fossils and general appearance as belonging to the Gower stage of the Niagara

series of Silurian rocks. This overlaid conformably rock of the Delaware stage of the same series. In the middle of the river the Gower rock and nearly 50 ft. of the Delaware rock had been entirely eroded. Great care was taken to ascertain the possible existence of subterranean pockets or overhanging cliffs in the rock. Only two of these pockets were found, however, both in the same boring, and these were only 1 and 6 in. in depth. Both were filled with sand, consisting of about equal parts of quartz and dolomite sand. Some of the borings were carried down 30 to 40 ft. into the bed rock to determine the possible existence of these subterranean pockets.

All the boulders encountered were such as could easily be broken with the chopping bit and no dynamite was found necessary. To determine the consistency of the shale, cores were taken out with saw tooth bits working dry, showing perfectly the consistency of the material. The saw tooth bit or the chopping bit working with the pump gave no idea of what this material was, and without the expediency of the dry core an excellent foundation would have been overlooked, and a foundation sought 30 ft. lower. It is intended to use pneumatic caissons in all the piers except the shore piers.

Borings in the limestone were made with a borts bit when the water was still, and with the chopping bit taking occasional cores with the saw tooth bits. Fully 95 per cent of the boring in the limestone was made with the borts bit. The work of mounting the drill was started April 2 and the first hole begun April 7. The work was finished June 6, working one shift of 10 hrs. per day.

The aggregate length of casing put down was 692 ft. The aggregate length of casing driven through hard material was 406.6 ft. The aggregate length of borings in shale was 86 ft., and in limestone 226 ft. The cost was as follows:

Labor	\$ 456.16
Coal	124.41
Depreciation of borts, estimated.....	200.00
Scow	287.24
Depreciation on tools, pipe, etc.....	200.00
	<hr/>
	\$1,267.81

The scow still has a value which is somewhat uncertain. Omitting this credit, the cost amounted to \$1.83 per ft.

Costs of Making Test Borings, Ill., Etc.*—Despite the wide use of test borings few engineers or contractors seem to have taken the trouble to amass data on the cost of making them, at least few such data can be found in print. The records which we give here are from scattered sources and are less complete than could be wished, but in default of better, they are of interest.

The several prices of work of which costs are given were done with a No. 80 Pierce tubular well and test boring rig. This machine consists of a base on which sets four uprights serving as guides for the driving hammers and the pipe. In operation the base is set up

**Engineering-Contracting*, Dec. 26, 1906.

level and the hammer is set on it. The four guides are then fastened in position. The whole machine is then laid over sidewise on the ground, the head casting is placed and the hoisting cable is connected up. The assembled machine is then lifted to a vertical position and is ready for work. The first section of pipe with the steel cutting shoe attached is then put in position by raising the hammer and attaching the pipe guide clamps. The pipe is then driven by raising and dropping the hammer exactly as in driving a pile. The pipe being driven, the upper part of the machine is slid rearward on the base so as to clear the pipe and a 2-in. discharge tee is screwed to the top of the pipe. The drill with water discharge holes near the bottom and the hollow drill rod are inserted in the pipe and the top of the drill rod is connected by hose to a hand pump. One man then pumps water down the hollow drill rod while another churns the drill up and down to chip and loosen the material which is carried upward through the annular space between pipe and rod and discharged into a pail so that samples can be taken. A second joint of pipe is then screwed on and driven and the drilling and working out process is repeated. In this way by alternate drilling and driving the boring is carried to the required depth. The next step is to take out the pipe so that it can be used for a second hole; this is accomplished by means of a screw jack apparatus. With the No. 80 machine a 2-in. pipe in 5 ft. sections is used. The limit of drilling of this rig is considered to be about 125 ft., for deeper holes a heavier rig is employed.

Illinois and Desplaines Rivers Survey.—In making surveys, plans and estimates for a 14-ft. waterway from Lockport, Ill., by the Desplaines, Illinois and Mississippi rivers to St. Louis, Mo., test borings were made along the route. From the official report of this work submitted to the U. S. Government and from additional data sent us by Mr. J. W. Woerman, of Peoria, Ill., who was Assistant Engineer in charge of the work from Lockport, Ill., to the mouth of the Illinois River, we have prepared the following description of the test boring work.

On one of the quarter boats a well was cut through the rake at one end through which to operate the boring machine. A 10x10-in. x22 ft. spud was provided at each corner of the boat to hold it fast while drilling. An office and living quarters for the crew and a blacksmith shop were installed on the boat. The machine used to make the borings was a "Pierce test boring rig No. 80." It consisted essentially of a 2-in. outer pipe, or casing, and $\frac{3}{4}$ -in. inner pipe or drill, with arrangements for forcing them into the ground. Water was forced down the smaller pipe, and came up again between the two pipes, carrying with it, in suspension, the material from the bottom of the river. The casing was made of extra strong wrought iron pipe, screwed together in 5-ft. lengths as it was driven down by a 200-lb. hammer. The hammer had a maximum fall of 8 ft., and was kept in line over the casing by four iron guides. It was raised with a small hand winch. The drill was made of light wrought iron pipe, to the top of which was attached a $1\frac{1}{2}$ -in. hose connected with a steam deck pump on the towboat.

A hand pump, furnished with the boring machine, was used only when it was necessary to send the towboat away from the boring boat. The drill was churned up and down by hand, when the outer casing was not being driven, and the material which came up between the two pipes escaped through a tee connection at the top of the large pipe. Samples were taken frequently by catching portions of this mixture in pails and allowing it to settle. In order to make the casing drive easily the drill was kept from 3 to 5 ft. in advance of the casing, and any change in material was noted as the drill entered it.

The borings were made in or near the channel, to a depth of about 30 ft. below low water. This was done because, when the boring boat was anchored and the machine was in operation, it cost but very little more to go 30 ft. than to stop at the proposed depth of 14 ft., and the additional information may prove valuable at some future time. As a rule the borings were spaced about half a mile apart, but if rock was encountered, or if there was any other decided change in the character of the bottom, the holes were placed close enough together to define the limits of the material. The work of making borings in the river bed was completed on July 2, 1904, and the party disbanded.

The materials penetrated were mud, sand, gravel, clay, shells, soapstone, coal and various mixtures of the above materials. When the boring reached bed rock it was necessary to stop. Bed rock was not struck very often, however, and when it was, additional borings were made in the vicinity to be sure that the drill was not in a boulder instead.

The boring party consisted of ten men who were furnished with quarters and subsistence which cost about \$15 per month per man. The wages paid the members of the party were as follows:

	Rate per month.
1 civil engineer in charge.....	\$125.00
1 pilot	75.00
1 steam engineer	75.00
1 fireman	50.00
1 cook	50.00
1 blacksmith	45.00
1 night watchman	35.00
3 laborers, at \$35.00.....	105.00
<hr/> 10 men	<hr/> \$560.00

In addition to the above wages there were also charged against the work various other expenses as indicated in the following paragraph from the official report:

"The cost of subsistence, while the men were on the quarter boats, has been charged to the various parties, according to the number of men in each party. When parties boarded away from the quarter boats, the amounts of their board bills were charged directly to that branch of the work upon which they were then engaged. The cost of the construction and equipment of the quarter boats, the cost of instruments, tools, office furniture, etc., was also charged pro rata to the various branches of the work. This was

done in order to make the total cost agree with the actual amount expended on the survey, but as this is not done usually, it should be taken into account in making comparisons with the cost of any other surveys. These items amounted to about \$18,000, or more than one-tenth of the total amount expended. These articles are all in good condition and will give good service for many years to come. The cost figures given also include a portion of the expenses of the Chicago office, as well as all expenses connected with the Peoria office."

With all the above charges included the cost of making test borings on this survey was:

Total cost	\$7,797.00
Cost, per hole.....	13.70
Cost, per lin. ft. of hole.....	0.42

Erie R. R.—A record of four weeks' work, Nov. 7 to Nov. 28, inclusive, on the Erie R. R., gives the following figures:

Superintendent, 18 half days, at \$5.....	\$ 45.00
Foreman, 19 days, at \$2.50.....	47.50
Laborers, 41 days, at \$2.00.....	82.00
Total	\$174.50

The total depth of hole bored was 699.1 ft. The labor cost of making the borings was, therefore, 24.9 cts. per lineal foot of hole. The holes were bored through sandy red clay.

New York Central & Hudson River R. R.—Two test borings were made 90 ft. deep in one day in February, 1905, for some work being done by the New York Central & Hudson River R. R. The borings were made in one case through 3 ft. of frozen ground and in the other case through 3 ft. of ice, moving the machine 600 ft. from one hole to the other. Both borings were made in one day at a total labor cost of \$5 or 2½ cts. per lineal foot of hole.

Cost of Test Borings with Wood Augers.*—Mr. A. C. D. Blanchard is author of the following:

The borings enumerated below were made in the city of Toronto during the last year in order to find the character of the soil to a depth of from 30 to 70 ft. These borings were made in connection with several works which were about to be built, and were taken in different parts of the city. The ground met with consisted chiefly of blue clay, although seven borings were made in wet, sandy clay, and four were made in filled ground. The average length of holes is shown for each locality. The borings were all made with a 1½-in. carpenter's machine auger, welded to the end of a ¾-in. pipe. The ¾-in. pipe was cut in sections 6 ft. long, and each length was added as it became necessary.

In the process of boring the auger was turned by two or three men with Stillson wrenches, at the surface. The heavier clay required three men to turn the auger. After the auger had bored from 8 to 12 ins. it had to be removed from the hole and cleaned

*A paper in *Engineering-Contracting*, Aug. 11, 1909, reprinted from "The Canadian Engineer."

and then replaced in the hole, and continued for another auger length. Considerable time was thus lost in having to remove the auger and getting it back to its position again, especially after the hole became quite deep. Samples were taken from each boring and bottled.

The force consisted of one recorder and three laborers each at \$2 a day. The work was done at all seasons of the year, and no time was lost by any of the men. The cost of blacksmith work and teaming amounted to about 5 per cent of the total cost, and the cost of material, such as augers, wrenches and iron pipe, amounted to about 10 per cent. The following is a statement of the itemized cost of the work:

(1) HEAVY BLUE CLAY: 10 INS. OF RED CLAY ON TOP.

Number of holes.....	28	
Total depth, ft.....	709	
Average depth of hole, ft.....	25.3	
Cost.....	Total.	Per ft.
Labor	\$192	\$0.281
Materials and blacksmith.....	34	0.048
Total	\$233	\$0.829

(2) MADE GROUND.

Number of holes	4	
Total depth, ft.....	90	
Average depth of hole, ft.....	22.5	
Cost.....	Total.	Per ft.
Labor	\$ 44	\$0.488
Materials and blacksmith.....	5	0.066
Total	\$ 49	\$0.554

(3) FINE, RUNNING, CLAYEY SAND.

Number of holes.....	36	
Total depth, ft.....	1,162	
Average depth of hole, ft.....	32.3	
Cost.....	Total.	Per ft.
Labor	\$293	\$0.252
Materials and blacksmith.....	43	0.037
Total	\$336	\$0.289

(4) HEAVY CLAY.

Number of holes.....	7	
Total depth, ft.....	152	
Average depth of hole, ft.....	21.7	
Cost.....	Total.	Per ft.
Labor	\$ 48	\$0.316
Materials and blacksmith.....	9	0.059
Total	\$ 57	\$0.347

(5) HEAVY BLUE CLAY.

Number of holes.....	6	
Total depth, ft.....	160	
Average depth of holes.....	26.7	
Cost.....	Total.	Per ft.
Labor	\$ 40	\$0.250
Materials and blacksmith.....	6	0.038
Total	\$ 46	\$0.288

Cost of Drilling Test Holes with a Well Driller.*—This drilling was done with a Star drilling machine (well drilling type) to test the site of a double track, steel trestle for concrete pedestal foundations. Seven holes were put down for a total depth of 190 ft. through clay and gravel to solid rock. The average depth of soil was 22 ft. and the average penetration into rock was 4 ft. The actual time consumed in drilling and moving from one hole to another was 11½ days and the total distance over which the drill was moved was 720 ft. The average time per foot of hole drilled, including moving, was 30 mins. The contractor furnished the drill and labor at cost plus 10 per cent on labor, and his bill was as follows:

	Rate.	Total.	Ft.
Driller, 11½ days.....	\$3.50	\$40.25	\$0.212
Helper, 11½ days.....	1.75	20.13	.106
Teaming, 2.1 days.....	4.00	8.10	.044
Labor, 10 days.....	1.75	17.50	.092
Use of drill, 11½ days.....	2.00	23.00	.121
Coal, 45 bushels.....	.08	3.60	.018
4½-in. casing, 54½ ft.....	.35	19.13	.100
Teaming 1 day for other parties.....	..	4.00	.021
10% for supt. and use of tools as above...	..	8.63	.046
Total		\$144.64	\$0.760

The above cost does not include any charge for inspection, as the regular inspector for the railroad company had to be on the ground to watch other work and could easily keep track of the drilling. For the above information we are indebted to H. M. Chapin, Resident Engineer, F. & C. R. R.

Cost of Diamond Drilling, Cross-References.—The foregoing data relate to costs of test borings through earth. For similar test borings in rock, see the section on Rock Excavation, under Diamond Drilling.

Cost of Sinking a Well.†—Mr. Daniel J. Hauer is author of the following:

The well was driven in a rolling country, where rock does not occur. The materials through which it was sunk were stiff red clay and sand. A tidewater marsh adjoining the site of the well furnished a poor quality of water to start the sinking of the drill, the hydraulic method being used. All remarks made by the writer will be regarding driven wells. The distinction being made from open wells, large enough for a man to enter.

These machines are generally mounted on wheels, with a mast on one end. This mast is jointed about 6 ft. from the base, so as to admit of it being lowered on to the bed of the machine, when it is necessary to move from one job to another. When the machine is in use the mast is upright and is guyed and held in place by two brace rods or timbers bolted to it near the top. The bit used on such a machine is solid and "the string of tools" consisted of rods, one end being a socket and the other a bolt end, all

*Engineering-Contracting, Mar. 4, 1903.

†Engineering-Contracting, May 23, 1906.

threads. The top piece has a "rope socket" on the upper end, used to attach it to the machine. With such a well boring apparatus, the hole must be cleaned when a depth of from 2 ft. to 5 ft. has been obtained. This necessitates removing the boring tools and pumping out the debris or "sludge" with a sand pump, all of which consumes a large amount of time, especially if the well is driven to a depth greater than 100 ft. The hydraulic method of driving wells obviates the use of the sand pump, and in wells of any depth, through soft material, is preferable to the other method.

Driven wells are usually from 6 ins. to 16 ins. in diameter. A hole less than 6 ins. cannot be driven to any great depth as the tools would have to be so light as to run grave chances of breaking them. Fifteen and sixteen-inch holes are the maximum at present, owing to the fact that these seem to be the sizes of the pipes for casing, that are made economically and are easily placed in the well. Many manufacturing plants are using twelve and fourteen-inch wells.

When the hydraulic method is used a square pyramidal derrick from 40 ft. to 70 ft. in height is erected. Timber is used for these structures by well drilling contractors, but the writer sees no reason why a tower, modeled after those used by prospectors in taking ore drillings, and made of steel, could not be used and taken down after each job and moved to a new site. Of course, the timber can be used more than once, but each time some of it is used up and all of it has to be renewed after several jobs. The life of a steel derrick, if kept painted, would be many years, and only the bolts would have to be renewed from time to time. The tools differ somewhat from those previously described. The bit is hollow, with a hole just above the cutting point on either side to allow the jet of water to enter the well. Instead of rods, pipes are used, and the rope socket has an attachment to which is fastened the hose, run from the pump to the drilling column.

The well in this case was 8 ins. in diameter. The derrick was 60 ft. high. The first deck was 20 ft., while the three upper decks were each 10 ft. The head blocks carried a sheave. On one side of the derrick was a ladder. On the other side was fastened the windlass and gearing. The corner posts of the derrick were 4 x 6 in. timbers, while the braces were 2 x 8 in. and 1 x 12 in. planks; the head blocks were 4 x 6. Twenty-five hundred feet board measure of timber was used for the derrick and about 500 ft. for a tool house and other needs. The outfit consisted of the following: An upright boiler and engine on separate bases, a steam duplex pump, two hand pumps, windlass and gearing, two hammers for driving well casing, ropes and blocks, drill points, hard rubber hose, wrenches of various kinds, pipe cutters and dies, and various small tools. Several tents for the workmen to live in while driving the well, and bedding and cooking utensils were also included in the outfit. The approximate value of this outfit, when new, was \$1,000. Allowing 25 per cent per year for interest and depreciation, and considering 100 work days as covering a season's work for an out-

It, we have a daily plant charge of \$5.00. This is small considering the hard usage the plant undergoes. The boiler has all kinds of water used in it, which quickly injures the tubes. The pumps also fare roughly from the pumping of water saturated with the debris from the well, the water being used over and over again. The continual handling of the pipe soon wears out the threads, necessitating cutting and making new threads, and so it is with other details of the outfit, all of which quickly takes money for renewals and repairs. As a large percentage of wells are driven in inaccessible parts of the country, a well driving contractor must carry with him every tool that any emergency may demand.

In the work which the writer is describing five days were consumed by two men in erecting the derrick and setting up the plant. Then a length of 12-in. pipe was sunk to protect the mouth of the well, after which the well driving commenced. As stated above, water to start the work was used from an adjoining swamp. The first day's driving resulted in a depth of over 50 ft. and gave enough water to continue the work. The average depth obtained each day of actual driving was 20 ft., but the average for the total time consumed in working on the well was a fraction over 11 ft. The well was sunk to a depth of 229½ ft., when sufficient water was obtained to fulfil the terms of the contract. At 260 ft. a stratum of sand was struck and the well was cased up and tested, but as the vein of sand was not over 3 ft., it did not give sufficient water and the driving was continued. At a depth of 318 ft. sand was again encountered, and again the well was cased up and the strainer put in place and the well tested, the strainer being located at the depth given above. No effort was made to obtain the depth of this stratum of water bearing sand.

Seventeen days were consumed in driving the well, and five days in casing up, placing the strainer and testing. One day sufficed to dismantle the plant and haul it away. As the outfit was on the road two days, two additional days are included in the plant charge. Three and one-half tons of coal were used, there being a daily consumption of 220 lbs. The cost of this, including hauling, was \$5.25.

The crew consisted of one experienced drill driver, who acted as foreman when the contractor was absent, and two laborers, both of whom had had some experience in driving artesian wells. The derrick was built and the machinery placed by the foreman and one laborer, the second laborer coming on the work only after the well driving began. At all critical stages of the work a member of the contracting firm took charge of the forces and worked with the rest of the crew, doing whatever came to hand. In all he worked in this manner seven days. In the record of cost given an allowance of \$2.50 is made for each of these days' work. The rates of wages or their equivalent for the other men were as follows:

Well driver	\$2.75
Laborers	2.00

The wages were paid weekly and included board; but the figures

given show, the daily cost for ten hours' work to the contractor, made up from a season's employment. All of the men were paid full time, and frequently were called to make over-time without additional pay. Well driving can be done during wet weather without serious inconvenience to the men, as they seldom stop except in steady downpours of rain. This is made possible by only a few men being employed; with a large number, a few become dissatisfied and the whole force is stopped.

The itemized cost of the well, for both labor and materials, except the strainer, was as follows:

Labor:

Erecting derrick and machinery.....	\$ 23.75
Driving well and casing.....	170.75
Pumping and testing well.....	12.25
Tearing down derrick, etc.....	6.75

Total labor\$213.50

Materials:

3½ tons of coal, at \$5.25.....	\$18.37
Pipe casing, 340 ft., at \$0.86.....	292.40
Outer casing (second hand).....	10.00
Derrick timber, 3,000 ft. B. M., at \$25.00.....	75.00

Total materials\$395.77

Miscellaneous:

Transportation charges	\$100.00
Plant rental, 30 days, at \$5.00.....	150.00
Superintendence and general expenses.....	50.00

Total miscellaneous\$300.00

Grand total\$909.27

The transportation charge is for both freight by train and hauling by wagons to and from the job, and is a little higher than usual. The figures giving a cost per lineal foot of well are as follows:

Labor	\$0.63
Materials	1.14
Miscellaneous	0.88
Total	\$2.67

It is of interest to note that the cost of fuel, which is high per ton, amounts to a fraction over 6 cts. per foot of driven well, which is a comparatively small cost. The full charge is made against this job for the derrick timber, although some of it had been used previously and all of it was hauled away to be used on another job.

The boiler was fired by the man attending to the pumps or else the man running the windlass. The consumption of coal might have been reduced somewhat by the boiler having a cheap house over it and the steam pipes being covered. On a single job like this but little saving would be shown, but in a year or two the additional cost would be more than saved. With a small boiler a house could be constructed readily in sections and moved from job to job. The steam pipes could also be lagged and handled in the same manner. The writer feels confident that these are details well

work considering not only in well driving, but also on much other construction work.

The contractor doing this work owns three such outfits, and in spite of the fact that three or four men can operate each plant, he states that it is exceedingly difficult to obtain men to put in charge of a plant; men who can be relied upon to face any crisis in the work and handle it without a money loss. For these reasons he seldom runs but two machines, as he can give these his personal attention and only keeps the third plant for an emergency. That is, to take a job from an old customer, that may go to a competitor, or land new work that is exceedingly desirable. Margins are so close that a single mistake of judgment may use up the entire profit of a job.

After pumping this well, the sinking of which has just been described, for 24 hours the flow was tested and found to be 80 gallons per minute. The water level had only been reduced 10 ft. by this pumping. The strainer was placed 340 ft. below the level of the ground, the elevation of the latter being 5 ft. above mean low tide. The strainer used was made from a piece of pipe plugged at one end and punched with holes, the dimensions of which were $\frac{1}{2}$ in. x $\frac{1}{2}$ in.

The placing of the strainer and the variety of strainer used is a matter of vast importance and every detail regarding it should be specifically stated in a contract for a driven well. All too frequently this is not done, and the entire matter is left in the hands of the contractor, who only sees that the well comes up to the required tests and that a strainer is properly placed in the well. The kind he will use will be the style he is accustomed to, which may not be suitable for the well in question.

Strainers, of which there are a number of styles patented and used, may be classed as either fine or coarse. The majority of the older patents are for fine strainers, that is, the openings are made so small as to admit of water entering the pipe and yet stop the finest sand. The slots are cut larger on the inside than on the outside of the pipe, so as to allow any grains of sand that may enter the opening to go into the strainer and not clog the hole. The openings in fine strainers are less than $1/60$ in. in size. It is evident that with little corrosion or rust these holes will become closed and the entire well rendered useless. In the coarse strainers this will neither happen as often or as soon, hence they are preferable. The main objection to this class of strainers is that they will gradually fill with sand and thus stop the flow. This can be obviated. If the grains of sand were of equal size in water bearing sand, we would only need to have openings of such a size as to not admit the grains and the difficulty would be solved, but as a rule the grains of water bearing sand not only vary greatly in size, but also contain some gravel.

When gravel is not carried by the sand some should be placed around the strainer by artificial means. Then the well should be pumped at a rapid rate for such a length of time as may be neces-

sary to draw in all the fine sand that may ultimately be disturbed by the velocity of the water. When this is done and the sand cleaned out of the well, and the coarse strainer properly placed, no trouble should occur from this source. At times it may be found necessary to use air pressure to agitate the fine sand, as the pumping is going on, so as to facilitate the drawing in of the fine particles. Trouble will only occur when the inflow of water is of such velocity as to carry the fine fluid with it.

These operations are rather costly and it cannot be expected that the contractor will do them, unless they have been previously specified, so that his price is made to cover them. The engineer should see to this. Many wells that have to be reworked only needed these things done when they were driven. The costs that have been given do not include any work of this nature.

(For further data on well driving, see the index under Wells.)

References and Cross-References on Earthwork.—For cost data on dredging, hydraulicking earth, and costs by many other methods of excavation, the reader is referred to my book on earthwork. In various sections of this book will be found other data on earthwork costs, for which consult the index under "Excavation, Earth."

SECTION III.

ROCK EXCAVATION, QUARRYING AND CRUSHING.

Weight and Voids.—Civil engineers commonly measure rock excavation by the cubic yard in place before loosening, whereas mining engineers generally use the ton of 2,000 pounds as the unit of rock and ore measurement. In view of this fact it would be well were the specific gravity of the rock given by every engineer who publishes data on any particular kind of rock excavation or mining. Then, too, it often happens that broken rock is purchased by the ton even for civil engineering work, or by the cord of loosely piled rubble for architectural work, thus emphasizing the importance of stating not only the specific gravity but the percentage of voids.

The specific gravity of any material is the quotient found by dividing its weight by the weight of an equal bulk of water. Water, therefore, has a specific gravity of 1; a cubic foot of any substance like granite, having a specific gravity of 2.65, weighs 2.65 times as much as a cubic foot of water. A cubic foot of water weighs 62.355 lbs., or practically 62.4 lbs., hence a cubic foot of solid granite weighs, $62.4 \times 2.65 = 165.3$ lbs.

When any rock is crushed or broken into fragments of tolerably uniform size it increases in bulk, and is found to have 25% to 55% voids or inter-spaces, depending upon the uniformity of the fragments and their angularity. Rounded fragments, like pebbles, pack more closely together than sharp-edged or angular fragments. A tumbler full of bird shot has about 35% voids, and it is possible to hand-pack marbles of uniform size so that the voids are only 25%. Obviously, if small fragments of stone are mixed with large fragments, the voids are reduced. Pit sand ordinarily has 35% to 40% voids. Hard broken stone from a rock crusher has about 35% voids if all sizes are mixed and slightly shaken down in a box; whereas, if it is screened into several sizes, each size has about 45% to 48% voids.

A soft and friable rock like shale breaks into fragments having a great range in size, from large chunks down to dust; and, as a consequence, such soft broken rocks have a much lower percentage of voids than the tougher rocks.

The following table shows the swelling of rock upon breaking:

Voids	30%	35%	40%	45%	50%	55%
Cu. yds. broken rock from 1 cu. yd. solid rock....	1.42	1.54	1.67	1.82	2.00	2.22

TABLE III.

Specific Gravity.	Weight in Lbs. per cu. ft.	Weight in Lbs. per cu. yd.	Weight in Lbs. per cu. yd. when Voids are				
			30%	35%	40%	45%	50%

TABLE IV.—VOIDS IN LOOSE BROKEN STONE.

Authority.	Per cent Voids.	Remarks.
Sabin	49.0	Limestone, crusher run after screening out $\frac{1}{2}$ -in. and under.
Sabin	44.0	Limestone (1 part screenings mixed with 6 parts broken stone).
Wm. M. Black.....	46.5	Screened and washed, 2 ins. and under.
J. J. R. Cross.....	47.5	Gneiss, after screening out $\frac{1}{2}$ -in. and under.
S. B. Newberry.....	47.0	Chiefly about egg size.
H. P. Boardman.....	39 to 42	Chicago limestone, crusher run.
H. P. Boardman.....	48 to 52	Chicago limestone, screened into sizes.
Wm. M. Hall.....	48.0	Green River limestone, 2 $\frac{1}{2}$ ins. and smaller, dust screened out.
Wm. M. Hall.....	50.0	Hudson River trap, 2 $\frac{1}{2}$ ins. and smaller, dust screened out.
Wm. B. Fuller.....	47.4	New Jersey trap, crusher run, 1/8 to 2.1 in.
Geo. A. Kimball.....	49.5	Roxbury conglomerate, $\frac{1}{2}$ to 2 $\frac{1}{2}$ ins.
Myron S. Falk.....	48.0	Limestone, $\frac{1}{4}$ to 3 ins.
W. H. Henby.....	43.0	Limestone, 2-in. size.
W. H. Henby.....	46.0	Limestone, 1 $\frac{1}{2}$ -in. size.
Feret	53.4	Stone, 1.6 to 2.4 in.
Feret	51.7	Stone, 0.8 to 1.6 in.
Feret	52.1	Stone, 0.4 to 0.8 in.
A. W. Dow.....	45.3	Bluestone, 89% being 1 $\frac{1}{2}$ to 2 $\frac{1}{2}$ in.
A. W. Dow.....	45.3	Bluestone, 90% being 1/8 to 1 $\frac{1}{2}$ in.
Taylor and Thompson	54.5	Trap, hard, 1 to 2 $\frac{1}{2}$ ins.
Taylor and Thompson	54.5	Trap, hard, $\frac{1}{2}$ to 1 in.
Taylor and Thompson	45.0	Trap, hard, 0 to 2 $\frac{1}{2}$ ins.
Taylor and Thompson	51.2	Trap, soft, $\frac{1}{4}$ to 2 ins.
G. W. Chandler.....	40.0	Canton, Ill.
Emile Low	39.0	Buffalo limestone, crusher run, dust in.
C. M. Saville.....	46.0	Crushed cobblestone, screened into sizes.
I. O. Baker.....	43 to 47	Crushed limestone in sizes.
A. N. Johnson.....	41 to 51	Crushed limestone in sizes.
W. E. McClintock....	47.0	Crushed trap.

The following records of actual tests will indicate the range of void percentages:

Prof. S. B. Newberry gives the voids in Sandusky Bay gravel, $\frac{1}{4}$ to $\frac{1}{2}$ -in. size, as being 42.4% voids; $\frac{1}{4}$ to $1/20$ -in. size, 35.9% voids.

Mr. William M. Hall, M. Am. Soc. C. E., gives the following tests on mixtures of Green River, Ky., blue limestone and Ohio River washed gravel:

Stone.		Gravel.	Voids in Mixture.
100%	with	0%	48%
80	"	20	44
70	"	30	41
60	"	40	38 $\frac{1}{2}$
50	"	50	36
0	"	100	35

The stone passed a $2\frac{1}{2}$ -in. screen and the dust was removed by a fine screen. The gravel passed a $1\frac{1}{2}$ -in. screen.

The voids in mixtures of Hudson River trap rock and clean gravel, of the sizes just given for the Kentucky materials, were as follows:

Trap.		Gravel.	Voids in Mixture.
100%	with	0%	50%
60	"	40	38 $\frac{1}{4}$
50	"	50	36
0	"	100	35

Mr. H. von Schon gives tests on a gravel having 34.1% voids as follows:

	Per cent.
Retained on 1-in. ring	10.70
Retained on $\frac{3}{4}$ -in. ring	23.65
Retained on No. 4 sieve	8.70
Retained on No. 10 sieve	17.14
Retained on No. 20 sieve	21.76
Retained on No. 30 sieve	6.49
Retained on No. 40 sieve	5.96
Passed No. 40 sieve	5.59
Passed $1\frac{1}{2}$ -in. ring	100.00

Feret gives the following results of tests on mixtures of different sizes of pebbles, and mixtures of different sizes of stone (the stone and pebbles were not mixed together):

					Voids in	
Passing a	ring of...	2.4"	1.6"	0.8"	Round	Broken
Held by a	ring.....	1.6"	0.8"	0.4"	Pebbles.	Stone.
Parts	1	0	0	40.0%	53.4%
"	0	1	0	38.8	51.7
"	0	0	1	41.7	52.1
"	1	1	0	35.8	50.5
"	1	0	1	36.6	47.1
"	0	1	1	37.9	49.5
"	1	1	1	35.5	47.8
"	4	1	1	34.5	49.2
"	1	4	1	36.6	49.4
"	1	1	4	38.1	48.6
"	8	0	2	34.1	

Mr. A. W. Dow gives the following tests on mixtures of broken stone and gravel at Washington, D. C.:

—Parts of Broken Bluestone—			—Parts of Gravel—		
Granolithic (82% being 1/10 to 1/4")	Coarse (89% being 1/2 to 2 1/2")	Average (90% being 1/2 to 2")	Average (90% being 1/6 to 1 1/2")	Small (80% being 1/4 to 1/2")	Voids, Per cent.
....	1	45.8
....	1	45.8
1	1	39.6
....	1	39.8
....	1	1	35.6
....	2	1	36.7

Taylor and Thompson give the following:

Ref. No.	Stone.	Size.	Voids in loose stone.	Per cent Compression by light ramming or shaking.	Per cent Voids after light ramming.	Per cent Compression by heavy ramming.	Per cent Voids after heavy ramming.
1....	Hard trap	2 1/2" to 1"	54.5	19.2	43.7
2....	Hard trap	1" to 1/2"	54.6	14.3	46.9	29.6	43.8
3....	Hard trap	2 1/2" to 0	45.0	14.5	35.7	20.8	30.6
4....	Soft trap	2" to 1/2"	51.3	11.9	44.4	17.8	40.6
5....	Soft trap	3/4" to 1/8"	51.2	14.8	43.1	23.9	35.9
6....	Gravel	2 1/2" to 1/2"	36.5	12.5	27.4	11.6	28.2

The stone was thrown into a measuring box and measured, then rammed in 8-in. layers. The variation in the last column for Nos. 4 and 5 was due to the breaking of the trap under the rammer. No. 3 was "crusher run" containing 44.4% of No. 1, 33.3% of No. 2, and 22% of screenings from 1/2-in. down to dust. Nos. 1, 2 and 3 were crushed in a gyratory crusher; Nos. 4 and 5, in a jaw crusher.

Mr. George W. Rafter gives the voids in clean limestone, broken (by hand?) to pass a 2 1/2-in. ring, as 42% after being "slightly shaken," and 37 1/2% after being rammed.

Mr. Desmond Fitzgerald states that broken stone dropped 12 ft. into a car measured 7% less in volume after the fall.

As originally pointed out in my "Rock Excavation," I have found that a wagon load of broken stone measures 10% less in volume after it has traveled a short distance, due to the shaking down. In buying broken stone by the cubic yard it is well to bear this fact in mind.

Percentages of voids in sand are given in the section on Concrete. Consult the index under "Sand, Voids."

Sizes and Weight of Crushed Trap.—Mr. William E. McClintock gives the following data relative to Massachusetts trap rock: The rock weighs 180.7 lbs. per cu. ft. solid, or 4,879 lbs. per cu. yd. solid, being very heavy. The crushed trap of the Mass. Broken Stone Co., at Salem, weighs 2,586 lbs. per cu. yd., and has 47%

voids. A rotary screen is used 10 ft. long, 40 ins. diameter, with three sections $2\frac{1}{2}$ ft., 2 ft. and 3 ft. long respectively, having circular holes $\frac{1}{2}$ -in., $1\frac{1}{2}$ ins. and 3 ins. diameter. A bin holding 29 cu. yds. was used to measure the $\frac{1}{2}$ -in. screenings which were afterward weighed and found to average 2,605 lbs. per cu. yd. A box holding 1 cu. yd. was packed full with wet screenings which weighed only 2,480 lbs. The same box packed full of the same kind of screenings dry was found to hold 2,690 lbs. A bin holding 90 cu. yds. of the $1\frac{1}{2}$ -in. stone averaged 2,423 lbs. per cu. yd.; and a bin of the same size full of 3-in. stone, averaged 2,522 lbs. per cu. yd. This 3-in. stone was again measured in cars, and found to average 2,531 lbs. per cu. yd.

To determine the percentages of the different sizes, 19 cu. yds. of broken stone were measured and found to run as follows:

	Percent
$\frac{1}{2}$ -in. trap	13.24
$1\frac{1}{2}$ -in. trap	23.89
3-in. trap	62.87
Total	100.00

The tailings over 3 ins. in size were re-crushed.

Weight and Voids of Crushed Limestone.*—In 1906 the State Highway Commission of Illinois had a series of tests made at the state stone crushing plants at Menard and Joliet to determine what should be called a cubic yard of crushed stone. The results of these tests are given by Mr. A. N. Johnson, State Engineer. In making the tests both cars and wagons were loaded in different ways and hauled different distances. The contents of each car or wagon were carefully measured and weighed, and on arrival at destination again measured, so that the variation in the density of the load due to method of loading, to size of material and to settlement, was determined. From the results of these tests it will be seen that the average weight of the wagon loads of limestone, including all sizes, was, at the start, very nearly 2,400 lbs. per cubic yard, varying somewhat according to the method of loading, and that the weight of a cubic yard in a wagon after it had been hauled a distance of one-half mile was a little over 2,500 lbs. Also, that the weight of a cubic yard of stone, as loaded in the cars, is but a few pounds over 2,400 and after settlement 2,600 lbs. As the weight of a cubic yard depends very considerably on the method of loading the car or wagon, and also as to the amount of settlement due to the length and character of the haul, the determination of what shall be the weight of a cubic yard is somewhat arbitrary. In view of the results of these tests, the State Highway Commission has adopted 2,500 lbs. as the weight of a cubic yard of crushed limestone at both the Menard and Joliet crushers.

**Engineering-Contracting*, Apr. 3 and 10, 1907.

In the following tabulation is shown the weight per cubic yard of crushed limestone in carload lots and per cent of settlement in transportation, the haul in each instance being about 150 miles:

Size in inches.	Method of loading.	Weight in pounds per cubic yard when shipped.	Per cent of settlement.
Screenings,	15 ft. drop.....	2,500	9.5
"	"	2,509	12.5
"	"	2,530	9.8
3	Wheelbarrows.....	2,476	3.4
"	"	2,820	8.2
"	15 ft. drop.....	2,528	9.5
Screenings,	8 ft. drop.....	2,520	9.0
"	"	2,520	...
"	"	2,780	8.3
"	"	2,610	12.5
"	"	2,680	8.3
1 1/2	"	2,570	1.4
"	"	2,310	13.9
"	"	2,360	8.7
"	"	2,300	13.6
"	"	2,180	7.4
"	"	2,200	9.7
"	"	2,250	7.7
2	"	2,520	3.8
"	"	2,440	3.4
"	"	2,500	5.0
"	"	2,380	12.9
"	"	2,300	3.7
"	"	2,400	0.0
"	"	2,290	9.0
"	"	2,270	7.4
"	"	2,275	9.2
"	"	2,240	11.1
"	"	2,260	10.5
"	"	2,470

To determine the effect of manner of loading, other experiments were made. In some experiments a box measuring 2.8 cu. ft. was used. No difference in the results, however, due to the size of the box could be detected. In every instance the voids were determined by weighing the amount of water added to fill the box. The tabulation is as follows:

Size.	Method of Loading.	Per cent of Voids.
3 in.	20-ft. drop	41.8
2 in.	15-ft. drop	46.8
3 in.	15-ft. drop	47.2
3 in.	shovels	48.7
1 1/2 in.	20-ft. drop	42.5
1 1/2 in.	15-ft. drop	46.8
1 1/2 in.	15-ft. drop	46.8
1 1/2 in.	shovels	50.5
1 1/2 in.	20-ft. drop	39.4
1 1/2 in.	15-ft. drop	42.7
1 1/2 in.	15-ft. drop	41.5
1 1/2 in.	15-ft. drop	41.8
1 1/2 in.	shovels	45.2
1 1/2 in.	shovels	44.6
1 1/2 in.	shovels	41.0
1 1/2 in.	shovels	40.6
1 1/2 in.	shovels	41.0

Settlement of Crushed Stone in Wagons.*—The tests, the results of which are shown below, were made by the Illinois Highway Commission to determine the settlement of crushed stone in wagon loads for different hauls. The road over which the tests were made is a macadam road, not particularly smooth, but might be considered as an average road surface. The wagon used was one with a dump bottom supported by chains, which were drawn as tight as possible, so as to reduce the sag to a minimum. It will be noticed that about 50 per cent of the settlement occurs within the first 100 ft., and 75 per cent of the settlement in the first 200 ft. Almost all of the settlement occurs during the first half mile, as the tests showed practically no additional settlement for distances beyond.

Some of the wagons were loaded from the ground with shovels, others were loaded from bins, the stone having a 15-ft. drop, which compacted the stone a little more than where loaded with shovels so that there was somewhat less settlement. But at the end of a half mile the density was practically the same, whatever the method of loading. The density at the beginning and at the end of the haul can be compared by the weight of a given volume of crushed stone. For convenience, the weight of a cubic yard of the material at the beginning of the haul and at the end was computed from the known contents of a wagon.

Table V shows the per cent of settlement of crushed limestone in wagon loads at the end of different lengths of hauls:

Weight of Crushed Stone in Wagons and Cars.—In *Engineering-Contracting*, Aug. 5, 1908, are given in detail the results of some very careful tests made by Prof. Ira O. Baker on the voids in broken limestone of various sizes and after various drops and lengths of haul in wagons and cars. The following is a very brief summary of the results.

The following were the weights of broken stone per cubic yard in wagons and in cars, both at the crusher and after hauling a given distance:

Location of quarry.	Size of stone.	Wagon Loads.		Car Loads.	
		Wt. at crusher.	After a haul of $\frac{1}{2}$ mile or more.	Wt. at crusher.	After a haul of 75 miles or more.
Joliet.....	$\frac{1}{2}$ in. Scr.	2303	2533	2659	2905
Joliet.....	$\frac{3}{4}$ in. Scr.			2652	2882
Joliet.....	2 in.- $\frac{1}{2}$ in.	2315	2480	2385	2532
Joliet.....	2 in.- $\frac{3}{4}$ in.			2296	2516
Joliet.....	3 in.-2 in.			2361	2553
Chester.....	$\frac{1}{2}$ in. Scr.	2442	2797	2544	2850
Chester.....	2 in.- $\frac{3}{4}$ in.	2344	2582		
Chester.....	3 in.-2 in.	2367	2569	2348	2546
Kankakee....	$\frac{3}{4}$ in. Scr.	2430	2697		
Kankakee....	1 $\frac{1}{2}$ in.- $\frac{3}{4}$ in.	2325	2546		
Kankakee....	2 $\frac{1}{2}$ in.- $\frac{3}{4}$ in.			2260	2390

The limestone came from Chester, Joliet and Kankakee, Ill., the specific gravity being 2.57, 2.71 and 2.61 respectively. There was

**Engineering-Contracting*, April 24, 1907.

TABLE V.

Size.	Method of loading.	Length of Haul in Feet.						$\frac{1}{4}$ mile.	1 mile.	Weight per Cubic yard in pounds. At start. At finish.

*Same per cent of settlement for two-mile haul.

no very marked variation in the voids for different sizes of stone, the range being from 43% for the 1½ to 2½-in. size of stone to 47% for screenings ¾ in. and less.

When broken stone was shoveled or dropped into a wagon, and hauled, it settled about 4% during the first 100 ft. of haul, and about 4% more during the next half mile, a total of 8%, beyond which there was no settlement. Screenings settled more, about 6% in the first 100 ft., and a total of 12% at the end of a half-mile haul. A 75-mile haul in railway cars caused no more settlement than a half-mile haul in wagons.

The Per Cent of Voids in Railway Embankment.*—One of the editors of this paper, some years ago, built a section of a railroad in the South where many of the embankments were made from borrow pits, the material being solid rock. These pits were not cross-sectioned, and the specifications stated that when excavation was measured in embankment, that it should be considered that one yard of solid rock in place would make 1.75 cu. yds. in embankment. The editor protested against this, believing he was being deprived of from 15 to 20% of his yardage, but as he could show no authentic records to disprove the engineer's claim, he was paid on the basis given in specification.

We are able to give an example when it was possible to obtain the exact yardage taken from the cut, and the amount it made in the fill. At Boulder, Colo., in 1882, a cut of 3,600 cu. yds. made an embankment of 5,349 cu. yds., which is a ratio of 1 to 1.51.

In blasting rock for excavation on railroads, the mass comes out in pieces of all sizes, and as they are placed in the embankment voids of considerable size are made between the pieces. If the excavated rock has a layer of overlying earth that has not been stripped off before the rock is blasted, much of this earth, and the rock that is ground up fine, go to fill up these voids, making the embankment more compact than where there is no dirt excavated in connection with the rock. The result is that rock by itself "swells" more than it does when excavated in connection with earth and loose rock.

The writer's experience is that with solid rock first stripped and then excavated, the example given at Boulder is a fair average; but, with rock excavated where the solid rock is excavated in connection with loose rock and earth, this ratio of expansion is too high. For the last named excavation 1 to 1.4 is about the proper ratio.

Voids in Rock Blasted Under Water.†—Mr. E. C. Bowen is author of the following:

In Dredge Section 3 of the Ashtabula Dock Extension, Lake Shore & Michigan Southern Ry., which has just been finished by the Lake Erie Dredging Co. of Buffalo, the rock dredged was paid for by place measurement, there being 62,869 cu. yds. of rock so

**Engineering-Contracting*, Sept. 25, 1907.

†*Engineering-Contracting*, Nov. 5, 1907.

measured in this section. This was determined by careful soundings taken 6 ft. apart on ranges which were parallel lines spaced 6 ft. apart, both before and after dredging. The material dredged was shale rock which had been drilled and blasted, and which, after being dumped into scows, averaged about 25 lbs. per piece, in size.

Payments were made monthly and it was found impracticable to make place measurements each month on account of the large amount of floating plant engaged on the dock extension, which was in the way, and the often rough condition of Lake Erie. It was, therefore, decided to measure the material in scows and take a certain per cent of this as place measure until the final estimate when the total amount of material in this section would be determined by soundings taken before and after dredging. The sum of all partial payments previously made would then be subtracted from the above total, giving the amount of the final estimate.

The total amount dredged as measured in scows was 103,537 cu. yds. The amount of voids in the rock was, therefore, 39.3 per cent. Excavation was paid for 6 ins. below the required grade and no excavation was found by the soundings to have been carried below this level, which was 21.5 ft. below lake level.

A large amount of this material was used below water for filling the cribs forming the substructure of the docks and it was found to pack down very solidly. When exposed to air, however, it disintegrates rapidly.

Measurement of Rock.—Rock excavation is commonly measured in place before loosening, and paid for by the cubic yard of actual excavation; but, in sewer work and in tunnel work, if the contractor excavates beyond certain "neat lines" shown in the blue-prints, no payment is made, unless the specifications explicitly provide for payment for excavation beyond these "neat lines." In trench work, for example, a contractor often has to excavate from 6 to 18 ins. below the grade shown in the blue-print, because it costs less to do so than to work too close to the grade and afterward break off projecting knobs with a bull-point or otherwise. The same is true of shallow excavation, or skimming work, in road construction and the like.

The amount of rock taken out beyond the "neat lines" is called the "overbreak." For percentages of "overbreak" in tunnel work consult the index under Tunnels.

In examining specifications care should also be taken to note whether mention is made of rock slips or falls; for it often happens that after blasting to the neat lines a huge slide of rock occurs, possibly filling the entire excavation. Who is to stand the cost of removing this slide? If it is prescribed that the contractor shall, then he should study the dip of the rock and its character with this question of sliding in mind.

A perch of masonry is commonly taken as being 25 cu. ft. (or nearly 1 cu. yd.), but the original perch was a wall 12 ins. high, 18 ins. wide, and a rod (16½ ft.) long, making 24½ cu. ft. In certain localities the "perch" is taken as being only 22 cu. ft., but in

most places in this country a perch is only $16\frac{1}{2}$ cu. ft. These facts the contractor should know, for he must often deal with quarrymen who will not sell rock by the cubic yard.

In some localities stone for building is sold by the cord. Sedimentary rock quarried in slabs that are corded up carefully by hand may have 30% or less voids, which makes it evident that a contractor in buying rock by the cord should be careful to prescribe that it be packed closely and not dumped in piles helter skelter before measurement. In buying rock by the "cord" there is another precaution to be taken, and that is to specify how many cubic feet constitute a cord. A cord of wood is $4 \times 4 \times 8 = 128$ cu. ft., but a "cord" of stone is often $1 \times 4 \times 8 = 32$ cu. ft. Rock is often purchased by the ton of 2,000 lbs.; but to avoid lawsuits it is wise to define the word "ton" in any written or verbal contract, for a ton means 2,240 lbs. in some localities.

If crushed stone for macadam or ballast is purchased by the cubic yard measured loose, the precaution of stating where the measurement is to be made should always be taken. I have made measurements of wagon loads of broken stone after loading from chutes at the bins, and again after traveling for half a mile or more. A surprising shaking down, or settlement, always takes place, ordinarily making a reduction in volume of 10%. I announced these results in 1901, and recent experimenters have confirmed this percentage very closely.

There is another caution to be taken in examining specifications and in buying stone for concrete. Note whether or not the specification requires that the largest permissible stone shall pass *in every direction* through a ring of, say, $2\frac{1}{2}$ in. diameter. I have italicized the words "in every direction" because few engineers realize and few contractors stop to think that this virtually means the use of a much smaller opening in the screen than the one specified, in this case smaller than $2\frac{1}{2}$ in. In screening stone in a rotary screen, long narrow fragments will drop through a $2\frac{1}{2}$ -in. hole, yet many of these fragments will not pass "in every direction" through a $2\frac{1}{2}$ -in. hole. On this account, small though the matter seems, I once had more than 1,000 cu. yds. of stone rejected by an inspector who found that he could not pass through a ring some of the long fragments when laid crosswise.

There are two ways of designating the sizes of stone after screening. One is to designate the stone according to the diameter of the screen hole through which it has passed; in this case stone that has passed a $2\frac{1}{2}$ -in. hole is called "two and a half inch stone." Another, and very common way, is to take the diameter of the screen hole through which the stone did not pass, add it to the diameter of the screen hole through which the stone did pass, divide this sum by two, and call this average diameter the size of the stone. Suppose, for example, that a stone crusher were provided with a rotary screen having three sections of perforated metal, the holes in the first section being $\frac{3}{4}$ -in. diameter, the holes in the second section $1\frac{1}{2}$ -in. and in the third section $2\frac{1}{2}$ -in. Then the

average size of the stone that passes the $\frac{3}{8}$ -in. holes is $\frac{3}{8}$ -in. stone (assuming it to run from dust to $\frac{3}{8}$ -in.). The average size of the stone that passes the $1\frac{1}{2}$ -in. holes but does not pass the $\frac{3}{8}$ -in. holes, is $(1\frac{1}{2} + \frac{3}{8}) \div 2$, or $1\frac{1}{8}$ -in., and it may be called $1\frac{1}{8}$ -in. stone. In like manner the stone between $1\frac{1}{2}$ -in. and $2\frac{1}{2}$ -in. may be called 2-in. stone. This rule is not followed strictly by the manufacturers of crushed stone, so it is always necessary to inquire exactly what they mean when they speak of stone of a certain size. Thus the Rockland Lake Trap Co. have the following schedule of commercial sizes:

Diameter of holes in screen, inches.	$4\frac{1}{2}$	$3\frac{1}{2}$	$2\frac{1}{2}$	$1\frac{1}{16}$	$\frac{3}{8}$
Commercial sizes of stone, inches.	$3\frac{1}{2}$	$2\frac{1}{2}$	$1\frac{1}{2}$	$\frac{3}{4}$	$\frac{1}{2}$

Therefore, when " $2\frac{1}{2}$ -in. stone" is ordered from this company, they ship a product that ranges from $2\frac{1}{4}$ ins. to $2\frac{3}{4}$ ins. in size—indeed, some of the stone fragments are even larger than $3\frac{1}{4}$ ins. in certain directions, for, as above stated, a long, narrow stone may pass through a screen.

Kinds of Hand Drills.—Drilling holes in rock by hand may be effected in three ways: (1) By a rotary drill or auger; (2) by a churn-drill; (3) by a hammer-drill, or "jumper" drill, struck with a hammer. A rock auger operated by hand is used only in very soft rock or coal.

A churn-drill, as its name implies, is raised and allowed to drop, or is hurled against the rock. For shallow holes of small diameter it is necessary to give a churn-drill additional weight, which is done by welding a ball of wrought iron to the center of the drill shank, making a ball-drill. A ball-drill is usually provided with a cutting bit at each end, and is operated by one man. For deep drilling, that is, for holes more than about $2\frac{1}{2}$ or 3 ft. deep, an ordinary churn-drill is used, operated by one man for shallow work, two men for deeper work, and three or even four men for very deep holes where the weight of metal becomes considerable.

The churn-drill in the hands of a skilled driller is the most effective type of hand drill for vertical holes; and a little theory is not without its practical value in seeking the reason for the effectiveness of the churn-drill. Much of the energy of the blow of a hammer is lost in the form of heat at the head of the drill. This loss does not occur with the churn-drill. It takes some skill to start a hole with a ball-drill and to keep it plumb; but the time spent in acquiring this skill is repaid many times over if quarry operations with hand drills are to be moderately extensive.

The effect of the size of the hole upon the speed of drilling appears never to have been carefully determined. One authority says that to double the diameter of the hole decreases the speed of drilling by one-half. Another authority thinks that doubling the diameter divides the speed by four. According to the first authority, if a man could drill 12 ft. of 1-in. hole in a shift, he could drill only 6 ft. of 2-in. hole in a shift. According to the second authority, only 3 ft. of 2-in. hole could be drilled per shift.

Cost of Hammer Drilling.—The diameter of the hole, the angle at which the hole is driven and the presence or absence of water in the hole, all affect the cost of drilling by hand. The method of drilling with hammer-drills or with churn-drills is also an important factor in the cost. Obviously the character of the rock is the most important factor; but unfortunately very few reliable records of cost of drilling in different kinds of rock are to be found. From some observations on hammer drilling with a 1½-in. starting bit I have found that where one man is holding the drill vertically and two men are striking, the rate of drilling a 6-ft. hole is as follows:

	Ft. in 10 hrs.	Cost per ft., cts.
Granite	7	76
Trap (basalt)	11	48
Limestone	16	33

The cost is based upon a wage rate of \$1.75 per 9-hr. day per man; and does not include the cost of sharpening drills, which may be taken at 5 to 8 cts. per ft. more.

I have found that a man drilling plug and feather holes in granite, each hole being ⅝-in. diam. by 2½ ins. deep, will average one hole in 5 mins., including the time of cleaning out holes, the driller striking about 200 blows in drilling the hole. No water is used in drilling these shallow holes, for the dust is readily and quickly cleaned out with a little wooden spoon. In 8 hrs. of steady work about 100 holes can be drilled, which is about 21 ft. of ⅝-in. hole. But in plug and feather work part of the time is spent in selecting rock, driving the plugs, etc., so that 50 or 60 holes drilled and plugged and feathered are generally counted a fair day's work.

I am indebted to Mr. John B. Hobson for the following data of hammer drilling in a British Columbia mine: Rock was augite diorite and firm red porphyry; starting bit, 1¾ ins.; finishing bit, 1¼ ins.; ⅝-in. steel; holes, 6 ft. deep; 8-lb. hammer. Two miners (one holding drill and one striking) averaged 14.8 ft. per 10-hr. shift. With wages at \$2 a day the cost was nearly 28 cts. per ft. of hole.

Mr. Frank Nicholson states that in mining chalcopryite in magnesian limestone at St. Genevieve, Mo., a day's work for a striker and a holder was 13 ft. of hole drilled. The drills had 1¼-in. starting bits, ⅝-in. octagon steel being used.

In excavating hard porphyry for the rock-fill dam at Otay, Cal., Mr. W. S. Russell states that a good day's work for three men drilling (one holding and two striking) was 6 to 8 ft. of hole, costing about 80 cts. per ft. of hole drilled. The holes were drilled 20 ft. deep vertically and sprung. This was an unusual depth of hole for hammer drilling, and accounts for the high cost per foot. It shows also how uneconomic is hammer drilling in deep vertical holes compared with churn drilling.

In driving a small (3 x 4½-ft.) tunnel through tough sandstone one driller averaged 4 to 5 holes, each 1½ ft. deep, per 8-hr. shift, using ⅝-in. bit for the starter; and, upon cleaning up, the advance

was 1 ft. per shift for one man. Each hole was charged with half a stick of 75% dynamite.

Cost of Hand Drilling in Granite.*—Mr. George C. McFarlane is authority for the following data on work done by him for Grand Trunk Pacific R. R., in Canada:

Steam drills were used in all the large cuts, while in the smaller cuts hand drills were used. With hand drills, holes as deep as 50 ft. were put down. Steel 1 in. in diameter was used to make the drills, which were gaged to 1 1/8 in. This size drill was used for the entire depth of the hole. The hand drillers worked 3 men in a gang. In starting the hole, and until it reached a depth of about 6 ft., 2 men did the striking and one man held the drill. In drilling holes to a greater depth all three men used striking hammer, the rebound and jumping of the drill turning it enough to keep the hole fairly round. The rocks encountered on this work are hard granite, traps and diabase of the Laurentian and Huronian system.

Hand drillers, when working by the day, were paid \$2.25 for 10 hrs., but, when paid per foot drilled, received 45 cts. This price per foot does not include sharpening or carrying steel to the shop. In drilling block holes, every hole less than 1 ft. in depth was counted as being a foot.

The following are some records of hand drilling:

One gang of three men, in drilling 10 to 14-ft. holes in dark hornblende, averaged 29 ft. per day.

In drilling red granite, 20 ft. is about the average per day.

In trap and diabase rock, 18 to 19 ft. is an average day's work.

In drilling block holes, a less number of feet is drilled per day. A record for six days for one gang on block-hole work was: Monday, 1 hole 36 ins. deep; 1 hole 45 ins. deep; 8 holes from 6 to 12 ins. deep; total driven, 11 ft. 7 in. Tuesday, 1 hole 22 ins.; 1 hole 18 ins.; 4 holes 6 to 9 ins.; total, 5 ft. 11 ins. Wednesday, 1 hole 36 ins.; 1 hole 22 ins.; 1 hole 17 ins.; 5 holes 6 to 12 ins.; total, 9 ft. 9 ins. On Thursday the drilling done was for holes to square up bottom of cut, there being 5 in all; 1 hole was 68 ins.; 1 hole 50 ins.; 1 hole 24 ins.; 1 hole 40 ins.; 1 hole 28 ins.; total, 17 ft. 6 ins. On Friday 11 holes from 6 to 16 ins. were driven. Saturday, 1 hole 44 ins.; 1 hole 30 ins.; and 7 holes from 6 to 9 ins.; total, 10 ft. 3 ins. This gives a total of 82 ft. 8 ins. in 49 holes, or an average depth of about 16 ins.

For sharpening the steel a blacksmith and a helper were employed, and a "nipper" to carry the steel back and forth from the cut and shop. For sharpening the steel for 5 gangs of drillers, who put down 2,142 ft. in a month, we have the following cost:

Blacksmith, 25 days at \$3.50.....	\$ 87.50
Helper, 24 days at \$2.00.....	48.00
Nipper, 24 days at \$2.00.....	48.00
12 sacks coal	12.00
	<hr/>
	\$195.50

*Engineering-Contracting, Nov. 27, 1907.

This means an average cost of sharpening per lin. ft. of hole drilled of about 9 cts.

This gives us a total cost of drilling and sharpening drills for the examples given as follows:

Dark hornblende (deep holes) 29 ft. drilled per day—	
Drilling, per ft.	\$0.23
Sharpening, per ft.	0.09
Total, per ft.	\$0.32
Red granite (deep holes), 20 ft. drilled per day—	
Drilling, per ft.	\$0.34
Sharpening, per ft.	0.09
Total, per ft.	\$0.43
Red granite (shallow block holes), 10 ft. 3 in. drilled per day—	
Drilling, per ft.	\$0.65
Sharpening, per ft.	0.09
Total, per ft.	\$0.74
Trap and diabase (deep holes), 18 to 19 ft. drilled per day—	
Drilling, per ft.	\$0.25
Sharpening, per ft.	0.09
Total, per ft.	\$0.44
Average of 5 gangs, 18 ft. drilled each day—	
Drilling, per ft.	\$0.37
Sharpening, per ft.	0.09
Total	\$0.46

This gives an average of 19 ft. at a cost of 47 cts. per lin. ft. for drilling and sharpening steel. This includes both deep and shallow holes.

Cost of Churn Drilling.—I am indebted to Mr. W. M. Douglass, of the firm of Douglass Bros., contractors, for the following data on drilling with churn-drills, for railroad work in western Ohio. Three drillers were used for putting down the first 18 ft. of hole in blue sandstone the first day (10 hrs.), and four men were used for putting down the last 12 ft. of hole, so that it required 70 hrs. of labor at 15 cts. per hr., or \$10.50, for a 30-ft. hole, making the cost 35 cts. per ft. In brown sandstone it required 70 to 80 hrs. labor to put down 30 ft. The drill holes were 2¼ ins. at top and 1½ ins. at bottom. Drilling with steam drills in this same stone, holes 20 ft. deep, cost 12 cts. per ft., including everything except interest, depreciation and drill sharpening. The cost of hand drilling agrees very closely with my own records of similar work in Pennsylvania.

Trautwine gives the following rates of drilling 3-ft. vertical holes, starting with a 1¼-in. bit, one man drilling with a churn-drill, shift 10 hrs. long:

Solid quartz	4 ft. in 10 hrs.
Tough hornblende	6 ft. in 10 hrs.
Granite or gneiss	7.5 ft. in 10 hrs.
Limestone	8.5 ft. in 10 hrs.
Sandstone	9.5 ft. in 10 hrs.

It should be observed that the holes in this case are shallow (3 ft.), and the diameter (1¼ ins.) is large for such shallow holes,

indicating that Trautwine's data applied to rock excavation where black powder was used.

Sizes of Air Drills.—The size of an air drill is denoted by the inner diameter of its air or steam cylinder; thus a $2\frac{1}{4}$ -in. air drill is one having a cylinder $2\frac{1}{4}$ ins. diam.

The smallest sizes, $2\frac{1}{4}$ -in. drill, is called a "baby drill," or a one-man drill—the latter name being given to the drill because it can readily be moved about and set up by one man. For narrow work in mines the baby drill is adapted. It is also used for drilling plug and feather holes, and might often be used profitably for shallow cuts and trenches. The most commonly used sizes for general contract work, tunnelling and mining are the $3\frac{1}{2}$ -in. and the $4\frac{1}{2}$ -in. drills. The drill is churned back and forth in the hole by compressed air or steam power, and after each stroke it is mechanically turned a fraction of a circle. The drill is fed forward by hand, a crank at the end of a feed-screw being used for this purpose. A longer drill is inserted every 2 ft. in depth of hole, for 3 ft. is the limit of feed of the ordinary feed-screw used.

Data as to Rock Drills.—Table VI gives approximately the principal data regarding air drills.

Test of Air Consumption at the Rose Deep Mine.—A 6-hour run at the Rose Deep Mine, South Africa, showed the following results for 31 drills: The compressed air averaged 70 lbs. per sq. in. and each $2\frac{1}{4}$ -in. drill consumed 81 cu. ft. of free air per minute, including all leakage of pipes (there was less leakage than is common in mines). Each drill required 43 lbs. of coal per hour, to supply this compressed air; and each 3.4 lbs. of coal developed 1 hp. per hr., by the indicator on the steam engine, evaporating 6.74 lbs. of water from 212° F. The average horsepower of the compressor engine was 12.7 I. H. P. per drill; but all the drillers were trying to make a record, and accomplished in 6 hrs. an amount of drilling that ordinarily took 8 hrs. The power plant was a vertical King-Reidier Compound Steam and Double Stage Compressor, with two boilers of the horizontal return tubular type.

Tables of Air Consumption in Catalogues.—Table VII is given in the catalogue of one of the well-known drill manufacturers, and is said to be based upon actual tests of single drills running continuously without stops for changing bits, etc.

TABLE VII.—CUBIC FEET OF FREE AIR PER MINUTE REQUIRED TO RUN A ONE-DRILL PLANT.

Gauge pressure.	Diameter of Drill Cylinder													
	2 in.	$2\frac{1}{4}$ in.	$2\frac{1}{2}$ in.	$2\frac{3}{4}$ in.	3 in.	$3\frac{1}{2}$ in.	$3\frac{3}{4}$ in.	$4\frac{1}{4}$ in.	$4\frac{1}{2}$ in.	$4\frac{3}{4}$ in.	5 in.	$5\frac{1}{4}$ in.	$5\frac{1}{2}$ in.	$5\frac{3}{4}$ in.

compressor the manufacturers advise multiplying the quantities given in Table VII by the factors given in Table VIII.

TABLE VIII.

Number of drills....	1	2	5	10	15	20	30	40	70
Multiply value in Table V, by.....	1	1.3	4.1	7.1	9.5	11.7	15.8	21.4	22.2

Tables similar to these are given by other manufacturers. In answer to letters of inquiry I have been informed that such tables are "based upon experience in a large number of mines."

The actual drilling time, that is, the time when the drill is actually striking blows, is seldom over 70%, and often not more than 40% of the length of the shift. Knowing the conditions of work, the reader will be able (with the aid of data given subsequently) to predict approximately the per cent. of actual drilling time. Then, if there are more than, say, 10 drills, he can multiply the air consumption of one drill (when actually drilling) by the percentage of drilling time in the shift, and the product will be the average air consumption of each drill. If there are less than about 10 drills it will not be safe to figure so closely, because the fewer the drills operated from one compressor, the more likely is it that all or nearly all of them will be using air at the same time. The larger the number of drills, on the other hand, the more certain it is that some will be changing bits while others are drilling, and thus draw a steady, average amount of air from the compressor.

Steam Consumption.—When steam is piped directly from the boiler into a drill, practically the same number of cubic feet of steam are consumed as of cubic feet of compressed air. We may assume that a cubic foot of steam will do practically the same work in a drill as a cubic foot of compressed air at the same pressure, because neither the steam nor the air acts to any great extent expansively in a drill cylinder, due to the late cut off. This being so, 0.21 lb. of steam is equivalent to 1 cu. ft. of free air, or 1 lb. of steam is equivalent to nearly 50 cu. ft. of free air, or 1 cu. ft. of free air is equivalent to 0.035 lbs. steam—all at the same pressure of 75 lbs. per sq. in. If a drill consumes at the rate of 100 cu. ft. of free air per min., it will consume 6,000 cu. ft. of free air in an hour. If it were using steam in its cylinder instead of air (at 75 lbs. pressure), it would, therefore, consume $6,000 \times 0.035 = 210$ lbs. of steam (at 75 lbs. pressure) in an hour.

When coal is burned under a boiler a large percentage of its heat passes up the chimney in the gases and is lost; and in addition to this loss the boiler itself radiates heat constantly. The greater part of the loss occurs in the heat that goes up the chimney. In large, well-designed boilers, properly protected by asbestos or similar covering, the coal burned will develop steam to about 80% of the full heat value of the fuel; the efficiency of the boiler and furnace is then 80%. In locomotive boilers, where forced draft is used, firing not of the best and boiler exposed to moving air, the efficiency

is often as low as 45%. The efficiency of a good boiler of moderate size (100 hp.), well housed, is ordinarily about 75%. A small (20 hp.) boiler exposed to the wind has an efficiency of about 60% when not forced. If a small boiler is used to run one drill, the boiler must always have up enough steam to keep the drill running at nearly full capacity; but when the drill is stopped, during the changing of bits, moving, etc., there is a waste of steam, because the period of stoppage is not long enough to permit the fireman to make any material change in the firing and in the draft.

When a $\frac{3}{4}$ -in. drill is operated by steam from a small boiler, about 600 lbs. of coal are ordinarily required per 10-hr. shift. But if a number of drills are supplied from a large, well lagged boiler, through steam pipes that are also lagged with asbestos covering, it is possible to cut down the coal consumption to 300 lbs. or less per drill per 10 hrs.

Gasoline Air Compressors.—Where not more than three or four drills are to be operated, probably no power can equal compressed air generated by gasoline. One pint of gasoline per hour per brake horsepower (B. HP.) of gasoline engine may be counted upon as the average consumption. It will require about 12 hp. to compress air for each drill ($3\frac{1}{4}$ -in. size); hence 12 pints, or $1\frac{1}{2}$ gals., of gasoline will be required per hour per drill while actually drilling. Since gasoline air compressors are self-regulating, when the drill is not using air very little gasoline is burned by the gasoline engine driving the compressor. If the drill is actually drilling two-thirds of the working shift, we may safely count upon using about 1 gal. of gasoline per hour of shift per drill, or 8 gals. per shift of 8 hrs. long. If gasoline is worth 15 cts. per gal., delivered at the engine, one drill consumes only \$1.20 worth of gasoline per shift of 8 hrs. A gasoline compressor possesses other very important economic advantages over a small steam-driven plant. First, there is the saving in wages of firemen; for, once started, a gasoline engine runs itself. Second, there is the saving in hauling or pumping of water and the hauling of fuel. Third, the cost of gasoline is often less than the cost of coal for operating a small plant.

Percentage of Lost Time in Drilling.—In operating machines of any kind the percentage of lost time is a factor that should receive the most careful consideration. The most serious loss of time in machine drilling is the time lost in changing bits and pumping out the hole; for, with a 2-ft. feed screw (which is the ordinary length), a new drill must be inserted for every 2 ft. of hole drilled. It takes from 4 to 16 minutes to drill 2 ft. of hole, counting the actual time that the drill is striking, and it ordinarily takes from 2 to 5 minutes to change bits and pump out the hole. I have often timed the work, however, where 9 minutes were spent in drilling, followed by 9 minutes lost by lazy drillers in changing bits. Counting no other time losses, then, half the available time was lost in the operation of changing bits. When shallow holes (4 ft. or less), are to be drilled, the drill steel is light, and there is often little

or no sludge pumping to be done. In such cases it is possible for the driller and his helper to change bits in 1 minute, or even less when they are rushing the work. So far as the changing of bits is concerned, men should be made to work with a vim. When men have to exercise their muscles incessantly for 8 or 10 hrs. there is reason in taking a slow, steady gait, but in machine work, muscular exercise is intermittent, and should be vigorous.

Next in importance to the time lost in changing bits is the time lost in shifting the machine from hole to hole. To move a tripod from one hole to the next and set up again ready to drill seldom consumes less than 7 minutes, even when the two men are working rapidly, when the distance to move is short, and when the rock floor is level and soft. When, however, the rock floor is irregular and hard, requiring the vigorous use of gad and pick, not only in making holes for the tripod leg points to rest in, but requiring, also, some little time in squaring up a face for the bit to strike upon, the two men may consume from 30 to 45 minutes, shifting the machine and setting up, if they work deliberately. In such cases it is advisable to have laborers working ahead of the drillers preparing the face of the rock, leveling the site of the hole, removing loose rock, etc. One can see clearly what a great saving in time may thereby be effected; yet, this simple expedient is seldom adopted; but the driller and his helper are usually left to themselves in preparing the ground for each new set up. Excluding the time required to change bits for the new hole, we may say that two men can ordinarily make a new set up with a tripod in 12 to 15 minutes, if they work rapidly.

Rule for Estimating Feet Drilled Per Shift.—We are now possessed of sufficient data to enable us to formulate a rule whereby the number of feet drilled per shift, under given conditions, may be predicted. I will not go into the method that I used in deducing the following rule, which is strictly correct, for the method is one of simple arithmetic. The rule is:

To find the number of feet of hole drilled per shift divide the total number of working minutes in the shift by the sum of the following quantities: The number of minutes of actual drilling required to drill one foot of hole, plus the average number of minutes required to change bits divided by the length of the feed screw in feet, plus the average number of minutes required to shift the machine from hole to hole divided by the depth of the hole in feet.

Suppose, for example, the shift is 10 hrs. long, that is, 600 mins.; that it requires 5 mins. to drill 1 ft. of the rock; that it requires 4 mins. to change bits and clean hole; that the feed screw is 3 ft. long; that the machine can be shifted from hole to hole in 16 mins.; and that each hole is 8 ft. deep. Then according to the rule we

have: The number of feet of hole per shift is $600 \div (5 + \frac{4}{3} + \frac{16}{8})$,
which is equivalent to $600 \div 9$, or 66⅔ ft. drilled per 10-hr. shift.

For those who can use simple algebraic formulas the above rule is much more compactly expressed in the following formula:

$$N = \frac{S}{r + \frac{m}{f} + \frac{s}{D}}$$

N = number of feet drilled per shift.

S = length of working time of shift in minutes = 600 for a 10-hr. shift when no time is lost by blasts, breakdowns, etc.

r = number of minutes of actual drilling required to drill 1 ft. of the rock.

m = number of minutes required to crank up, change drills, pump out hole and crank down.

m = 3 to 4 mins. ordinarily.

f = length of feed screw, in feet, ranging from 1½ ft. in "baby" drills to 2½ ft. in largest drills, but ordinarily 2 ft.

s = number of minutes required to shift machine from one hole to the next, including the time of chipping and starting the new hole, but not including the time of cranking up and cranking down. s ranges from 5 mins. for very rapid shifting on level rock, to 40 mins. for very slow shifting on irregular rock.

D = depth of hole in feet.

Even a casual study of the foregoing formula, or rule, must impress the practical man with the importance of the lost time elements in machine drilling; consequently of the value of timing the operation of changing bits and moving machines when the men do not know that they are being timed. Another feature that stands out strikingly is the reduced output of a drill working in a shallow hole. Let the reader solve a few problems, assuming first an average depth of hole of 16 ft. and finally an average depth of only 2 ft. (such as occurs often in the skimming work in road building), and he will never make the blunder of the contractor who bid the same price for rock excavation on the 2-ft. deepening of the Erie Canal as had been bid for the 16-ft. excavation on the Chicago Canal.

If we assume that the shift is 10 hrs. long; that the rate of drilling is 1 ft. in 5 mins.; that it takes 4 mins. to change bits and pump out the hole at each change of bits; that the feed screw is 2 ft. long; and that it takes 15 mins. to shift from one hole to the next; by applying the rule we obtain the following results:

Depth of hole, ft.	1	2	3	5	10	15	20
Feet drilled in 10 hrs.	27	41	50	60	70	75	80

When drillers are lazy they may readily consume 8 mins. in changing bits and pumping out the hole each time. With all conditions the same as before, excepting that 8 mins. are consumed in changing bits, we have the following results:

Depth of hole, ft.	1	2	3	5	10	15	20
Feet drilled in 10 hrs.	25	36	43	50	57	60	62

It will be seen that in deep hole drilling 20% decreased efficiency results from just a little laziness in changing bits, under the condi-

tions assumed; and in softer rocks the percentage of decreased efficiency is much greater. Where the holes are shallow the time involved in shifting from one hole to the next becomes an important factor. Assuming that the conditions are the same as in the first instance, except that 30 mins. are consumed in shifting from one hole to the next, then we have the following results:

Depth of hole, ft.....	1	2	3	5	10	15	30
Feet drilled in 10 hrs.....	16	27	35	46	60	67	70

Rates of Drilling in Different Rocks.—Unfortunately no published record exists showing rates of drilling in different kinds of rock with given air or steam pressures and given sizes of drill bits. Such scattering records as are to be found merely give the feet of hole drilled per shift. From data obtained by observation I have compiled the following table for drilling with $3\frac{1}{2}$ -in. machines using air or steam at 70 lbs. pressure, starting bit about $3\frac{1}{2}$ ins. and finishing bit about $1\frac{1}{2}$ ins.:

	Time to drill 1 ft.
Soft sandstones, limestones, etc.....	3 mins.
Medium, ditto	4 mins.
Hard granites, hard sandstones, etc.....	5 mins.
Very hard traps, granites, etc.....	6 to 8 mins.
Very soft shales, and other rocks that make sludge rapidly and when a water jet is not used.....	8 to 10 mins.

That the inexperienced reader may have a good general conception of what constitutes a day's work under ordinary conditions the following summary may be of benefit: In drilling vertical holes, with the drill on a tripod, the holes being from 10 to 20 ft. deep, shift 10 hrs. long, I have found that in the hard "granite" of the Adirondack Mountains, New York, 48 ft. is a fair 10-hr. day's work. In the granites of Maine and Massachusetts 45 to 50 ft. is a day's work. In New York City, where the rock is mica schist, deep holes are drilled at the rate of 60 to 70 ft. per 10-hr. shift by men willing to work, but 40 to 50 is nearer the average of union drillers. In the very hard trap rock of the Hudson River 40 ft. is considered a fair day's work. In the soft red sandstone of northern New Jersey 80 ft. are readily drilled per day wherever the rock is not so seamy as to cause lost time by the sticking of the bit; in fact, I have records showing 110 ft. per 10-hr. shift in this rock. In the hard limestone near Rochester my records show about 70 ft. per 10-hr. shift. In the limestone on the Chicago Drainage Canal 70 to 80 ft. was a 10-hr. day's work. In the hard syenite of Douglass Island, in open pit work, and where it is difficult to make set-ups, 36 ft. was the average per 10-hr. day. In the granites encountered in grading for the Grand Trunk Pacific R. R. in Canada, only 30 ft. were averaged per drill per day. In the limestone near Windmill Point, Ontario, $3\frac{1}{2}$ -in. drills average 75 ft. a day (holes 18 ft. deep); $2\frac{1}{2}$ -in. drills, 60 ft. a day, and "baby" drills, 37 ft. a day.

The foregoing examples all apply to comparatively deep vertical holes, in open excavation. In tunnel work there is no reason why a drill should not do about the same work per shift, were there no delays in timbering, mucking, waiting for gases to clear, etc. Such delays, however, often reduce the drill footage very much.

Cost of Sharpening Bits.—One blacksmith (with a helper) will sharpen about 140 bits a day, and under ordinary conditions will keep 5 to 7 drills supplied with sharp bits. On average rock a bit must be sharpened for every 2 ft. hole; in very soft rock a bit for every 4 ft., and in very hard rock a bit for every 1½ ft. of hole. On small jobs it is often necessary to have a blacksmith, even though there is only one drill at work. In such cases, however, the blacksmith should be kept busy with other work.

Cost of Drill Repairs.—Mr. Thomas Dennis, agent of the Adventure Consolidated Copper Co., Hancock, Mich., has kindly furnished the following data of the average monthly cost of keeping a drill in repair:

Supplies for repairs	\$ 1.21
Machinist labor	8.45
Blacksmith labor	1.60

Total repair charge per month.....\$11.36

The number of drills in the shop at any one time is about 15% of the total number. This low cost is based upon work where a large number of drills are used and well handled by the user.

I am indebted to Mr. Josiah Bond, mining engineer, for the statement that the cost of repairs averages 50 cts. per drill per shift in mines where a few drills are operated and renewal parts purchased from the manufacturers. In open cut work my experience is that 75 cts. per drill per shift is a fair allowance for renewals and repairs. In the gold mines of South Africa, where each drill works two shifts per day, the cost of drill repairs is \$300 per drill per year; while the first cost of a 3¼-in. drill with bar is \$185, according to a recent report of the Government Mine Inspector.

Mr. Josiah Bond, General Manager American Copper Mining Co., Somerville, N. J., wrote me as follows:

"As to the matter of drill repairs, I can give you only a few figures. In using drills for years, I find I have accurate figures for drill repairs for only three years. These place the repairs per drill at \$102.00, \$100.50 and \$93.76 per year. My opinion is that a drill used night and day for a year is sufficiently worn to make it good business to throw it away; though if a drill is used by only one man, and he is made responsible for its condition, I think the life of a drill is at least three years (one shift). Of course, studs and side rods will have to be replaced occasionally, and other small repairs must be made. A well-made heavy bar or column should outlast four drills, and arms are probably strong enough to kill three drills. And the drill itself is the weak part; as soon as the cylinder and piston are enough worn to make a day's work only 80 ft. instead of 120, or even 100 ft., it is clear that you are losing money by keeping it at work. I have always wanted two idle drills and one idle column and arm, etc., for five working drills. From my practice, which has been a pretty hard one, developing with low-priced labor, I should estimate a stopping drill to cost, including repairs and its own life, about 50 cts. per shift.

"Where an operation is large enough to warrant the erection of a

machine shop, sufficiently equipped to make all parts of drills, this cost can probably be cut in two; and in old mines, even without this, where the work is more regular, a saving can be made, because breakages do not occur so often. My practice has been without the luxury of a good shop, and all repairs are purchased, with the exception of a few of the simple parts, like side rods, etc.

"Much depends on the care given a drill, and the rock to be drilled makes a great difference also, but the above figures are, I should hope, outside prices; but in my work, drills have always been a secondary consideration."

The following table gives the cost of repairing 25 drills for 11 months in 1905, at the Wabana Iron Mines, Nova Scotia:*

Month of	Total repairs.	Amt. per drill per month.
January	\$ 68.22	\$2.86
February	85.53	3.576
March	165.10	6.007
April	33.92	1.21
May	46.98	1.86
June	49.41	1.98
July	110.89	4.49
August	316.81	13.50
September	140.62	5.20
October	259.60	10.66
November	204.75	7.80
Total and av.	\$1,481.93	\$5.40

In addition to this add \$1.75 per day for labor or 7 cts. per drill per day, or \$3 per month, making a total of \$7.40 per drill per month.

The average cost of repairs was \$5.40 per month per drill (drills worked one shift only each day), not including the cost of labor of repairing. It takes all of one man's time, at \$1.75 per day, keeping the drills in repair, or practically \$2.00 per month per drill. The parts used in making repairs are all bought of the manufacturers. We see that the total cost of drill repairs has been about \$7.40 per drill per month, or 30 cts. per drill per 10-hr. day, which is a very moderate cost, and speaks well not only for the make of the drills, but for the care given to them.

Cost of Operating Drills.—When operating a single (3¼-in.) drill supplied by steam from a small portable boiler, I find the cost is usually as follows for a 10-hr. shift:

1 drill runner	\$ 3.00
1 drill helper	1.75
1 fireman	2.00
650 lbs. of coal (0.3 ton at \$3)90
Water, if hauled, say75
Hauling and sharpening 30 bits (incl. new steel) at 4 cts. ..	1.20
Repairs to drill and hose renewals75

Total per 10 hrs. \$10.85

The foregoing is merely an example, based, however, upon several different jobs; but in each case the accessibility of a blacksmith, the nearness to water, the price of coal delivered at the

*See *Engineering-Contracting*, February 1, 1906, p. 42.

boiler, etc., must be determined before an accurate estimate can be made. If 4 drills, for example, are to be operated from the same boiler, the fuel bill will be somewhat reduced even if the pipes are not covered with asbestos, and of course the wages of the fireman will be distributed over 4 drills. It will then pay to have a blacksmith at hand. If 10 or more drills are run by steam from a central boiler, and if the main pipes are lagged, the fuel should not much exceed 300 lbs. per drill per 10-hr. shift. By the rules previously given a fairly close estimate can be made of the number of feet of hole that each drill should average. If 60 ft., for example, are to be a fair day's work in limestone or sandstone, we have $\$10.25 \div 60 = 17$ cts. per ft. as the cost, exclusive of superintendence, plant installation and plant rental.

If a central compressor or steam plant supplies power for, say, 15 drills, we may estimate the cost of operating each drill as follows:

1 drill runner	\$3.00
1 drill helper ..	1.75
1-15 fireman at \$2.2516
1-15 compressor man at \$3.....	.20
300 lbs. coal (water nominal) at \$3 ton.....	.45
Sharpening bits, 30 at 3 cts.....	.90
Repairs to drill, hose, etc.....	.75

Total for 60 ft. of hole at 12 cts.....\$7.20

If the cost of each drill and 1/15 part of the compressor plant is \$350, and 30% of this is assumed as a fair allowance for annual plant rental, we have \$105 to charge up against each drill for "rental," or about 60 cts. per shift if 200 shifts are worked each year, or about 1 ct. per ft. of hole drilled.

In my book "Rock Excavation—Methods and Cost" will be found detailed data on the cost of drilling blast-holes with well-drillers of the "Cyclone" type. The holes were 3 ins. diam. \times 34 ft. deep in sandstone and cost $12\frac{1}{2}$ cts. per ft. to drill. Other data on drilling with well drillers will be found in this handbook, page 253.

Piece Rate and Bonus System in Drilling.—The original "hole contract system" was a piece rate system, whereby the driller was paid for his work according to the number of lineal feet of hole drilled. I have modified the original system by paying the drillers a daily wage plus a bonus for each lineal foot in excess of a stipulated minimum. See Section I of this book.

Cost of Loading by Hand.—Where a laborer has merely to pick up and cast one-man stone into a jaw crusher, I have had men average 34 cu. yds. of loose stone handled per man per 10-hr. shift, which is equivalent to about 20 cu. yds. of solid rock. This, I believe, marks the maximum that may be done, day in and day out, by a good worker, where the stone has scarcely to be lifted off the floor to toss it into the jaws. Every stone, however, was handled and not shoved or slid into the crusher.

On the Chicago Canal the average output per man per 10-hr. shift was about 7 cu. yds. loaded into dump cars, and this included some sledging. The average per man loading into the low skips used on the cableways, involving very little sledging, was about

10 cu. yds. of solid rock per man per 10-hr. shift. The best day's record was 18.6 cu. yds. per man loading into skips. In loading cars about 5 men out of the force of 16 loaders were kept busy sledging the rock; but with the cableways not only was it easier to roll large rocks into the skips (or "scale pans"), but very large rocks were lifted with grab hooks and chains and carried to the dump without sledging.

In loading wagons with stone readily lifted by one man, the wagon having high sides, I have found that a man will readily average 10 cu. yds. solid, which is equivalent to 17 cu. yds. loose measure per day of 10 hrs. The same man will throw the stone out of the wagon twice as fast as he will load it, and this does not mean dumping the wagon, but handling each stone separately. In loading a wagon having a stone-rack, and no sides, two men, passing stone up to the driver, who cords the stone on the rack, will load 1 cu. yd. solid stone in 13 mins. when working rapidly, but this is too high an average to be maintained steadily for a full day. A driver will unload 1 cu. yd. solid (or 1.7 cu. yd. loose) from such a stone-rack, by rolling the stone off, in 7 mins. if he hurries, but he may take 20 mins. if he loafs. A man will readily load a wheelbarrow with stone already sledged and ready for the crusher at the rate of 13 cu. yds. solid (or 21 cu. yds. loose) in 10 hrs.

Cost of Handling Crushed Stone.—In handling stone after it has been crushed to 2½-in. size, or smaller, a shovel is used, and the output of a man depends very largely upon whether he is shoveling stone that lies upon smooth boards or upon the ground. I have often had 6 good shovelers unload a canal boat holding 120 cu. yds. loose measure of crushed trap rock (2-in. size) in 9 hrs., but after breaking through to the floor the shoveling was comparatively easy; this is 20 cu. yds. loose (or 12 cu. yds. solid) per man per day shoveled into skips. In shoveling from flat cars into wagons the same rate can be attained, but in shoveling from a hopper-bottom car, where there is at no time a smooth floor along which to force the shovel, an output of 14 cu. yds. loose measure (or 8 cu. yds. solid) is a fair 10-hr. day's work. In shoveling broken stone off the ground into wagons it is not safe to count upon much more than 12 cu. yds. loose measure (or 7 cu. yds. solid) per man per 10 hrs. A careful manager will, if possible, provide a smooth platform, preferably faced with sheet iron, upon which to dump any stone that is to be re-handled by shovelers. Small stone, ¾ in. or less in diameter, is easily penetrated by a shovel and need not be dumped upon a platform. A clamshell bucket operated by a locomotive crane, or derrick, is doubtless the most economic method of loading broken stone from cars or stock piles, where the quantity to be handled warrants the installation.

Cost of Unloading Broken Stone With a Clamshell Bucket.*—A

**Engineering-Contracting*, Oct. 2, 1906.

novel expedient for increasing the power of a derrick was practiced recently in an extensive piece of concrete work involving the unloading of broken stone from vessels into wagons. The work in question was retaining wall work on track improvements on the New York Central & Hudson River R. R., at Ossining, N. Y. Scows brought broken stone to an adjacent wharf and the plan was to unload the stone into wagons, using a stiff leg derrick equipped with a clamshell bucket. The derrick at hand was an ordinary affair, with 10 x 10-in. mast, 8 x 8-in. stiff legs, and a 40-ft. boom, operated by a 5 x 10-in. National double drum hoisting engine, capable of handling a 3,000-lb. load with the ordinary single line rigging. As the clamshell weighed 2,500 lbs. empty and fully 4,700 lbs. when loaded with broken stone, some expedient was necessary to carry out the plan. The problem was finally worked out as follows:

The bucket was suspended from the boom by a chain of just sufficient length to allow it to open and close. The end of the hoisting line was also fastened to the end of the boom and run over a single block attached to the closing wheel on the bucket, then through the sheave of the boom and thence to the engine drum, making a double line which gave the engine sufficient power. The loss of speed resulting was of little moment. The stone was unloaded directly into wagons so that the hoisting distance was very small, and the time consumed in swinging was greater than the time necessary to hoist. The result was that there was practically no reduction of speed of operation. The hoisting was done, of course, by raising and lowering the boom, using the second drum of the engine.

The derrick was operated by an engineman and a helper and handled regularly 100 cu. yds. per day. In addition to the derrick work there were 24 hrs. labor on a 500 cu. yd. boat load cleaning out the stone that could not be reached by the bucket. The labor cost of unloading vessels into wagons, using the apparatus described, can then be itemized as follows:

One engineman, at \$2.50.....	2.5 cts. per cu. yd.
One helper, at \$1.50.....	1.5 cts. per cu. yd.
Labor, cleaning	0.7 ct. per cu. yd.

Total labor cost.....4.7 cts. per cu. yd.

Cost of fuel would not add more than 1½ ct. per cu. yd., making a total of about 5¼ cts., to which should be added cost of erecting and removing the plant, and plant maintenance.

The total cost of the derrick fitted as described was \$1,500. The work in connection with which the derrick was used is being done by Ford & Waldo, Engineers and Contractors, Park Row Building, New York, N. Y., and the double line rigging was devised by them.

Unloading Scows With a Clamshell.—In building the masonry anchorage for the Manhattan Bridge, Mr. Gustav Kaufman used a 1½ cu. yd. Hayward clamshell bucket operated by a 50-hp. electric motor, and unloaded 600 cu. yds. of broken stone per day from scows. In addition to the operator of the clamshell bucket, about 8 men

were kept busy trimming up the stone in the scow not handled by the bucket. The clamshell bucket dumped into a 10 cu. yd. hopper provided with a shaking chute which fed the stone onto a Robins belt conveyor. Careful timing showed that the bucket made $1\frac{1}{9}$ scoops per minute, averaging 0.9 cu. yd. per scoop. Tests showed that it required 20 hp. while loading, 42 hp. while lifting, 42 hp. while swinging loaded, and 20 hp. while swinging back empty. But if we assume a constant average expenditure of 30 hp., we have about 24 kw., or 240 kw. hrs. per day. Based upon these data we would have the following approximate cost:

	Per day.	Per cu. yd. Cts.
1 operator	\$ 3.00	\$0.5
240 K. W. hrs. electricity at 4 cts.....	9.60	1.6
8 laborers at \$1.75.....	14.00	2.4
Total	\$26.60	4.5

Another $\frac{1}{2}$ ct. per cu. yd. would cover the plant interest and maintenance.

Cost of Handling Broken Stone With a Derrick.—Where crushed stone must be handled with a derrick, as in unloading boats, I have found the following to be about the best that can be done per day:

	Per day.
6 shovelers, at \$1.50.....	\$ 9.00
1 hooker on	1.50
2 tagmen (swinging the boom).....	2.00
1 dumpman	1.50
1 water boy	1.00
1 team on derrick	3.50
1 foreman	3.00

120 cu. yds. (loose) at 19 cts. =\$22.50

It commonly costs about 25 cts. per cu. yd. (loose measure) to unload a boat of broken stone using skips holding 18 cu. ft. each, and a team on the derrick for raising them. Where any great amount of such work is to be done, however, a hoisting engine and a derrick provided with a bull-wheel should be used. The following shows the cost of unloading flat cars containing broken stone (2-in. size), using a derrick with a bull-wheel for "slewing" the boom:

5 shovelers, at \$1.50	\$ 7.50
1 dumpman	1.50
1 engineman	2.50
$\frac{1}{2}$ ton coal at \$2.....	1.50

100 cu. yds. (loose) at 13 cts. =\$13.00

In this case a stiff-leg derrick, 40-ft. boom, with a bull-wheel, operated by a double cylinder (7x10) engine, handled self-righting steel buckets holding 20 cu. ft. each. Water for the engine was delivered in a pipe. The engineman was the foreman.

In neither of the two cases just cited is the cost of installing the derrick included, nor is the interest and depreciation of plant included. It takes 6 men and a foreman one day to dismantle and move a stiff-leg derrick a short distance (100 or 200 ft.), and one

more day to set it up again, or \$26 for the two days' work. This includes moving the engine and the stones used to hold the stiff legs down; and it applies to a slow gang of workmen.

A guy derrick with a 50 or 60-ft. boom swung by a bull-wheel and a hoisting engine will often prove the cheapest device for loading cars with blasted rock. If the derrick is handling skips loaded with stone, the following is a fair average of the time elements in handling each skip load:

Changing from empty to loaded skip	35 secs.
Swinging (half circle)	20 secs.
Dumping skip	15 secs.
Swing back	20 secs.
Total	90 secs.

If there were no delays, it would be possible to handle 400 skip loads in 10 hrs. Usually, however, the loaders will cause more or less delay, so that it is safer to count upon what they will average rather than upon what the derrick can do. One derrick cannot serve a very long face, and the number of men that can be worked to advantage in a given space is always limited; hence I repeat that with a good derrick provided with a bull-wheel the derrick can ordinarily handle more stone than can be delivered to it by the men. The economic size of the skip load is entirely dependent upon the size of the hoisting engine, but a common size skip measures 5 x 6 ft. x 14 in. deep. Where much work is to be done a contractor should never try to get along with a derrick not provided with a bull-wheel for "slewing" the boom, for the wages of two tag-men would soon pay for a new outfit.

Cost of Loading Blasted Rock With Steam Shovels.—A contractor who has never had experience in handling hard rock with steam shovels is almost certain to overestimate the probable output of a shovel loading rock. This is due very largely to the common tendency to think of all rock as being a material that differs only to moderate degree in hardness. On the Chicago Drainage Canal, two 55-ton shovels, each working two 10-hr. shifts a day for four months, averaged 296 cu. yds. per shovel per shift of solid rock (limestone) loaded into cars, although it is stated that one day one of the shovels loaded 600 cu. yds. of rock in 10 hrs. The limestone on the Chicago Canal did not break up into small pieces upon blasting (a condition that is essential to economic steam shovel work in rock), but it came out in large chunks, much of which had to be lifted with chains, instead of being scooped up by the dipper. When each separate rock must be "chained out" in this way, a steam shovel is really no better than a derrick, and is, in fact, not so good.

On a large contract near New York City, where the rock is a tough mica schist that breaks out in large chunks even with close spacing of holes, a 45-ton shovel with a 2½-cu. yd. dipper averaged for several weeks about 280 cu. yds. of solid rock loaded in cars. Part of this rock was loaded with the dipper and part was chained.

On the Jerome Park Reservoir excavation in New York City the

rock is also a tough mica schist that blasts out in slabs even with heavy blasting. I am informed by Mr. R. C. Hunt, manager for Mr. John B. McDonald, contractor, that their 70-ton shovels loaded only 200 cu. yds. of solid rock per 10-hr. shift. Mr. Hunt says:

"This was in the gneiss rock (mica schist) of this vicinity. The fibrous nature of Manhattan and adjacent rocks causes it to break in such large and awkward shapes that the shovel cannot do itself justice. I therefore abandoned the use of shovels in the rock cuts and find that I can handle the rock with derricks more economically."

In thorough cut work on the Wabash Railroad, one 42-ton shovel loaded 240 cu. yds. of sandstone (solid measure) into dump cars in 10 hrs., as an average of a year's work; but about 10% of the working time was lost in breakdowns, etc.

In shale, or any friable rock that breaks up into pieces which readily enter the dipper, the output of a steam shovel is far greater than in hard rock such as we have been citing. Through the kindness of Mr. George Nauman, assistant engineer, Pennsylvania Railroad, I am able to give the output of several shovels working more than a year, in shale near Enola, Pa. Each shovel worked two 10-hr. shifts per day, six days in the week. In cut No. 1 there were nearly 2,000,000 cu. yds. of which 85% was rock. Of this rock a little was very hard limestone, some was blue shale nearly as hard, and most of it was red shale, somewhat softer. Excluding the first two months, the average output of each shovel per month of double-shift work was nearly 31,000 cu. yds., equivalent to 15,500 cu. yds. single-shift work. There were, on an average, four shovels at work, averaging 60 tons weight per shovel. The best month's output was 47,800 cu. yds. per shovel in August, 1903, and the poorest month (after work was well started) was 20,800 cu. yds. per shovel in February, 1904, working double shifts.

For costs of operating a steam shovel see the section on Earth Excavation.

Cost of Handling in Carts and Wagons.—Since a cubic yard of loose broken stone weighs about as much as a cubic yard of earth measured in place; and since, ordinarily, 1 cu. yd. of solid rock becomes 1.7 cu. yds. when broken, we may say that a team will haul about 60% as many cubic yards of solid rock per day as of earth. In other words, if the roads are such that 1 cu. yd. of packed (not loose) earth would make a fair wagon load for two horses, then 0.6 cu. yd. of solid rock would be a fair load. On page 121 the sizes of loads of earth that teams can haul are discussed, and it is only necessary to multiply the earth load as given there by 6/10 (or 60%) to find the equivalent load of solid rock.

Open-Cut Excavation.—This includes all rock excavation in open cuts (except trenches), where no special care is used to quarry the stone in certain sizes for masonry, but where explosives are used freely to break out the rock in sizes that can be handled with the appliances available.

Spacing Holes in Open-Cut Excavation.—A common rule is to

place the row of vertical drill holes a distance back from the face equal to the depth of the drill hole, and to place the drill holes a distance apart in the row equal to their depth. Another rule is to place the row of holes back from the face a distance equal to three-fourths their depth, and the same distance apart in the row. In stratified rock of medium hardness these rules may be followed in making the first experiments, but they will lead to serious error if applied to dense granitic rocks. In the limestone on the Chicago Canal, not much of which was loaded with steam shovels, the holes were usually 12 ft. deep and placed in rows about 8 ft. back of the face and 8 ft. apart. These holes were charged with 40% dynamite. In a railway cut through sandstone the holes were 20 ft. deep, 18 ft. back from the face and 14 ft. apart in the row. These holes were "sprung" three times, and each hole charged with 200 lbs. of black powder. In granite quarried for rubble for dam work, I have had to place the holes $4\frac{1}{2}$ to 5 ft. back of the face and the same distance apart, the holes being 12 ft. deep, about 2 lbs. of 60% dynamite being charged in each hole. On railway work in the Rocky Mountains about the same spacing was found necessary in granitic rock that was to be broken up into chunks that a steam shovel could handle. In pit mining at the Treadwell Mine, Alaska, the holes are drilled 12 ft. deep, in rows $2\frac{1}{2}$ ft. apart, the holes being 6 ft. apart in each row and staggered. This requires drilling 1.7 ft. of hole per cu. yd.

It is obviously impossible to lay down any hard and fast rule for the spacing of drill holes. In stratified rock that is friable, and in traps that are full of natural joints and seams, it is often possible to space the holes a distance apart somewhat greater than their depth, and still break the rock to comparatively small sizes upon blasting. In tough granite, gneiss, syenite and in trap where joints are few and far between, the holes may have to be spaced 3 to 8 ft. apart, regardless of their depth, for with wider spacing the blocks of stone thrown down by blasting will be too large to handle with ordinary appliances. The mica schist, or gneiss, of Manhattan Island is a good example of rock that requires close spacing of holes regardless of depth. I have seen holes in it 20 ft. deep and only 4 ft. apart.

The effect of spacing of holes upon the cost of excavation is best shown by tabulation of the feet of hole drilled per cubic yard excavated, as shown below:

Distance apart of holes, ft.	1	1.5	2	2.5	3	3.5	4	4.5	5
Cu. yds. per ft. of hole	.04	.08	.16	.23	.33	.45	.59	.75	.93
Ft. of hole per cu. yd.	27.0	12.0	6.3	4.3	3.0	2.2	1.7	1.33	1.08

Distance apart of holes, ft.	6	7	8	9	10	12	14	16	18
Cu. yds. per ft. of hole	1.33	1.80	2.37	3.00	3.70	5.32	7.25	9.52	12.06
Ft. of hole per cu. yd.	.75	.56	.42	.33	.27	.19	.14	.11	.08

Since in shallow excavations the holes can seldom be much further apart than 1 to $1\frac{1}{2}$ times their depth, we see that the cost of drilling per cubic yard increases very rapidly the shallower the excavation. Thus an excavation 3 ft. deep, with holes 2 ft. apart, requires 4.5 ft. of drill hole per cubic yard, as against 0.42 ft. of hole per cu. yd. in a deeper excavation where drill holes are 8 ft. apart. Failure to consider this fact ruined one contractor on the Erie Canal deepening, where rock excavation was only 3 ft. deep. Furthermore, the cost of drilling a foot of hole is much increased where frequent shifting of the drill tripod is necessary.

By observing carefully the appearance of rocks in different localities it is possible in a short time to become tolerably proficient in the art of estimating the probable distance apart that holes must be drilled for the best effect with given charges of given kind of explosive; and with this end in view a young man should avail himself of every opportunity of studying prevailing practice in spacing drill holes in different localities.

Cost of Excavating Sandstone and Shale.—In excavating shales and sandstones of the coal measures of Pennsylvania, Ohio, Virginia, etc., I find that holes are usually 20 to 24 ft. deep, and spaced 12 to 18 ft. apart. On an average we may say that for every cubic yard of solid rock there is 0.1 lin. ft. of drill hole, when cuts are very wide, covering large areas of ground; but in thorough cuts for railroads it is not safe to count upon much less than 0.2 ft. of drill hole per cu. yd. The holes are almost invariably "sprung" with 40% dynamite to create chambers at the bottom of the holes, and then charged with black powder. As low as $1/60$ lb. of dynamite per cu. yd. may be used for springing holes in shale, and as high as $\frac{1}{2}$ lb. per cu. yd. in sandstone that is to be very heavily loaded. I should put the average at $1/20$ lb. of dynamite per cu. yd. of shale, and $1/10$ lb. per cu. yd. of sandstone. In granite $\frac{1}{2}$ lb. per cu. yd. is common. A very common charge is 3 kegs (200 lbs.) of black powder per hole, or about 1 lb. per cu. yd. in side cuts, and $1\frac{1}{2}$ to 2 lbs. per cu. yd. in thorough cuts, although as high as 3 lbs. per cu. yd. have been used in thorough cuts in sandstone where special effort was made to break up the rock to small sizes for steam shovel work. The drilling of the deep holes costs not far from 40 cts. per lin. ft. where drilling is done by hand with wages at 15 cts. an hour, and it may be as low as 12 cts. a lin. ft. if well drillers are used. Soda powder costs about 5 cts. per lb., and 40% dynamite 12 cts. per lb. We have, therefore, the following:

	Cts. per cu. yd.
Drilling $1/10$ ft. to $2/10$ ft. at 40 cts.	4.0 to 8.0
Dynamite $1/20$ lb. to $1/10$ lb.	0.6 to 1.2
Powder, 1 lb. to 2 lbs.	5.0 to 10.0
Total for loosening the rock.	9.6 to 19.2

The rock is commonly loaded with steam shovels, and it is not safe to count upon more than 500 cu. yds. of shale, or 250 cu. yds. of sandstone per shovel per 10-hr. shift.

Summary of Open Cut Data.—The two cost items that the inexperienced man should seek first to inform himself upon, are: (1) The number of feet of hole drilled per cubic yard in different kinds of rock; and (2) the number of pounds of explosive required per cu. yd. under varying conditions. Below I have given a summary of these items as applying to open cut work discussed in this book; the table does not apply to trenching, tunneling or other narrow work. Two examples are given for sandstones and two for shales, such as occur in the coal measures of Pennsylvania. In a thorough cut on railroad work, we have conditions that approach trench work, requiring more feet of hole and more powder than in open side cuts; hence the difference between Examples 5 and 6, 7 and 8. It will be observed that the large amount of drilling in Example 3 is due to the shallowness of the face or lift, and in Examples 9 to 13 it is due to the toughness of the rock.

I shall greatly appreciate further contributions of similar data from my readers, for use in future editions. The greater the number of records, such as those in this table, the better will readers be able to judge the range and the average for each class of rock.

Example.	Per Cubic Yard.				Kind of Rock.
	Depth of Lift. Feet.	Feet of Hole.	Lbs. of Black Powder.	Lbs. of Dynamite.	
1.....	12	.4075	40% Limestone, Chicago Canal.
2.....	6	1.007	40% Limestone, for crushing.
3.....	2037	50% Limestone, for cement.
4.....	15	.4326	50% Limestone (holes sprung).
5.....	20	.10	1.0	.1	40% Sandstone, side cut.
6.....	20	.20	2.0	.2	40% Sandstone, thorough cut.
7.....	24	.08	.2	.02	40% Shale, soft, side cut.
8.....	24	.20	1.5	.10	40% Shale, hard, thorough cut.
9.....	16	1.3630	50% Granite, for rubble.
10.....	12	1.3380	40% Gneiss, New York City.
11.....	14	.6350	40% Gneiss, New York City.
12.....	12	1.7067	40% Syenite, Treadwell mine.
13.....	12½	.2244	52% Magnetic iron ore.
14.....	14	.3530	75% Trap, seamy.
15.....	16	1.0070	40% Trap, massive.
16.....	25	.1080	50% Granite, Grand Trunk Pacific (holes sprung, half the dynamite being used in springing).

By applying the preceding data as to unit costs of drilling, blasting, loading and hauling, it will be seen that rock excavation in open cuts ranges from about \$0.50 to \$1.50 per cu. yd., the lower price being for shales and sandstones and the higher price for cer-

tain granites and traps where holes are close spaced. It is a very common assumption that rock can be profitably excavated in open cuts at a contract price of \$1 per cu. yd., but it will be seen that each case requires special study.

Cost of Excavating Gneiss, New York City.—I am indebted to Mr. John J. Hopper, civil engineer and contractor, for the following data. The work involved the excavation of 29,295 cu. yds. of gneiss (or mica schist) at One Hundred and Twenty-seventh street, New York City. The drilling of the main holes was done with four 3½-in. Inger oil steam drills, and two "baby drills" were used for drilling block holes. The average height of the lifts was 12 to 15 ft., and the cut ranged from 2 to 63 ft. deep. Hand drillers and sledgers received \$2 per 10-hr. day; laborers handling stone and loading wagons received \$1.60; one of the machine drillers received \$3, and the rest of the drillers received \$2.75 a day. The baby drills were used only on the largest pieces thrown down by the blast; the ordinary sized stone from the blast was broken up by hand-drilled holes and by sledges to sizes suitable for building rubble foundation walls. A good deal of the stone was piled up during the winter until it could be sold. The drilling part of the plant cost \$1,800; the boilers, derricks, hoists, etc., cost \$1,080; 40% dynamite, costing 20 cts. per lb., was used. There were 18,433 lin. ft. of main holes drilled (not including block holes) in excavating 29,295 cu. yds. of solid rock. The total cost of the work, including the plant, cartage, sledging, etc., was \$52,635. The itemized cost was as follows:

	Cts. per cu. yd.
Foremen and timekeepers	8.0
Engineers and drillers	10.9
Sledgers	25.3
Derrickmen and helpers	9.6
Labor, loading, etc.	24.7
Hand drillers	11.7
Blacksmith and helper	5.3
Hauling away in wagons ...	40.6
Explosives	9.8
Coal, coke, oil, etc.	6.0
Repairs to drills	1.0
Repairs to boilers, derricks, etc.	1.2
Total per cu. yd.	\$1.67

Mr. Hopper informs me that in sound rock where 20-ft. holes could be drilled, a drill would average 70 ft. in 10 hrs.; but in shallow drilling the drills would frequently not average over 25 ft. each.

This is about as high a cost as need occur in open cut rock work of any kind, when wages are as above given.

See the section on Railways for cost of excavating gneiss for the New York Subway.

Cost of Gneiss Excavation for Dams.—Mr. J. Waldo Smith is authority for the statement that on several dam jobs done under his direction, near New York City, it had cost the contractors \$1.65

per cu. yd. to excavate gneiss in open cuts, when wages of common laborers were \$1.65 cts. per 10-hr. day. At Catona it had cost the contractors \$3.50 per cu. yd. to excavate gneiss in the foundation for the dam, where no blasting was allowed. At Boontown, N. J., under similar conditions, it had cost \$3.30 per cu. yd.

Summary of Costs on Chicago Canal.—The summary in Table X has been compiled by Mr. W. G. Potter. Common laborers in all cases receiving \$1.50 for 10 hrs. work, all delays of 1 hr. or more being docked. Wages paid the other classes of men are given in my "Rock Excavation." The tabulated costs do not include shop repairs, but do include field repairs. The drilling item appears not to include the cost of drill sharpening. Plant interest and depreciation are not included either—a very important item where such expensive machines are used. Explosives include caps and dynamite, 12 cts. per lb. for the 40% dynamite being assumed to cover the cost of explosives. General expenses include superintendence, watchmen and incidentals.

TABLE X.—COST IN CENTS PER CU. YD. (SOLID).

	Channeling.	Drilling.	Explosives.	General Ex- pense.	Pumping.	Conveying.	Pit Force.	Dump Force.	Total.
Brown Cantilever	3.9	4.1	3.0	3.2	1.0	3.6	14.6	0.0	33.3
Lidgerwood Cableway...	3.7	3.3	3.4	2.7	1.0	3.6	15.6	0.0	33.3
Hullett-McMyler Der- rick	3.9	4.0	7.4	2.5	1.3	5.3	18.3	0.0	43.2
Hullett Conveyor.....	4.1	3.7	3.5	3.3	1.2	6.2	21.4	0.0	48.9
Car Hoist No. 1.....	3.7	3.9	3.1	2.7	0.8	3.1	24.8	5.1	52.1
Car Hoist No. 2.....	3.9	3.6	3.9	3.2	0.9	1.2	22.9	2.3	47.1
Car Hoist No. 3.....	4.0	5.0	10.7	3.1	1.2	1.2	26.4	4.8	56.5

The descriptions of each of the foregoing machines and methods of excavating and transporting the rock (limestone) are given in my book on "Rock Excavation." The detailed cost of channeling per square foot is also given there.

Trenching in Rock.—This is a subject upon which practically nothing has ever been written. In consequence there is probably no class of rock work that is so often mismanaged; and, as a further consequence of the prevailing ignorance [engineers'] estimates of cost are often far too low and occasionally [as] far too high. In city specifications for sewer trenching in rock it is customary to pay the contractor only for rock excavated within specified "neat lines." If he excavates beyond the "neat lines" he does so at his own expense. In sewer work the most common practice is to specify that payment will be made for a trench 12 ins. wider than the outside diameter of the sewer pipe, and 6 ins. deeper than the bottom of the pipe when the pipe is laid to grade. The most rational specification that I have seen for general use in rock trenching is as follows: "All trenches in rock excavation will be esti-

rated 2 ft. wider than the external diameter of the pipe and 6 ins. below the sewer grade."

Different rocks vary greatly in the way the sides and bottom shear off upon blasting. The sides of trenches in soft rocks can be cut off clean when the blast holes are properly loaded; but tough granites, traps, etc., leave jagged walls, generally involving excavation beyond the "neat lines" specified.

In excavating thin bedded, horizontally stratified rocks the drill holes seldom need to go much, if any, below the neat lines; that is, 6 ins. below the bottom of the pipe. But in excavating thick bedded and tough limestones and the like, it is generally necessary to drill 12 ins. below the bottom of the pipe. In tough granites, traps, etc., it is often necessary to drill at least 18 ins. below grade in order to leave no knobs or projections after blasting that would require breaking off with bull points and sledges. Obviously the shallower the trench the greater is the importance of making due allowance for this extra drilling.

The common practice in placing drill holes is to put down holes in pairs, one hole on each side of the proposed trench; and, if the trench is wide, one or more holes are drilled between these two side holes. However, it is not always necessary to drill the two holes (one on each side); but in narrow trench work, such as for a 12-in. water pipe, one hole in the middle of the trench will usually prove sufficient if it is made of large enough diameter to hold a heavy charge of dynamite. For example, in trenching for a 12-in. water pipe in New Jersey trap rock, holes were drilled in the center of the trench, 6 ft. deep, and 2 ft. apart. The result was a great saving in the cost of drilling per cubic yard.

Cost of Drilling and Blasting in Trenches.—Next to tunneling there is no class of rock excavation requiring so much drilling per cubic yard as does trench excavation. In granites, if shallow holes are drilled by hand, the holes are frequently spaced not more than $1\frac{1}{2}$ ft. apart. If in a very narrow trench $1\frac{1}{2}$ ft. wide two holes are drilled in a row, one on each side of the trench, and if the rows are $1\frac{1}{2}$ ft. apart, we have two holes drilled in a square $1\frac{1}{2}$ ft. on a side; that is, for every $2\frac{1}{4}$ cu. ft. of rock we must drill 2 ft. of hole, or 24 ft. of drill hole per cu. yd. If the cost of drilling is 25 cts. a foot, we have $\$0.25 \times 24 = \6 per cu. yd. as the cost of drilling alone. It is seldom, however, that such narrow trenching is done. Trenches for small pipes are usually $2\frac{1}{2}$ to 3 ft. wide; two holes are usually drilled in a row, and rows are usually about 3 ft. apart. A trench 3 ft. wide with two holes in a row, and rows 3 ft. apart, requires 6 ft. of drilling per cubic yard. With drilling costing 50 cts. per ft., as it often does where hand drills are used in granite, the cost is then \$3 per cu. yd. for drilling alone. Unless the job is too small to pay for installing a plant, hand drilling should never be used in trench work, because the drilling forms such a very large part of the cost.

In a trench 6 ft. wide in hard New Jersey trap rock three holes were drilled in a row, one close to each side and one in the middle,

and the rows were 3 ft. apart, thus requiring $4\frac{1}{2}$ ft. of drill hole per cu. yd. of excavation. The drilling was done with steam drills at a cost of 30 cts. per lin. ft., for the holes were only $4\frac{1}{2}$ ft. deep, the rock was hard, and the men slow, about 35 ft. being the day's work per drill. The contractor had to drill $1\frac{1}{2}$ ft. below grade in this rock to insure having no projecting knobs of rock. While it cost \$1.35 per cu. yd. to drill the $3\frac{1}{2}$ ft. for which payment was made, to this must be added nearly 30%, or \$0.40 per cu. yd., to cover the cost of drilling the extra 1 ft. for which no payment was received, making the total cost of drilling \$1.75 per cu. yd. of pay material. About 2 lbs. of 40% dynamite were charged in each hole, making about 3.6 lbs. of dynamite per cu. yd. of pay material. The explosives thus added another \$0.40 per cu. yd., making a total of \$2.15 per cu. yd. for drilling and blasting.

In the same trap rock, where the trench was 3 ft. wide and 12 ft. deep, there were three holes in a row and rows were 4 ft. apart, requiring 2.53 ft. of hole per cu. yd. of pay excavation, plus 0.21 ft. of hole per cu. yd. of pay material to cover the cost of drilling the last 1 ft. of hole below the "neat line." Each drill averaged 45 ft. of hole in 10 hrs., and the cost was 22 cts. per ft. of hole; hence $\$0.22 \times 2.74 = \0.63 per cu. yd. was the cost of drilling. About 4 lbs. of 40% dynamite were charged in each hole, or 1.1 lbs. per cu. yd. of pay material, making the total cost 80 cts. per cu. yd. for drilling and blasting. A comparison of this cost of 80 cts. with the \$2.15 above given brings out strikingly the fact that each problem of trench work must be considered in detail by itself.

In a city where the contractor must fire comparatively small shots in order to avoid accidents to buildings and suits for damages arising from "disturbing the peace," it is seldom possible to space the holes more than 3 or at most 4 ft. apart. In trenching in soft sandstone in Newark, N. J., where the trench was 14 ft. wide and 10 ft. deep, there were five holes in a row (the distance between holes being $3\frac{1}{2}$ ft.) and rows were 4 ft. apart, making 2.4 ft. of hole per cu. yd. Each hole was charged with 4 12 lbs. of 40% dynamite, making practically 1 lb. per cu. yd. About half the dynamite was charged at the bottom of each hole, then tamping was put in, and the other half was charged up to about $2\frac{1}{2}$ ft. below the mouth of the hole. Each steam drill averaged 90 ft. of hole per 10 hrs., making the cost of drilling 18 cts. per ft. of hole, or 24 cts. per cu. yd. Including the cost of dynamite and the placing of timbers over each blast, the cost of drilling and blasting was 40 cts. per cu. yd. This is probably as low a cost for breaking rock in a wide trench as can be counted upon under favorable conditions. In this rock there was no necessity of drilling below grade.

The cost of throwing rock out of shallow trenches or of loading it into buckets to be raised by the engine of a derrick, a locomotive crane or a cableway, is somewhat greater than the cost of handling rock in open cuts. A fair day's work for one man is 6 cu. yds.

of rock handled, when there is little sledging; but the output may be only 4 cu. yds. where there is a large amount of sledging to be done.

If cableways or derricks are used for hoisting the rock, bear in mind that they will be idle most of the time, for the drilling limits the output. With a given number of drills to a cableway, estimate the number of cubic yards of rock that the drills will break per day and divide this yardage into the daily cost of operating the cableway. Thus, in a trench 4 ft. wide, if the holes are 3 ft. apart, each cubic yard of rock requires $4\frac{1}{2}$ ft. of hole, and each drill will break $13\frac{1}{2}$ cu. yds. per day where 60 ft. of hole is a day's work. With four drills per cableway the daily output is $4 \times 13\frac{1}{2} = 53\frac{1}{2}$ cu. yds. The cableway would be capable of handling several times this output were it not limited by the drilling. Notwithstanding that all this seems self-evident, I have known more than one contractor to overlook the fact that the cost of handling rock from trenches is very much greater than in open cuts where holes are farther apart and where a few drills can keep a cableway busy.

I am indebted to Mr. F. I. Winslow for the following data on trench work in Boston, Mass.: For house sewer trenches, contractors are allowed 3 ft. width, and trenches for water pipe (16 ins. or less), $2\frac{1}{2}$ ft. width. The rock is granite, and the drill holes are usually 3 ft. apart drilled along the center of the trench, but staggered a little off center. On small jobs hammer drills are used, one man holding and two striking. For a hole 10 ft. deep the starting bit is $2\frac{1}{2}$ ins. and the finishing bit is $1\frac{1}{2}$ ins. diam. A drilling gang of three men averages 8 to 10 ft. of hole in 10 hrs., although in very soft rock 20 ft. may be drilled in 10 hrs. In a trench 10 ft. deep, the rock is usually excavated in two 5-ft. benches, but some contractors drill the full 10 ft. and take it out in one 10-ft. bench. Forceite containing 75% nitroglycerin is commonly used, $\frac{1}{4}$ to 3 sticks being charged in a hole. Force account records for granite trenching, on jobs of less than 100 cu. yds. each, show that the average cost during the past 15 years has been \$2.80 per cu. yd., including excavating and piling up the rock alongside the trench. The wages paid hand-drillers were \$1.75 per 10-hr. day; and to laborers, \$1.40 per day.

I am indebted to the Harrison Construction Co., of Newark, N. J., for the following information: In a sandstone trench about 6 ft. wide the holes were spaced about 3 ft. apart, thus requiring $4\frac{1}{2}$ ft. of hole per cu. yd. In seamy rock, shallow holes 4 to 6 ft. deep were drilled, and from 2 to 3 sticks of 50% dynamite were charged, each stick being $1\frac{1}{2} \times 8$ ins. This is equivalent to 0.55 lb. per cu. yd. Where the rock was solid, the holes were drilled 8 to 10 ft. deep and the dynamite charge doubled.

Consult the sections on Water Works and on Sewers for further data on trenching.

Cost of Quarrying and Crushing Trap.—The following data relate to quarrying New Jersey trap rock and crushing it in gyratory crushers. The quarry face was 12 to 18 ft. high. The output of the following gang was 200 cu. yds. of crushed stone per 10-hr.

ROCK EXCAVATION, QUARRYING, ETC. 211

day, each cubic yard of crusher run product weighing 2,700 lbs., no piece being more than 2 in. diameter. The weight of a solid cubic yard of this trap was 4,500 lbs., so that the voids in the crushed stone were 40%. Drill holes were spaced about 5 ft. apart.

	Per day.	Per cu. yd.
1 drillers at \$2.75	\$ 8.25	\$0.041
1 helpers at \$1.75	5.25	0.026
10 men barring out and sledging	15.00	0.075
14 men loading carts	21.00	0.105
4 cart horses	6.00	0.030
2 cart drivers	3.00	0.015
2 men dumping carts and feeding crusher...	3.00	0.015
1 fireman for drill boiler	3.50	0.013
1 engineman for crusher	3.00	0.015
1 blacksmith	3.00	0.015
1 blacksmith helper	2.00	0.010
1 foreman	5.00	0.025
2 tons coal at \$3.50	7.00	0.035
150 lbs. 40% dynamite at 15 cts.	22.50	0.113
Total	\$106.50	\$0.523

Interest, depreciation and repairs would add about \$2 or \$10 more per day, or 4 to 5 cts. per cu. yd., making a total of about 58 cts. per cu. yd. There was no earth stripping.

The stone was loaded into one-horse dump carts, the driver taking one cart to the crusher while the other cart was being loaded. The haul was 100 ft. The carts were dumped into an inclined chute feeding into a No. 5 Gates gyratory crusher. The stone was elevated by a bucket elevator and screened. All stone larger than 2-in. was returned through a chute to a small No. 3 Gates crusher to be re-crushed.

I should add that the trap rock was much seamed, so that upon blasting it was broken into tolerably small chunks, so that the cost of sledging was not high considering the small size of the crusher.

Cost of Crushing at Newton, Mass.—A. F. Noyes, City Engineer of Newton, Mass., gives the following cost data for the year 1891, on four jobs of crushing stone and cobbles for macadam. On jobs A and B the stone was quarried and crushed; on jobs C and D cobblestones were crushed. A 9 X 15-in. Farrel-Marsondon crusher was used, stone being fed in by two laborers. A rotary screen having ½, 1 and 2½-in. openings delivered the stone into bins having four compartments, the last receiving the "tailings" which had failed to pass through the screen. The broken stone was measured in carts as they left the bin, but several cart loads were weighed, giving the following weights per cubic foot of broken stone:

	Size			
	¾-in. Lbs.	1-in. Lbs.	2½-in. Lbs.	Tailings. Lbs.
Greenish trap rock, "A"	95.8	84.3	88.3	91.0
Conglomerate, "B"	101.0	87.7	94.4
Cobblestones, "C" and "D"	102.5	96.0	99.6

A one-horse cart held 26 to 28 cu. ft. (average 1 cu. yd.) of broken stone; a two-horse cart, 40 to 42 cu. ft., at the crusher.

	Job			
	A.	B.	C.	D.

*Loading and hauling in wheelbarrows.

NOTE.—"A" was trap rock; "B" was conglomerate rock; "C" and "D" were trap and granite cobblestones. Common laborers on jobs "A" and "D" were paid \$1.75 per 9-hr. day; on jobs "B" and "C," \$1.50 per 9-hr. day; two-horse cart and driver, \$5 per day; blacksmith, \$2.50; engineer on crusher, \$2 on job "A," \$2.25 on "B," \$2.00 on "C," \$2.50 on "D"; steam driller received \$3, and helper \$1.75 a day; foreman, \$3 a day. Coal was \$5.25 per short ton. Forcite powder 11½ cts. per lb.

Cost of Quarrying and Crushing Quartzite.—Mr. W. G. Kirchoffer gives the following data on the cost of quarrying and crushing quartzite for macadam, in 1903, at Baraboo, Wis. The plant was a municipal plant operated by day labor, and the costs were somewhat higher than under contract work. The crusher was a No. 3 Austin jaw crusher, 12 x 16-in. opening. Three sizes of screen holes in the rotary screen were used: ¾-in., 1¾-in. and 2½-in. The first cost of the plant was as follows, in 1901:

Crusher	\$ 900
Bins	108
Steam drill	218
Small tools	108
	<hr/> \$1,334

The output of the crusher by years has been:

	Year		
	1901.	1902.	1903.
Total output, cu. yds.	1,920	3,700	4,882
Days worked	47	70	88
Output per day, cu. yds.	41	53	55½

In the year 1901, about 10% of the stone was screened out and

thrown away. The wages paid per 10-hr. day were: Laborers, \$1.50; quarrymen, \$1.75; drill-runner, \$2; engineman and engine, \$2.50. The stone was measured in wagons built to hold just 1½ cu. yds., by weight, 3,900 lbs., and the following costs for 1903 are based upon wagon measurement of the stone:

	Per cu. yd.
Quarry rent	\$0.0207
Labor quarrying, including foreman.....	0.3200
Labor crushing	0.1980
Tools	0.0148
Dies for crusher	0.0626
Dynamite (60% at 25 cts. per lb.), caps and fuse.....	0.0910
Rent of engine and wages of engineman.....	0.0635
Fuel for engine, \$4.60 per ton.....	0.0477
Oil and waste	0.0033
Hauling water and supplies	0.0489
Supplies	0.0137
Superintendent of crusher	0.0476
Depreciation of plant	0.0736
Total	\$1.0074

The cost of hauling 2½ miles to the street was 50 cts. per cu. yd., wages of team and driver being \$3 a day.

The cost of the macadam pavement, including stone, hauling, grading, spreading stone, claying and rolling, has been a little less than 50 cts. per sq. yd. The macadam was 8 ins. thick at the center and 6 ins. at the gutters, measured after rolling.

Cost of Quarrying and Crushing Limestone for Macadam.—The cost of operating a small quarry, and crushing with a portable or semi-portable crusher is obviously much higher than where a large plant is used. For some time to come the greater part of road-metal crushing will be done with small plants, under conditions such as I am about to describe, and at costs not far differing from those that will be given.

In quarrying limestone, where the face of the quarry was only 5 to 6 ft. high, and where the amount of stripping was small, one steam drill was used. This drill received its steam from the same boiler that supplied the crusher engine. The drill averaged 60 ft. of hole drilled per 10-hr. day, but was poorly handled and frequently laid off for repairs. The cost of quarrying and crushing was as follows:

Quarry.	
1 driller	\$ 2.50
1 helper	1.50
1 man stripping	1.50
4 men quarrying	6.00
1 blacksmith	2.50
½ ton coal at \$3.....	1.00
Repairs to drill60
Hose, drill steel and interest on plant.....	.90
24 lbs. dynamite	3.60
Total	\$20.10

Crusher.	
1 engineman	\$ 2.50
3 men feeding crusher	3.50
6 men wheeling	9.00
1 bin man	1.50
1 general foreman	3.00
1/2 ton coal at \$8	1.00
1 gallon oil25
Repairs to crusher	1.50
Repairs to engine and boiler	1.00
Interest on plant	1.00

Total\$24.25

Summary --

	Per day.	Per cu. yd.
Quarrying	\$20.10	\$0.84
Crushing	24.25	0.41
Total for 60 cu. yds.....	\$43.85	\$0.75

The "4 men quarrying" barred out and sledged the stone to sizes that would enter a 9 x 16 in. jaw crusher. The "6 men wheeling" delivered the stone in wheelbarrows to the crusher platform, the run plank being never longer than 150 ft. Two men fed the stone into the crusher, and a binman helped load the wagons from the bin, and kept tally of the loads. The stone was measured loose in the wagons, and it was found that the average load was 1 1/2 cu. yds., weighing 2,400 lbs. per cu. yd. There were 40 wagon loads, or 60 cu. yds. crushed per 10-hr. day, although on some days as high as 75 cu. yds. were crushed. The stone was screened through a rotary screen, 9 ft. long, having three sizes of openings, 1/2-in., 1 1/4-in. and 2 1/2-in. The output was 16% of the smallest size, 24% of the middle size, and 60% of the large size. All tailings over 2 1/2 ins. in size were re-crushed.

It will be noted that the interest on the plant is quite an important item. This is due to the fact that, year in and year out, a quarrying and crushing plant for roadwork seldom averages more than 100 days actually worked per year, and the total charge for interest must be distributed over these 100 days, and not over 300 days as is so commonly and erroneously done.

The cost of stripping the earth off the rock is often considerably in excess of the above given cost, and each case must be estimated separately. Quarry rental or royalty is usually not in excess of 5 cts. per cu. yd., and frequently much less.

The dynamite used was 40%, and the cost of electric exploders is included in the cost given. Where a higher quarry face is used the cost of drilling and the cost of explosives per cu. yd. is less. Exclusive of quarry rent and heavy stripping costs, a road contractor should be able to quarry and crush limestone or sandstone for not more than 75 cts. per cu. yd., or 62 cts. per ton of 2,000 lbs., wages and conditions being as above given.

The labor cost of erecting bins and installing a 9 x 16 jaw crusher, elevator, etc., averages about \$75, including hauling the plant two or three miles, and dismantling the plant when work is finished.

The first cost of a quarrying, crushing and macadam road building plant is given in following paragraph.

Price of Road Building Plant.—The following gives the first cost of a typical portable plant for quarrying and crushing rock, grading, hauling and building a macadam road:

Crusher Plant—	
1 jaw crusher (9 x 15 in.), with rotary screen..	\$1,100
Portable bins	200
Engine to drive crusher (15 HP.).....	200
Boiler on wheels (20 HP.).....	600

Total crusher plant\$2,100

Quarry Plant—	
2 steam drills at \$250.....	\$ 500
Steam pipe, waterpipe, etc.....	150
Quarry and blacksmith tools.....	150
Steam boiler (15 HP)	400

Total quarry plant\$1,200

Road Plant—	
6 dump wagons for hauling stone at \$125....	\$ 750
6 dump wagons for grading at \$125.....	750
2 leveling scrapers at \$100.....	200
12 wheel scrapers at \$50.....	600
12 drag scrapers, shovels, picks, etc.....	150
1 steam roller	2,500
2 sprinkling wagons at \$300.....	600
Gasoline pump and portable water tank.....	500

Total road plant\$5,850

Grand total\$9,150

Cost of Jaw Crusher Renewals.—Mr. Thomas Aitken gives the following data as to costs in England, for a 9 x 16-in. jaw crusher (Baxter) whose first cost complete was \$1,500. The crusher averaged 66 long tons of trap per 10-hr. day.

	Life in tons crushed.	First cost of part.	Cost per long ton, cents.
Upper jaws (reversible).....	8,000	\$11	0.13
Lower jaws (reversible).....	4,000	11	0.26
Top rotary screen (plates ¼ in.)..	24,000	30	0.12
Lower rotary screens	48,000	23	0.04
Elevator belt (6 ply; 26 ft. long), plates, etc.	32,000	60	0.18
Elevator buckets (25).....	8,000	10	0.12
Toggles and bearings, etc.	8,000	14	0.16

Total1 01

This crusher has a capacity of 80 tons (of 2,240 lbs.) per day, is mounted on wheels, and has two short rotary screens (one above the other) mounted on the same framework with the crusher itself, and it carries a very small bin, also on the same frame. The machine is entirely self-contained, and thus is readily portable. Our American practice is to have large separate bins (sometimes on wheels), and consequently a much longer elevator. While the first cost of our American crushers of the same size is also about \$1,500 complete, our repair parts will average nearly double the cost given by Mr. Aitken for English conditions.

Aitken states that 1 hp. (nominal) for each ton crushed per hour will drive the Baxter crusher, but it is noteworthy that he gives a coal consumption of 720 lbs. per day, which indicates far more than 8 hp.

Cost of Quarrying and Crushing Limestone, Missouri.*—Mr. Curtis Hill gives the following relative to work done by contract in 1908 for the Missouri Highway Department. The stone was a hard, bluish gray limestone. Two quarries were opened up near the road, and a total of 13,000 cu. yds. of crushed stone produced.

Quarrying—		Cost per cu yd.
Foreman and timekeeper, at.....	\$0.40	\$0.056
Drillers (hand), at17 1/2	.018
Drillers (steam), at17 1/2	.031
Laborers, at17 1/2	.224
Teams, at35	.021
Powder, lbs. at10	.059
Caps, at10	.002
Fuse, ft., at.....	.01
Watchman, at15	.017
Water boy, at10	.012
Quarry rent, at.....030
Total quarrying		\$0.473
Crushing—		
Foreman and timekeeper40	.064
Laborers17 1/2	.121
Engine and engineman40	.067
Watchman15	.007
Total crushing		\$0.259
Grand total		\$0.731

This does not include plant interest, repairs and depreciation, nor insurance of men.

The stone was screened through three sizes of hole, 3/4, 1 1/2 and 3-in.

The crusher was a portable jaw crusher, and its output was 65 cu. yds. per 10-hr. day.

The organization was about as follows:

- 1 quarry foreman.
- 1 steam driller.
- 1 hand driller (3/4 time).
- 8 laborers, quarry.
- 1 team (3/4 time).
- 1 water boy.
- 1 watchman.
- 1 crusher foreman.
- 4 laborers at crusher.
- 1 engineman on crusher.

Cost of Crushing and Hauling Cobblestones.†—Mr. W. A. Gillette is author of the following:

It may be of interest to builders of macadam roads or crushers

**Engineering-Contracting*, Aug. 4, 1909.

†*Engineering-Contracting*, April 28, 1909.

of stone to know how cheaply the work can be done with a good small plant and when the supervision of the plant is intelligently administered. My experience in the above class of work leads me to believe that few plants of a capacity similar to the one which shows the output I will give below are giving such satisfactory results. The plant in question is owned by the City of Ventura, Cal., and the rock is used in the construction of petrolithic macadam.

The engineering of the entire work has been done by J. B. Waud, and Mr. James M. Montgomery is the contractor. Mr. Montgomery has an exceptionally fine lot of stock, and the organization of his work is about as near perfection as it could be.

While looking over the work at Ventura the writer took occasion to make an inquiry regarding the cost per cubic yard for stone delivered on the street. This question was brought about from the fact that the work was being done at an exceptionally low cost, and it was hard to understand just why the cost was so much less than that of other similar construction.

I was told that the cost of the rock delivered on the street was something less than 50 cts. per cu. yd. It hardly seemed possible, when it was known that the average haul from the crusher to the work was about a mile, while the tough cobbles which are being crushed are gathered on the ocean beach and hauled in $1\frac{1}{2}$ -cu. yd. dump wagons to the crusher, a distance of about 1,500 ft., two teams with two wagons and drivers being used for this purpose.

Eight laborers are used to load the cobbles into the wagons; three men and the foreman do the work at the crusher and bins. The power to operate the crusher is electricity.

Five teams and drivers with dump wagons holding 2 cu. yds. each haul the crushed stone to the streets.

On this particular day all of the crushed stone was hauled $\frac{1}{4}$ mile and the screenings were hauled $1\frac{1}{4}$ miles. The wagons were heaped up so that they reached the street more than full. A good part of this haul was over very rough roads, so the rock was well settled in the wagon boxes.

The wages paid are as follows:

Two-horse team, wagon and driver, \$4.50 for 9 hrs.

Foreman, \$4 per day.

Laborers, \$2 per day.

The following is an itemized statement of the 9-hr. day's work:

One foreman, at \$4.00 per day.....	\$ 4 00
Eleven laborers, at \$2.00 per day.....	22 00
Two teams hauling cobbles to crusher, at \$4.50 per day.....	9 00
Five teams hauling crushed stone to street, at \$4.50 per day..	22 50
Electric power, 67 kw. hours, at 3 cts.....	2 00
Engine oil	1 00

Total\$60.50

The total output for a large day's run was 182 cu. yds., as measured in the wagon boxes at a cost of \$60.50, or 45.8 cts. per cu. yd.

delivered on the street, exclusive of plant interest and depreciation. The plant cost \$3,000. It consists of a No. 3 Austin gyratory crusher, having two $8\frac{1}{2} \times 24$ -in. openings, driven by an electric motor.

Where the rock was crushed so that all of it would pass through a 2-in. ring the average output was 90 cu. yds. per 8-hr. day, or 67 cts. per cu. yd. for labor, hauling and power.

The cost of interest and maintenance of plant is not included.

Cost of Quarrying and Crushing Trap, and Ballasting, D., L. & W. Ry.*—Mr. Lincoln Bush is author of the following:

Early in 1905 the D. L. & W. Ry. Co. acquired by purchase near Boonton, N. J., a granite quarry and crusher plant, together with other equipment in the way of cars, machinery, etc., that were utilized by a contractor in connection with the construction of a large masonry dam for a reservoir. This work having been completed by the contractor, the Lackawanna Railroad Company acquired about 3 miles of railroad running from its main line to the quarry plant, together with about 56 acres of ground, tracks at crusher plant, etc. In adapting this plant to our use and rearranging the tracks and crusher layout to meet our requirements, we expended at the outstart \$21,904.33, and sold from the contractor's outfit certain equipment not required by us, which sale netted us \$18,159.31, making the net cost to us of the quarry and plant at the time we started operating the crusher \$36,245.02.

The material obtained from this crusher plant is a very good quality of New Jersey granite, weighing 2,795 lbs. per cu. yd. of crushed stone.

The quarry was well opened up when we acquired it from the contractor, and the face of the quarry has a depth of from 20 to 60 ft. and a length of about 2,200 ft. The stripping on top of the quarry will average about $2\frac{1}{2}$ ft.

The crusher machinery was manufactured by the Allis-Chalmers Co., and consists of one No. 3 and one No. 6 crusher, with a large bucket conveyor for conveying the broken stone from the crusher to the screens. There is one large 48-in. diameter screen, consisting of three sections, each 4 ft. in length, with ringings from $\frac{1}{2}$ in. to $2\frac{1}{2}$ ins. in diameter and a dust jacket for separating the materials. Materials which pass through the $\frac{1}{2}$ -in. ringing are not used for track ballast. The ballast product is conveyed on a Robins belt conveyor and deposited into a system of bins; the finer material and dust pass directly over the dust jacket into the dust bin.

The percentage of fine materials, i. e., dust and $\frac{1}{2}$ -in. stuff, runs from 13% to 14% of the total output.

The grades of tracks at the crusher plant are so arranged as to handle the cars after being placed by gravity.

There is a powder magazine located on the property which has a storage capacity for about 10 tons of powder and explosives.

**Engineering-Contracting*, March 24, 1909.

There is also a water system for the boilers and a sprinkling plant to keep down the dust.

The maximum grade of the track connecting our main line with the quarry is 3%, ascending to the quarry, and in handling our ballast we have been utilizing a locomotive which will handle 14 empty Rodger ballast cars up this 3% grade.

The larger part of the stone is handled from the quarry to the crusher plant by means of a derrick system, the face of the quarry being located quite close to the crusher plant. We have in use 6 large derricks with 90-ft. masts, which, with 6 hoisting engines operated in connection with the derrick system, handle the stone in large stone boxes. The stone is quarried from the top of the face by a stepping system.

To pass into the No. 6 crusher the stone has to be broken up in sizes from 16-in. to 20-in. The breaking of the material is done with a system of block hole drills, placing holes from 6 ins. to 12 ins. apart, depending upon the size of the stone to be broken. We use from 3 to 6 block hole drills per day in breaking up the larger stone and some of the smaller stones are sledged instead of being block holed.

In addition to the derrick system at this plant we also have a car system, by means of which cars are loaded with stone from the quarry are dropped by gravity to the crusher. These cars have from 12 to 16 cu. yds. capacity, and when the cars reach the crusher plants are dumped by one of the derricks. The bottom of these cars is constructed of wood and metal, with a chain attached, and the false bottom of the car is picked up on one end by the derrick, and the stone dumped by this means without manual handling. After the cars have been dumped at the crusher they are returned to the quarry by a haulage system, operated by a hoisting engine. The stripping from the top of the quarry is disposed of by piling it back from the face of the quarry.

In operating the quarry and crusher we have employed an average of 125 men, including rock men, drill men, engineers, mechanical men and laborers required at the quarry and crusher. We employ two blacksmiths for handling the drill work and a pipefitter for taking care of the steam-pipe system and steam drills. One mechanical foreman with the necessary help has charge of the crushing plant and one general foreman has charge of the quarry. One engineer handles the engine in the crusher plant and one fireman does the firing.

We utilize a 150-hp. boiler for generating steam for the drills, and in addition to this we have two 150-hp. boilers for furnishing the balance of power for the derricks and at the crushers.

We started operating the quarry and crusher plant in May, 1905. The plant was shut down on January 15, 1906, and operations resumed in March, 1906. The detailed statements of the cost of quarrying and crushing stone at this plant have been carefully kept and are reliable as to the cost as well as to output. The cost includes the quarrying and crushing, and includes the material loaded on cars at the bins.

The costs were as follows:

Month and Year.	Output, cu. yds.	Average cu. yds. per day.	Cost per cu. yd. for quarrying, cta.	Cost per cu. yd. for crushing, cta.	Cost per cu. yd. quarrying and crushing.
May, 1905.....	6,637	346	46.2	8.9	55.1
June, 1905.....	7,048	371	50.6	7.6	58.2
July, 1905.....	6,267	341	55.9	6.6	62.5
August, 1905....	8,722	323	51.1	5.3	56.4
September, 1906.	7,617	270	55.2	6.6	61.8
October, 1905...	6,821	243	56	7.2	63.2
November, 1905.	6,219	235	47.9	5.8	53.7
December, 1905.	5,882	249	57.5	7.6	65.1
January, 1906...	3,233	269	39.2	6.2	45.4
April, 1906.....	7,516	301	61.6	6.7	68.3

June, 1906.....	10,622	409	47	5	52
July, 1906.....	10,894	426	45.5	6	51.5
August, 1906....	10,183	277	49	6	55
Average.....		307	49	6.5	55.5

The average cost for the four months of May to August, 1906, was as follows:

	Per cu. yd. cta.
Quarrying:	
Labor	38.4
Supplies	6.6
Total quarrying	45.0
Crushing:	
Labor	3.5
Supplies	2.5
Total crushing	6.0
Grand total	51.0

These costs do not include interest and depreciation of plant, but do include all other items, even to current repairs.

We have used the crushed stone from this plant at various points along our line on the Morris and Essex Divisions, and during the present season we put on a ballast gang for ballasting a $4\frac{1}{2}$ -mile section of double track located between Hopatcong and Wharton, N. J.

In handling the ballast on this $4\frac{1}{2}$ -mile section we had an average of 31 laborers at 14 cts. per hour per day of 10 hrs. and one foreman at \$75 per month. In addition to the regular ballast gang we had 8 section laborers on the $4\frac{1}{2}$ -mile section that were employed in digging out, changing ties, placing drain tile and filling for changes in alignment and easement curves.

The amount of ballast used on the $4\frac{1}{2}$ -mile section of double track was 28,458 cu. yds., or an average of 6,324 cu. yds. per mile of double track. The average distance which the ballast was hauled from the crusher to the section ballasted was 13 miles. On the $4\frac{1}{2}$ -mile section of track ballasted there was a total length of curve line of 1.56 miles and a total length of tangent

of 2.94 miles. We used in this work 24 Rodger ballast cars, and in figuring the cost of transportation the cars were placed at a value of \$600 each. Our records show a cost of $5\frac{1}{2}$ cts. per cu. yd., covering transportation charges, interest on the Rodger ballast cars valued at \$600 each at 5%, plus interest at 5% on the net investment of the quarry and crusher plant. The cost for quarrying, crushing and loading cars at the crushing plant was 55 cts. per cu. yd.; the cost of placing ballast under track, including lining, surfacing and dressing, was $20\frac{1}{2}$ cts. per cu. yd., making a total cost per cubic yard of the ballast in the track of 81 cts. for the $4\frac{1}{2}$ -mile section above described.

On the west end of our Buffalo Division we have an accurate record of the cost of 27,120 cu. yds. of crushed limestone ballast put in on a stretch of double track during the season of 1906. For this work we purchased the crushed stone delivered to us in our own Rodger ballast cars at an average cost of \$0.8017 per cu. yd., and received an average of 222 cu. yds. per day, the quarry being located on our own line. Thirty Rodger ballast cars were used for this work and the average haul was 12.4 miles. The ringing used in preparing this ballast was from $\frac{3}{4}$ in. to $2\frac{1}{4}$ ins. diameter and the stone weighed 2,410 lbs. to the yard. As above stated, we received on an average 222 cu. yds. per day, and a larger quantity per day would have reduced the cost per yard somewhat. In comparing this cost with the cost of ballasting with materials obtained from the Boonton crusher plant, it will be noted that the ballast on cars from the Boonton plant cost practically 5 cts. per cu. yd. less than the material used on the Buffalo Division. The work on the Buffalo Division cost a total of 81.1 cts. per cu. yd., in track, which cost included the material, engine service, labor, tie renewals and spacing, and interest on ballast car equipment.

Cost of Quarrying, Crushing and Ballasting, and Life of Ballast.*
—From tests of trap and other rocks, it is seen that a material saving can be effected by the use of trap for ballast purposes. Less stone will be required to maintain the track, and it can be used in smaller sizes, as its higher percentage of hardness and toughness will insure less breaking under traffic and tamping. Figures taken from comparison of line and surface in trap with that in stone whose quality is about the same as limestone, show that line and surface cost approximately \$20 less per mile in trap than in limestone.

Cost of Plant.—From published figures, the cost of building a plant of 1,000 tons daily capacity, and its cost of operation to quarry, is as follows:

Capacity, 1,000 tons daily.....	300,000 tons annually
900 cu. yds. trap per 10-hr. day.....	270,000 cu. yds. annually
Crushers, 4, 250-ton Farrel, at \$1,250.....	\$ 5,000
Engines, 4, 60-hp., 14 x 12, at \$500.....	2,000
Foundations	100
Beltng, 12-in., 200 ft., at \$2.75.....	550

**Engineering-Contracting*, Sept. 1, 1909, abstract of a report to the Am. Ry. Eng. and Mn. of Way Assoc.

Boilers, 2, 200-hp. and setting.....	7,500
Steam fittings	4,000
Boiler house	2,500
Engine house	1,500
Stack	2,000
Scales, 60-ft., including foundations and timber.....	1,225
Bins	600
Elevators with platforms, 4, at \$1,500 (for tailings).....	6,000
Pump for water supply, 5,500 gals. per hour.....	200
Tank, 50,000 gals.	1,200
Steam drills, with tripods connecting hose, 20, at \$245.....	4,900
Screens, rotary, 54-in., 4, at \$950.....	3,800

\$158,571

This shows a cost per yard of 59 cts.

With this figure, the estimated saving shown from the use of trap rock (Gabbro) over limestone now used, from Martinsburg quarry, on the Baltimore & Ohio Railroad, in a 16-mile section, double track, or 32 miles of single track, based on changing the

entire ballast in a five-year period, and using 2,200 cu. yds. of trap rock per mile, 3-in. under the tie, would be as follows:

Gabbro—	
Quarrying	\$0.60
Placing in track.....	.15
Average haul, 18 miles, at .001.....	.02
<hr/>	
Total estimated cost per cu. yd.....	\$0.77
Limestone—	
Quarrying	\$0.55
Screenings, 33%18
Placing in track.....	.15
Average haul, 98 miles, at .001.....	.10
<hr/>	
Total actual cost per cu. yd.....	\$0.98

SUMMARY.

Limestone, 14,080 cu. yds., at 98 cts.....	\$13,798.40
Gabbro, 14,080 cu. yds., at 77 cts.....	10,841.60

Saving per year during ballasting, due to use of trap rock\$ 2,956.80

As to saving in maintenance 300 cu. yds. of trap rock per mile per year will maintain track as efficiently as 400 cu. yds. of limestone.

32 miles single track X 400 cu. yds. limestone X 98 cts.....	\$12,544
32 miles single track X 300 cu. yds. trap rock X 77 cts.....	7,392

Saving per year due to use of trap rock after track is fully ballasted\$ 5,152

Saving in line and surface, 32 miles, at \$20..... 640

Total saving per year after track is fully ballasted....\$ 5,792

The saving in maintenance labor during ballasting would be:

1st year	\$128
2d year, 6.4 miles X \$20.....	256
3d year, 12.8 miles X 20.....	384
4th year, 19.2 miles X 20.....	512
5th year, 25.6 miles X 20.....	640
<hr/>	
Total five years labor saving during ballasting (maintenance)	\$ 1,280.00
Five years saving in first cost, due to use of trap rock..	14,784.00

Total five years saving during ballasting.....	\$16,064.00
Average saving per year during ballasting.....	3,212.80
Saving per year after fifth year	5,792.00

These figures give an idea of the savings which may be effected by going into such questions thoroughly, and getting accurate data. Such comparisons may be worked up for stone, gravel and cinder, and estimate made which will show a railroad management how far they are justified in going into such economies.

[There is clearly an error in the assumption that it will take anything like 300 or 400 cu. yds. of stone yearly to maintain a mile of ballasted track. See the section on Railways for cost of maintenance of way.]

Cost of Crushing with City Plant, Boston.—In *Engineering-Contracting*, Aug. 11, 1909, is a long abstract from the Metcalf & Eddy report to the Boston Finance Commission, of which the following is only a meager abstract:

The crusher plant occupies an area of 570,000 sq. ft., pur-

chased in 1882 for \$30,000 and having an assessed value in 1907 of \$79,800. The tract is used in part for other than quarrying and crushing purposes. The plant consists mainly of a 30 x 12-in. Farrel crusher, a 72 x 16-in. Atlas engine, a 66-in. x 17-ft. tubular boiler, the usual elevators, bins, extra parts and tools, and of three large and one baby steam drills. The estimated cost of the plant was \$16,653; interest was calculated at 4% and depreciation at 6.75% annually, which gives an amount of \$1,791, which in the costs following was applied on a monthly basis. The charge for steam drills is based on a rental of 50 cts. per working day.

Force Employed.—The force employed, with wages, was in general as follows:

Labor at Ledge:		Per day.
1 sub-foreman, at \$3.50.....	\$	3.50
1 blacksmith, at \$3.....		3.00
1 blacksmith's helper, at \$2.25.....		2.25
3 steam drillers, at \$2.25.....		6.75
3 steam drillers' helpers, at \$2.25.....		6.75
10 stone breakers, at \$2.25.....		22.50
5 hand drillers, at \$2.25.....		11.25
1 powderman, at \$2.25.....		2.25
9 loaders, at \$2.25.....		20.25
Total	\$	78.50
Labor at Crusher:		
1 engineer, at \$3.50.....	\$	3.50
1 fireman, at \$3.25.....		3.25
1 welgher, at \$3.50.....		3.50
1 oiler, at \$2.25.....		2.25
2 feeders, at \$2.25.....		4.50
1 pitman, at \$2.25.....		2.25
Total	\$	21.50
Teaming:		
6 single teams, at \$3.50.....	\$	21.00
Total	\$	121.00

The force consisted largely of men who were in some degree skilled in rock work. The majority of the men were young and all were vigorous and skilled to such an extent that the force as a whole was skillful and efficient. There was a marked lack of interest on the part of some of the employees, which undoubtedly had its effect in reducing the amount of work done considerably below the amount which would be done under contract conditions; on the other hand it should be stated that some of the men took a lively interest in the work and did their full duty.

In this connection it should be noted that the capacity of the bins being only about 400 tons, they were sufficient only for about 2½ days output of the crusher as it was operated. The normal capacity of the crusher is claimed by the manufacturers to be about 250 tons per day, while the maximum output for any one day during this test was 225 tons.

During three weeks in July, three drills were operated, but this was found to be inadvisable because the force of laborers was unable to handle the rock as fast as it was blown out.

ROCK EXCAVATION, QUARRYING, ETC. 225

The duration of this test was from May 28 to September 10, 1908, inclusive. The work accomplished during the test may be summarized as follows:

Work Done:

Stripping removed (a large part of the stripping had been done prior to the beginning of this test and is not included herein).....	384	tons
Holes drilled (2½-in. diameter) by steam drill.....	4,160.1	ft.
Unbroken stone on hand at beginning of test.....	none	
Unbroken stone on hand at expiration of test (estimated)	200	tons
Broken stone ready for crusher at expiration of test..	none	
Broken stone on hand at expiration of test.....	none	
Total output of crushed stone during test:		
Dust	1,970	tons (22%)
Stone	6,983	tons (78%)
Total	8,953	tons

Total cost of test..	\$9,526.60	

*Does not include estimated cost of stripping done prior to beginning of test, amounting to \$223.83, and does not include cost of quarrying 200 tons of stone remaining unbroken at end of test, amounting to \$50.

The report states that large stone contractors in the vicinity of Boston sell stone f. o. b. cars at about one-half the above given cost with city forces. Yet this test was made with the full understanding that it was to be a crucial test of the city forces.

Data on Jaw Crushers.—The size of jaw crushers is commonly denoted by the size of opening through which the stone passes to the jaws. A 9 x 15-in. crusher is one having an opening 9 ins. wide by 15 ins. long; which is the common size for portable plants. To move such a crusher a few miles from one location to another, set up the bins, etc., preparatory to crushing, costs about \$75, according to the author's experience. The main part of this cost consists in tearing down and rebuilding the bins, mounting the rotary screen and adjusting the bucket elevator. There are several makes of portable bins on wheels now in the market, and with

these the cost of moving should be much reduced. A large bin capacity, however, is desirable to "tide over" any irregularities in the hauling and in the operation of the crusher itself. Bins should always be used to save the cost of shoveling the broken stone into wagons.

Data on Gyratory Crusher.—The gyratory crusher is now largely used on large permanent plants. The following are the sizes of the style "D" Gates gyratory crusher:

Size No.	Diameter at top out to out.		Size of each receiving opening.	Weight of crusher, lbs.	Tons per hr. to 2½-in. size.	HP. for crusher, elevator and screen.
1	3 ft.	5 ins.	5 × 13 ins.	5,500	4 to 8	8 to 10
2	3 ft.	10 ins.	6 × 21 ins.	8,000	6 to 12	12 to 15
3	4 ft.	6 ins.	7 × 22 ins.	14,000	10 to 20	20 to 25
4	6 ft.	8 ins.	8 × 27 ins.	21,000	15 to 30	25 to 30
5	7 ft.	10 ins.	10 × 30 ins.	30,000	25 to 40	30 to 40
6	8 ft.	7 ins.	11 × 36 ins.	42,000	30 to 60	40 to 80
7½	10 ft.	8 ins.	14 × 45 ins.	63,000	75 to 125	75 to 125
8	11 ft.		18 × 63 ins.	94,000	125 to 200	100 to 150

The output is given in tons of 2,000 lbs. per hour of rock crushed to pass a 2½-in. ring.

In the section on Concrete will be found the cost of crushing with a No. 7 Gates crusher for a retaining wall on the Chicago Canal. The first cost of the crusher was \$12,000. Its output averaged 210 cu. yds. per 10 hr. day. The crusher was capable of a much greater output, for we have already recorded a 200 cu. yd. daily output with a No. 5 Gates (see page —), which is itself not a big record.

In large crushing plants the general practice is to have one large gyratory crusher that receives the big chunks of rock, and a smaller gyratory, or a jaw, crusher that re-crushes all that does not pass through a 2½ or 3 in. screen.

The following data of output were published in *Engineering-Contracting*, July 21, 1909, and relate to limestone.

The Lake Shore Stone Co., Belgium, Wis., have a plant consisting of a No. 9 Gates crusher and a No. 6 Austin, and their average output of all sizes of stone up to 2½ ins. is 600 cu. yds. per 10 hrs., with a maximum output of 750 cu. yds. The stone is fed to the crusher from a hopper by one man. Stone is delivered to the hopper by cars, 44 men being engaged in loading these cars. The stone is a very hard dolomitic limestone.

The Elk Cement & Lime Co., Petoskey, Mich., have a plant of one No. 5 Austin and a No. 3 Gates. They break 450 tons per 10 hr. day, the maximum output being 600 cu. yds. Two men feed the crusher. No crushed stone is larger than 2½ ins., hard limestone.

Holmes and Kunneke, Columbus, O., run a No. 3 Austin. The output is 80 to 120 cu. yds. per 10 hr. day, no stone being over 2 ins. in size. Two men feed the crusher. The rock is hard limestone.

A No. 8 Gates gyratory crusher having a hopper 11 ft. in diameter, operating at a speed of 140 gyrations per minute, and having a total weight of 45 tons, was installed in 1896 at the quarries of the

Pittsburg Limestone Co., Newcastle, Pa. Mr. Geo. W. Johnson, president of the company, states that in 14 mos. the output was 556,000 long tons of limestone crushed for blast furnaces. The best month's work was 47,473 tons in August, 1896, the average of the 14 mos. being slightly less than 40,000 tons per month. During the 14 mos. only 14 days were lost. The best day's work was 2,350 long tons in 10 hrs. I have been unable to secure a statement as to the size of the broken stone, but stone crushed for a blast furnace is larger than for macadam, ballast or concrete, usually being about 6 ins. diameter.

Cost of Breaking Stone by Hand.—I have found that in breaking limestone, a good 10 hrs. work for a skilled man is 3 cu. yds. broken to 2-in. sizes, but 2 cu. yds. are all that an inexperienced man can break.

Aitken states that in England a good hand-breaker can produce 3 to 4 cu. yds. of ordinary macadam per day "out of such material as flints, the harder limestones, field stones and river gravel." He says that 2 to 3½ cu. yds. of brittle whinstone, or ¾ to 1½ cu. yds. of basalt, granite and the tougher kinds of whinstone, constitute a good day's work.

In *Engineering-Constructing*, Sept. 15, 1903, the results are given of a test (in England) with different kinds of hammers used to break quartzite. It was found that chisel hammers produced 28% less fines (under 1½ in. size) than round hammers, the percentage of fines with the chisel hammers being only 5½% of the total of 500 tons broken, as compared with 7½% with round hammers.

Diamond Drilling.—For determining the nature of bridge foundations, the character of proposed canal or railway excavations and for prospecting for mineral deposits, the diamond drill is an invaluable machine. The bit of a diamond drill consists of a number of diamonds mounted on the end of a hollow tube. This bit is rotated by hand, steam, air or electric power, while at the same time water is pumped down the hollow drill rods and passes up outside of the rods, carrying away the rock dust made by the grinding of the diamonds against the rock. The bit cuts an annular channel, leaving a core of rock inside the core barrel. When the drill has penetrated the rock a distance of 5 to 10 ft., the drill rods are raised and the act of raising them breaks off the rock core, which is brought to the surface in the core barrel and kept for examination.

The diamonds are preferably black diamonds, known in the trade as "carbons": but where the rock is soft, white diamonds, known as "bortz," may be used. Sometimes both kinds are used in one bit. A bit usually has 6 to 8 carbons weighing 1 to 1½ carats each. Small stones are not economical because after a carbon has been worn down so that it weighs less than about ½ carat it cannot be reset. In selecting carbons reject those showing a cokey structure, also those having thin, sharp edges. Carbons having straight edges with sides forming an obtuse angle of 95° to 140° are most durable. The cleavage should be tested with a pair of hand pincers. Old stones that have been used are to be preferred since a poor

stone will break in use, and no test is so satisfactory as the test of usage. The carbons selected for a bit should be quite uniform in size.

When diamond drilling was first introduced into this country it was predicted that it would be used exclusively for drilling blast holes, and in fact diamond drills were used on the Sutro tunnel for a while, and in sinking one or two shafts by the "long hole" method, which involved drilling holes several hundred feet deep, filling them with sand, then removing the sand for about 8 ft., charging with powder, firing, and so on. The development of machine drills using steel bits and the steady rise in price of carbons have together shown these early predictions to have been fathered by hope rather than by reason.

The following cost data on diamond drilling have been abstracted from my book on "Rock Excavation":

The sizes of holes and cores are as follows:

Hole, diam. in ins.....	1 1/8	1 1/4	1 3/8	1 7/8	2 1/8	2 3/8	2 9/16
Core, diam. in ins.....	15/16	1 1/16	1 1/8	1 7/16	1 7/8	2	2 1/8

Price of Diamonds.—In 1873 the price of carbons per carat was \$8 to \$12. I am indebted to the Standard Diamond Drill Co., of Chicago, and to the Yawger-Lexow Co., of New York, for the following statements as to the average cost of carbons per carat from 1895 to 1903:

1895.	1896.	1897.	1898.	1899.	1900.	1901.	1902.
.....	\$36	\$50	\$60	\$55	\$50	\$45	\$50
\$18.50	\$28	\$35.50	\$35.50	\$36	\$51.50	\$48.50	\$47

It will be noted that these firms do not agree very closely as to prices prior to the year 1900. The American Diamond Rock Drill Co., of New York, quoted \$52 per carat for best selected carbons and \$16 per carat for best selected boris in November, 1902.

There is no import duty on carbons in the United States, Canada or Mexico.

Water Required.—In boring a 2-in. hole where the progress is about 10 ft. per 10-hr. shift, from 100 to 125 gals. of water are required to wash out the sludge formed in drilling, provided the water is used but once. In cases where the water is expensive it is customary to collect the return water in a settling tank and use it over and over; and, unless a large amount of water escapes through crevices, 30 or 40 gals. per shift will be consumed by evaporation and leakage.

Price of Diamond Drills.—A hand power drill that can be used to bore a 1 1/8-in. hole (giving a 15-16-in. core) up to a depth of 350 ft.; or a 2 1/8-in. hole (giving a 2-in. core) up to a depth of 250 ft., will cost approximately \$850 f. o. b. New York or Chicago. This includes 300 ft. of pipe, 6 carats of carbons, all tools, etc., necessary. The machine alone weighs 330 lbs., and can be divided into packages weighing 40 lbs.; but the whole outfit packed for shipment weighs 2,800 lbs. If it is desired to run this drill by horse power, \$60 additional will purchase the horse power equipment. A hand power plant capable of drilling 50 per cent deeper than the above costs about \$1,400.

A steam power plant that can be used to bore a 1½-in. hole 800 ft. deep, or a 2½-in. hole (2-in. core) 600 ft. deep, costs about \$2,400, including the 8 hp. boiler on wheels; the drill itself costing \$1,100, the boiler \$400; 1 set of carbons (9 carats), \$450, and the balance for sundries. The drill itself weighs 600 lbs., but the full outfit packed for shipping weighs 10,000 lbs.

A steam power plant that can be used to bore a 1½-in. hole 1,500 feet, or a 2½-in. hole 1,000 feet, can be purchased for \$4,600; of which \$2,400 is for the drill, \$500 for the 15 hp. boiler on wheels, \$600 for 12 carats of carbons and the balance for rods and sundries. This outfit weighs 20,000 lbs.

Cost of Diamond Drilling in Virginia.—There is a great deal to be found in print relative to the cost of diamond drilling, but unfortunately the records as published are in such form as to be of far less value than they should be. By this I mean that any record of any kind of drilling to be of great value should give: (1) The rate of penetrating a given kind of rock when the drill is actually cutting; (2) the speed, power and weight of the machine; (3) the time lost in raising the drill to change bits, remove cores, or the like; (4) the time required to shift from one hole to the next; (5) the average time lost in repairs, breakdowns, etc.; (6) the diameter and depth of hole; (7) the time consumed in driving and pulling casing. No record in print contains all these factors. Strangely enough, one of the earliest printed accounts contains more of these factors than any subsequent record. I refer to an admirable paper by O. J. Heinrich, in *Trans. Am. Inst. Min. Eng.*, 1874, from which I have abstracted the following:

The diamond drill crew consisted of three men, two to run the drill and one to help raise the drill rods, beside a foreman. The shift was 12 hrs. long, and the following was the cost of operating a shift:

Foreman, or boring master	\$2.50
Mechanic, or engineer	2.00
Assistant	1.50
Laborer	1.00
Total labor	\$7.00

The coal consumed was 10 lbs. per hp. per hr. For holes up to 1,000 ft. deep an 8-hp. engine was used, the drill rods weighing 4,500 lbs.; but up to a 1,500-ft. hole a 12 hp. engine was used, with rods weighing 7,000 lbs. The drill had a 2-in. bit, on which were mounted never less than 12 carbons, better 16. The drill rods were raised after every 14 ft. of drilling. The drilling was done in Chesterfield county, Va., prospecting for coal, in 1873. The cost of operating per shift is given as follows:

Labor	\$ 4.50
½ ton coal at \$3.....	1.00
Oil	0.60
Diamonds and repairs	11.00
Interest and depreciation	1.92
Total per day	\$20.92

The price of carbons was \$10 per kt. Rates of wages were also much lower then, and it should be noted that the allowance for interest and depreciation is too low for a plant costing \$7,200, as it is stated this 8 hp. plant cost.

Depth of hole in earth and rock.....	412	\$50	1,142
Depth bored in rock	326	\$26	1,118
No. of 12-hr. shifts actually boring.....	13.88	44.41	59.29
No. of 12-hr. shifts raising rods.....	15.87	53.84	116.46
No. of 12-hr. shifts incidentals.....	3.25	15.35	68.25
No. of 12-hr. shifts total.....	23.00	119.00	224.00
Ft. progress per hr. while boring.....	2.37	1.55	1.57*
Ft. progress per hr., average.....	0.708	0.578	0.308
Cost of labor, per ft.	\$0.26	\$0.59	\$1.02
Cost of fuel (\$3 ton) per ft.....	\$0.52	\$0.14	\$0.17
Cost of all other items, incl. materials and blacksmithing	\$1.29	\$1.43	\$2.05
Interest	\$0.16	\$0.27	\$0.38
Total cost per ft.....	\$1.86	\$2.43	\$3.62

From the data given by Mr. Heinrich I have prepared the following formulas to be used in computing the number of hours required to drill a hole of given depth.

Let

T = Total number of minutes required to bore the hole.

n = total depth of hole in feet.

l = length of each coupling rod = 10 ft. in this case.

t = the number of minutes required to bore 1 ft. of the hole. In the formation given by Heinrich $t = 19$ mins. per ft. of hole up to a depth of 300 ft., to which add 5 mins. per ft. for each 100 ft. of increased depth.

r = time in minutes required to raise and lower the rods including 2 mins. to uncouple and couple up.

$r = 7$ mins. for hole up to 300 ft plus $\frac{1}{2}$ min. for each additional 100 ft.

s = number of lengths of coupling rod.

The time consumed in actual boring in feet is obviously nt . The time consumed in raising and lowering the drill rods is the sum of an arithmetical series in which s = the number of terms and r = the common difference; hence the sum is $\frac{1}{2}s(2r + [s-1])r$,

$$\frac{s(1+s)r}{2}$$

which reduces to $\frac{s(1+s)r}{2}$. The total time is therefore:

$$T = nt + s \frac{(1+s)}{2} r$$

$$s = \frac{n}{l}$$

$$T = nt + \frac{n(1+n)}{2l} r$$

If $l = 10$

$$T = nt + \frac{n(10+n)}{200} r$$

$$T = nt + \frac{n^2 r}{200}, \text{ nearly.}$$

For holes of the following depths we have

	Ft.	Ft.	Ft.
n	400	800	1,200
t (minutes) =	34	44	64
r (minutes) =	$7\frac{1}{3}$	$8\frac{2}{3}$	10
T (minutes) =	14,800	62,000	142,800
T (hours) =	240	1,050	2,480

On Heinrich's work about 10% more time than the above was required to cover losses from delays arising from various causes. The point that is strikingly brought out by Heinrich's records is the rapid falling off in the rate of speed of drilling each foot of hole with increased depth. The cause is obvious, however, for the longer the line of drill rods the greater the friction of the rods upon the sides of the drill hole, and consequently the slower their revolution with an engine of limited horse power. The increased weight of the rods with increased depth also reduced the rate of speed with which they are hoisted by the engine; and this is a very important factor in adding to the labor and fuel cost of drilling deep holes. Heinrich's estimates of the time required to drill holes, including all 10% allowances for delays, are as follows:

400-ft. hole	238 hours
800-ft. hole	980 hours
1,200-ft. hole	2,616 hours

It will be observed that these times check fairly well with the times obtained by applying the formula that I have given; but it should be added that the constants in the formula need further verification by other observers. The material penetrated in the 800-ft. hole was:

Hard silicious sandstone	210 ft.
Medium silicious sandstone	262 ft.
Argillaceous sandstone and slate.....	237 ft.
Limestone	15 ft.

Total827 ft.

Heinrich's estimates of time, and my own formula based thereon, assume a uniform sandstone throughout in the three holes. Had the rock been uniform throughout, the cost would have been:

400-ft. hole, at \$1.26.....	\$ 504
800-ft. hole, at 2.10.....	1,680
1,200-ft. hole, at 4.00.....	4,800

Cost of Diamond Drilling in Lehigh Valley.—Mr. L. A. Riley is authority for the following work done in 1876: Two machines belonging to the Lehigh Valley Coal Co. were used. A No. 2 drill with 16 hp. boiler and 1,000 ft. of 2-in. rod cost \$3,000, which with diamonds, etc., came to \$5,000; the weight being 2,500 lbs. Carbons cost \$9 per carat, and berts cost \$11. Five diamonds weighing 18 carats were used per bit, drilling a 2-in. hole and bringing up a $1\frac{1}{2}$ -in. core. There were 24 holes, aggregating 9,902 ft., the deepest being 800 ft. The average rate of drilling these holes was 19 ft. per day per machine, at an average cost of \$2.22 per ft. The rock was a very hard sandstone and conglomerate. The force on each drill was one foreman, one engineer and one fireman. The average cost per ft. of hole was:

Labor	\$1.15
Diamonds66
Supplies and repairs41

Total\$2.22

The cost of the 900-ft. hole (the deepest) was \$1.95 per ft., which indicates that with a powerful (16 hp.) engine there is no such great increase in cost per ft. with increased depth as Heinrich found with an 8 hp. engine. The 16-hp. plant used by Riley was capable of drilling a 2,000-ft. hole. Note especially that both Riley and Heinrich paid less than \$10 a carat for carbons and that Riley does not say what proportion of carbons to borts were used.

Cost of Diamond Drilling on Croton Aqueduct.—Mr. J. P. Carson, gives the following:

Fourteen holes, total, 2,084 ft., were drilled in the year 1896.

Actual days worked	189 days
Moving drill	15 days
Idle	18 days
Holidays and Sundays	39 days

Total261 days

	Daily progress Feet.	Cost per ft.
347 ft. hard gneiss.....	11 to 13	\$3.97
814 ft. decomposed gneiss.....	23.1 to 28	1.15
572 ft. clay, gravel and boulders.....	6.7 to 9	4.07
251 ft. clay and gravel.....	25
2,084 ft. Average.....	10.2	\$2.91

Crew, 1 foreman at \$125 mo.; 1 assistant foreman at \$70; 4 men at \$65.

Wages, 3.1 mos.	\$3,785
Team moving	80
66.7 tons coal (189 days)	360
Supplies, Diamond Drill Co.	472
Foundry	291
Lumber, rope, etc.	53
Interest on \$6,000 plant at 12% 3.1 mos.	486
Renewing diamonds	250
Diamond bit lost	300

Total, 204 days	\$6,077
Average per day	\$29.79
Average per ft.	\$ 2.91

Note that the item of interest is evidently intended to include depreciation, but, if so, it is altogether too low.

Cost of Hand Diamond Drilling in Arizona.—Mr. J. B. Lippincott gives the following data on diamond drilling at the Gila River Dam site, Arizona, in 1899. The machinery was in two distinct parts, (1) the hand pile driver for sinking casing pipe to bed rock; (2) the diamond drill. The hammer, made by the Pierce Well Co., 120 Liberty street, New York, is in sections, so that its weight can be varied up to 190 pounds; it is raised by a hand winch, and tripped by nippers; maximum drop 11½ ft. A tool-steel head is screwed into the top of the pipe and receives the blow. The pipe is 3½, 2½ and 2 in., extra heavy, screw pipe, 5 ft. sections, with extra heavy couplings, which have beveled edges. When the casing has reached bed rock, the sand inside is removed by using a chopping

bit and a water jet. The bit is screwed to a $\frac{3}{4}$ -in. pipe through which water is pumped by a hand pump, the water passing out through holes in the bit, thus bringing the sand to the top of the casing. In this manner a casing pipe 130 ft. deep can be cleaned of sand and gravel. If a boulder is struck, after the diamond drill has penetrated it, four or five sticks of dynamite are lowered and discharged, shattering the boulder so that the casing can be driven down.

The diamond drill was made by the American Diamond Rock Drill Co., New York City. One inch core bits were usually employed. The drill was operated by hand power, six men being employed on this work as well as on driving the casing. The drill will penetrate 200 ft. into rock, and will make 6 to 8 ft. per day in hard rock and 10 to 15 ft. per day in soft rock. The plant complete costs \$1,000, including two diamond bits worth \$200 each, set with six 1-carat diamonds each. Two machines were used. The pipe cost \$600 and freight, \$100.

Cost of operation per month, foreman.....	\$150	
6 laborers at \$1.50 for 28 days.....	234	
1 cook	45	
	\$	429
240 rations at 60 cts.....		144
Total labor for one month		\$573
Total repairs, pipe and lumber for one party for 10 months..	\$	500
Team, feed, etc.		350
Moving		670
Sundry incidentals		430
Supervision		350
Total supplies, etc., for 10 mos.....		\$2,300
Total labor, 10 mos.....		5,730
Total		\$8,030
Total number of feet sunk.....		3,254
Cost per ft.		\$ 2.46
52 holes, cost per hole		\$154.42

	Total Depths Penetrated.		
	Earth, ft.	Rock, ft.	Total, ft.
The Buttes	1,521.2	196.0	1,817.2
Queen Creek	357.8	55.6	413.4
Riverside	729.8	40.2	770.0
Dykes	80.0	0.0	80.0
San Carlos	143.2	30.4	173.6
	2,922.0	322.2	3,254.2

A month's time of one party was lost due to continual breaking of the casing pipe under the hammer. Note that 90% of the drilling did not involve the use of diamonds but consisted in driving through the earth covering overlying the rock. This is characteristic, however, of testing dam sites.

Cost of Diamond Drilling in Pennsylvania.*—Mr. E. E. White is author of the following:

**Engineering-Contracting*, Apr. 21, 1909, reprinted from "Engineering and Mining Journal."

The following notes on progress and cost of drilling in the coal measures of Greene county, Pa., were taken from April 20, to July 11, 1908. I was on the ground practically all of the time, representing the company who had optioned the coal, and so had a chance to obtain correct figures on the progress of drilling. The costs are not as accurate, but are essentially correct.

The cost of superintendence and carbons is estimated. The superintendent, C. C. Hoover, of the Birdsboro Steel Foundry & Machine Co., which concern took the contract for drilling, was on the ground only one day. As he was looking after about half a dozen other drills, the estimated cost for superintendence is liberal. The cost for carbons would have been much less but for the fact that $2\frac{1}{4}$ carats were broken at a depth of 21 ft. in the first hole, probably by a piece of steel in the hole. This bore was abandoned and another started 2 ft. away.

The drill only worked a day shift, and was run by two men, the drillman, H. N. Wighamman, and a fireman. Bits were set in the company's shop, not in the field. The hours in the progress table refer to the drill, that is, to two men, except in the case of hours setting bits.

The drill had a hydraulic feed and a double-core barrel, taking a $2\frac{1}{2}$ -in. core. The outfit, with one good diamond bit, is furnished by the Birdsboro Steel Foundry & Machine Co., of Birdsboro, Pa., for about \$3,500.

Considerable trouble was experienced with the boiler on the first two holes, which was accountable for a large part of the hours' delay on these holes, shown by the progress table. The boiler was of the upright type, set behind the machine on the heavy wagon frame. There were no stay bolts, and the flues frequently had to be rolled every three or four days after the first week, and finally were rolled every day for three days in succession. After stay bolts were put in, the flues were not rolled again on the job. Except for the boiler and a troublesome donkey pump which supplied the water tank, the outfit was excellent. The delay on the last hole was mostly waiting for water, which had to be pumped a little over a quarter of a mile.

The expense of pumping on the last hole is not included, as it was borne by the owners of the coal. The contract read that water should be furnished within 100 ft. of each hole. The cost of moving on and off the ground is not included, as it would be variable, according to the distance and means of transportation. The distance moved between holes averaged about a mile by road. It was open country with good roads, so that moving was not expensive.

The core obtained was practically complete, both of rock and coal. The surface was from 6 to 19 ft. deep, averaging 9 ft. 9 ins. It was clay, with no boulders, and was drilled out with a mud bit.

The table showing rates of drilling in different kinds of rock is the average of many observations on the five holes. The rate is.

of course, dependant largely upon the drillman and how much pressure he cares to put upon the bit.

Both cost and progress tables are from the time the drill reached the ground until ready to leave:

BITS USED.		Estimated Carbon Wear.
	Distance Drilled.	
Mud-bit	48 ft. 7 in.	
Diamond bit No. 1 (carbons broken by steel?)		2 1/4 carats
Diamond bit No. 2 (hole No. 1)	369 ft. 8 in.	1 1/2 carat
Diamond bit No. 3 (hole No. 2)	339 ft. 0 in.	1 1/2 carat
Diamond bit No. 4 (holes Nos. 3, 4) ..	500 ft. 1 in.	1 1/2 carat
Diamond bit No. 5 (hole No. 5)	562 ft. 8 in.	1 1/2 carat
	1,820 ft. 0 in.	4 1/4 carats

RATE OF BORING.		Ft. per Hour Actual Cutting.
Kind of Rock.		
Shale		7.05
Fire clay		7.10
Limestone		7.20
Sandstone		9.35
Coal		15.15

COST TABLE.		
	Cost.	Cost per ft.
Drillman	\$ 207.70	\$0.169
Fireman	192.31	0.106
Blank bits	5.00	0.003
Setting bits	10.00	0.005
Carbons (4 1/4 carats, at \$90)	382.50	0.210
Fuel (1,050 bus. coal)	67.17	0.037
Oil and waste	11.00	0.006
Repairs	24.85	0.014
Moving	36.00	0.020
Superintendence	200.00	0.110
Total working cost	\$1,226.53	\$0.680
Depreciation of outfit (20% on \$2,000 for 3 mos.)*	100.00	0.055
Total costs exclusive of freight and hauling on drill and wages and expenses of drillmen to and from Greene county	\$1,326.53	\$0.735

*The outfit exclusive of the bit is worth about \$2,000.

Table XI shows the time and progress of drilling.

Mr. Hoover, of the Birdsboro Steel Foundry & Machine Co., makes the total cost \$1.13 per foot, but I think that figure must be rather high. Four holes put down by the same company in Raleigh county, West Virginia, are said to have cost \$2.90 per foot.

Consumption of Diamonds in Diamond Drilling, Tennessee.—The cost of carbons and borts consumed in boring 39 underground holes at the Burra Burra and London mines, Ducktown, Tenn., is shown in Table XII. The holes were drilled in 1907 with two Sullivan machines of the "S" type, and all but three holes, aggregating 284 ft.,

TABLE XI.—PROCESS OF DRILLING.

	Hole No. 1.	Hole No. 2.	Hole No. 3.	Hole No. 4.	Hole No. 5.	Totals and Averages.

*Excludes hours setting bits.

†Excludes 20 hours putting stay bolts in boiler.

TABLE XII.—ANALYSIS OF STONE CONSUMPTION.

Total	Feet Drilled. Vein.	Country.	Stones Consumed.	Cost per Carat.	Total Cost.	Consumed per Foot.	Cost per Foot.
1,437	111	1,026	25 55/64k.	Borts at \$10.....	\$258.60	1.151 — 64	\$0.18
546	65	481	16 17/64k.	[Borts, 7 13/64 at \$10..... Borts, 9 4/64 at \$15.....]	72.03 135.94	1.304 — 64	0.3809
793	326	572	14 45/64k.	Borts at \$16	229.55	1.179 — 64	0.2764
167	80	77	3 30/64k.	[Borts, 6 42/64 at \$15..... Carbons, 1 52/64 at \$86.....]	98.34 154.06	2.246 — 64	0.9225
340	223	612	5 2/64k.	Carbons at \$85.....	427.66	0.382 — 64	0.5090
3,788	1,020	2,768	70 4/64k.	Totals and averages.....	\$1,363.68	1.184 — 64	\$0.3613

were horizontal across the formation. The core was 15/16 in. diameter and the holes 1 1/4 ins. in diameter.

The highest cost per foot was \$3.66, in a horizontal hole started in the footwall and drilled to a depth of only 8 ft., consuming 1.61/64 k. of \$15 borts. Excepting this hole, which penetrated very hard blue quartz, the highest cost for a hole drilled with borts was \$0.8838 per ft. This hole was drilled in the footwall of the Burra Burra mine to a depth of 52 ft., 27 ft. being in hard silicious vein material and 15 ft. in country rock; 2.57/64 k. of \$15 borts were consumed in boring it.

The lowest cost per foot was \$0.0921, and was obtained from a horizontal hole bored to a depth of 190 ft. in the hanging wall of the Burra Burra mine. This hole penetrated 10 ft. of vein material at its mouth, and the remainder cut through soft mica schist so thinly foliated that there were but few pieces of core recovered more than 1/2 in. thick. The stone consumption was only 29/64 k. of \$10 borts.

Cost Using Carbons.—The highest cost of a hole drilled with carbons was \$1.155 per ft. This hole was drilled in the footwall of the London mine to a depth of 9 ft. and penetrated 22 ft. of vein and 70 ft. of country rock. The loss in stones was 1 1/4 k. at \$85. The lowest cost with carbons was \$0.0718 per ft., from a hole in the footwall of the London mine which penetrated 30 ft. of vein and 44 ft. of country rock. The stone consumption for the hole was 1/16 k., at \$85.

Cost Using Borts.—The stone consumption given in the tables does not take into account the loss from scrap borts in the drilling. This loss was: 4.58/64 k. at \$15, \$73.59; 5.57/64 k. at \$10, \$58.90; total, 10.51/64 k., \$122.49. The above amount distributed to the 2,948 ft. drilled wholly and in part with borts gives an additional cost of about 4 1/4 cts. per ft. for holes drilled with these stones. There was no loss in carbon scrap, this loss occurring usually when the stones have worn too small to be utilized in a bit.

Summarizing and leaving out of the calculations those holes where both borts and carbons were used, the costs with borts were for 2,721 ft. drilled, \$687.12, or the cost per foot, \$0.247. The additional loss for scrap, which amounted to \$0.045 per ft., brings the cost up to \$0.292 per ft. This is considerably less than the carbon cost of \$0.5090, given in the table.

Adaptability of Each Stone.—Borts may be profitably used in drilling soft ground, but in hard material they are useless, as the stones, all of which contain flaws, will shatter when encountering hard rock. It is doubtful if borts could have been used with cheaper results in drilling the 840 ft. that were drilled with carbons. Some of this ground they would not have cut without great waste. Where part carbon and part borts were used, the carbons were substituted for the borts when it was found that the borts would not stand the work.

In some formations, where there are strata or zones of varying degrees of hardness, bits set with carbons might alternately be

used with those set with berts, but the bits could not very well be set in advance owing to the varying gage of the hole.

Cost of Diamond Drilling in British Columbia.*—Mr. Frederick Kaffer is author of the following:

Two years ago I contributed to the Institute a paper on the results of diamond drilling as carried on at the mines of the British Columbia Copper Company, Limited during 1905. That paper gave some details as to costs, and the period covered was but 8½ months. Since that year drilling has been carried on more or less continuously in the mines of the company, and the results of this work, so far as progress and costs are concerned, are given in detail in the following tables.

Table XIII gives the monthly results of work as well as the yearly totals. It is, of course, important to know the general character of the rock drilled in order to institute comparisons with other localities. In the narrow limits of this table it is not possible to give details as to rocks, but as nearly as possible the rocks comprise diorites, compact garnetites and certain very hard and silicious eruptives occurring in Summit camp. The medium hard rocks include all ores, and, in Deadwood camp, much of the greenstone country. The soft rocks are the limestones porphyries and serpentines. Of all rocks drilled the garnetites proved much the most severe in diamond consumption, as is illustrated by the work from May to August, 1907, which was mainly conducted in garnetite with some silicious limestones.

Eight hours constitute a shift underground, and nine hours on the surface. On Sundays no work is done apart from repairs to machinery. In May, 1906, the labor was contracted as an experiment, but was abandoned as being unsatisfactory.

The employees were, normally, a runner and a setter. Extra help was required at times for blasting places for good set ups, for laying pipe lines, moving plant, etc. In August, 1907, two shifts were employed. In June and July of that year the increase in labor costs is mainly on account of the long pipe lines required.

The power consumed is taken as being equivalent to that required for a 3¼-in. machine drill, that is to say, about 20 hp. When drilling at a mine, where for example 15 machines are used on each shift, the diamond drill is charged with 1/31 of the total power costs—it being in this instance run on one shift only.

Where steam power is used either directly or through a steam driven air compressor, the costs are much increased. Where, as in some cases, an isolated 24-hp. boiler was used, the power costs are still higher, as an engineer has to be provided as well as a team to haul wood.

Tools, repairs, etc., include these items as well as all small miscellaneous expenses. The increasing cost of diamonds (\$80 per

**Engineering-Contracting*, May 6, 1908; abstract of a paper before the Canadian Mining Institute, with additional data furnished by the author.

TABLE XIII.—PROGRESS TABLE.

Date	Depth of holes, feet.	Hours actual drilling.	Hours moving, setting, etc.	Total hours	No. of holes	Carats used	Yds. per drill.	Character of Rock.

^aThis month's work was contracted as to the labor. Feet drilled are therefore not included in averages as contractor worked overtime.

¹Hard rocks.

²Medium hard rocks.

³Soft rocks.

⁴Averages calculated on 3,002 ft. less 483 drilled on contract.

⁵Several days lost moving 15 miles to another mine.

⁶Much trouble with caving ground in August. Worked two shifts nearly all the month.

⁷Of these 3,002 ft., there were 1,523 ft. vertical and 1,479 ft. horizontal.

⁸Of these 3,667 ft., there were 1,573 ft. vertical and 2,094 ft. horizontal.

carat in 1907 as compared with \$60 in 1906) added materially to cost per foot in 1907.

The carats used per foot were 0.572/64, or in more intelligible decimals, .00893 carats, so that one carat on the average drilled 111.9 ft. All holes over 30 degrees dip are classed as vertical, and ft. per hr. in horizontal holes is about 15% greater than in vertical ones. The average depth of holes is 81.3 ft., and diameter of cores is 15/16 in.

In comparing these costs with contractors' prices, it must be borne in mind that contractors usually require air (or steam) and water to be piped to the work, and the mine must in addition furnish the air and water free of charge. In the present cost sheets all these items are charged against costs of drilling.

The drill runner set and was responsible for the diamonds. He was paid a salary of \$175 per month, while two helpers, during the period of time given, received \$3.50 per day. Since the decline in the price of copper, helpers are only paid \$3.30 per shift. The compressor men receive \$4 per day.

Wood for fuel costs \$3.50 to \$5 per cord, according to locality. Electric power costs \$33 to \$40 per hp. per year.

The drilling was done with a "Beauty Drill," of the Bullock type, made by the Sullivan Mchy. Co., of Chicago. The machine has been in service three years and is in excellent condition. The catalog price of the drill is \$1,500, with its equipment, including 2 bits ready for carbons, but not including carbons. The shipping weight is 1,160 lbs. It will drill to a depth of 800 ft., making a hole 19/16 in. diam. and giving 15/16 in. core.

The following were the unit costs in 1906 and in 1907, also in March, 1907, when the lowest unit cost was secured:

Cost in 1906 (3,002 Ft. Drilled).

	Per lin. ft.
Labor	\$0.786
Power	0.205
Repairs, oil, etc.....	0.109
Carats (28 56/64, cost \$1,728).....	0.576
Total	\$1.676

Cost in 1907 (3,667 Ft. Drilled).

	Per lin. ft.
Labor	\$0.715
Power	0.280
Repairs, oil, etc.....	0.100
Carats (30 47/64, cost \$2,828).....	0.633
Total	\$1.728

Cost in March, 1907 (540 Ft. Drilled).

	Per lin. ft.
Labor	\$0.492
Power	0.099
Repairs, etc.	0.049
Carats (2 37/64, cost \$219).....	0.405
Total	\$1.045

Mr. Keffer estimates 16% per year will cover the interest and de-

preciation, or \$240 per year to be added to the costs above given, or about 8 cts. per lin. ft. of hole when 3,000 ft. are drilled per year.

Costs of Calyx Core and Diamond Drill Borings, Nova Scotia.*—To further the interests of the mining industry in Nova Scotia the Department of Mines of that province has since 1900 owned and operated a number of core drills for prospecting purposes. In the report of the department for 1908 there are given a summary of the depths of holes bored and the cost of the work for each year from 1900 to 1908, inclusive, and also the itemized cost of the work done during 1908. The following data are compiled from these records.

During 1908 the department had 5 drills in operation, 2 of the Sullivan diamond pattern and 3 of the Calyx shot type. The work of these drills is given as follows:

Drill No. 5.—This was a steam Calyx drill, producing a 6-in. core; its work comprised two holes in the Cape Breton coal measures, one 769½ ft. deep and one 1,170 ft. 11 ins. deep.

The first hole, 769½ ft. deep, was through sandstone, shale and coal. Work was begun Jan. 15, 1908, and the hole was finished March 21, 1908. The average rate of drilling was 0.6 ft. of hole per hour; the maximum rate was 3 ft. of hole per hour. The boring was done with a double shift. The cost of the hole was as follows.

Item.	Total.	Per ft.
Labor including truckage.....	\$ 864	\$0.862
Management	241	0.213
Coal	171	0.222
Light, oil, waste, etc.	7	0.009
Shot	56	0.072
Gravel	3	0.004
Lumber, etc.	30	0.040
Casing pipe	5	0.006
Totals	\$1,177	\$1.528

The second hole, 1,170 ft. 11 ins. deep, was, like the first, through sandstone, shale and coal. Work was begun March 30, 1908, and the hole was finished July 11, 1908. The average rate of drilling was 0.58 ft. per hour and the maximum rate was 3 ft. per hour through sandstone. The boring was done with a double shift. The cost of the hole was as follows:

Item.	Total.	Per ft.
Labor including truckage.....	\$ 995	\$0.849
Management	331	0.282
Coal	200	0.171
Light, oil, waste, etc.	8	0.007
Shot	68	0.058
Gravel	5	0.004
Lumber	15	0.013
Casing pipe	14	0.012
Short bits and core barrels.....	168	0.143
Totals	\$1,804	\$1.539

Drill No. 2.—This was a steam diamond drill, producing a

**Engineering-Contracting*, July 28, 1909.

15/16-in. core; its work comprised 6 holes in the Nova Scotia coal measure, 1 at Merigomish, Pictou County, and 5 near New Glasgow.

At Merigomish the hole was through red and gray sandstone and shale and was 536 ft. deep. Work was commenced Sept. 13 and the hole was finished Oct. 20, 1907. The average rate of drilling was 1.46 ft. per hour, and the maximum rate was 4 ft. 8 ins. per hour in gray sandstone. The boring was done with a single shift. The cost of the hole was as follows:

Item.	Total.	Per ft.
Labor, including freight and truckage..\$	132	\$0.248
Management	246	0.457
Fuel	11	0.021
Light, oil, waste, etc.....	1	0.002
Carbon wear	5	0.009
Lumber	2	0.004
Core lifters and bits	18	0.024
Totals	\$410	\$0.765

Details of the drilling of only 4 of the holes sunk at New Glasgow are given. The rock penetrated was gray sandstone and shale and black shale, with frequent hard bands.

Hole No. 1, 909 ft. deep, was begun Dec. 9, 1907, and finished Feb. 14, 1908, boring single shift. The average rate of drilling was 1.4 ft. per hour and the maximum rate was 5 ft. in one hour in hard gray sandstone. The cost of the hole was as follows:

Item.	Total.	Per ft.
Labor, including freight	\$131	\$0.144
Management	226	0.369
Coal	36	0.040
Light, oil, waste, etc.....	6	0.007
Carbon wear	2	0.002
Lumber	17	0.019
Casing, pump, pipe, etc.....	22	0.026
Core lifters and bits.....	21	0.022
Totals	\$582	\$0.640

Hole No. 2, 842 ft. deep, was begun March 4 and finished May 30, 1908, working single shift. The average rate of drilling was 1.2 ft. per hour and the maximum rate was 3 ft. 6 ins. per hour in gray shale. The cost of the hole was as follows:

Item.	Total.	Per ft.
Labor, including freight.....	\$130	\$0.154
Management	264	0.431
Fuel	30	0.036
Light, oil, waste, etc.....	56	0.065
Steel shot.....	4	0.004
Blank bits, core lifters, shells, etc.....	32	0.038
Repairs to engine	20	0.023
Totals	\$635	\$0.751

Hole No. 3, 646 ft. deep, was begun June 11 and finished Aug. 4, 1908, working a single shift. The average rate of drilling was

ROCK EXCAVATION, QUARRYING, ETC. 245

1.4 ft. per hour and the maximum rate was 5 ft. per hour in coal. The cost of the hole was as follows:

Item	Total	Per ft.
Labor	\$ 89	\$0.124
Management	249	0.385
Fuel	21	0.032
Oil, waste, etc.....	9	0.014
Carbon wear	20	0.031
Core lifters, bits, core shells.....	13	0.020
Totals	\$292	\$0.606

Hole No. 4, 500 ft. deep, was begun Aug. 11 and finished Sept. 19, 1908, working a single shift. The average rate of drilling was 1.5 ft. per hour and the maximum rate was 5 ft. in one hour in gray sandstone. The cost of the hole was as follows:

Item	Total	Per ft.
Labor, including truckage.....	\$ 67	\$0.134
Management	180	0.360
Fuel	15	0.030
Light, oil, waste, etc.....	4	0.008
Carbon wear	31	0.062
Black bits, core lifters, steel shoes.....	16	0.030
Totals	\$312	\$0.624

Drill No. 2.—This drill was a hand diamond drill, producing a 15/16-in. core, and its work consisted of boring 6 holes in sandstone, shale and limestone to develop a limestone suitable for the manufacture of cement. The holes were of the following depths:

No. 1	65 ft.	8 ins.
No. 2	30 ft.	1 in.
No. 3	31 ft.	0 ins.
No. 4	44 ft.	6 ins.
No. 5	36 ft.	8 ins.
No. 6	36 ft.	0 ins.
Total	243 ft.	11 ins.

The aggregate cost of the 6 holes was as follows:

Item	Total	Per ft.
Labor	\$219	\$0.857
Management	130	0.532
Freight and truckage.....	12	0.049
Casing pipe	16	0.068
Carbon wear	123	0.504
Totals	\$500	\$2.007

This same drill was employed to sink one hole in the coal measures, as follows: The hole was 134½ ft. deep, through shale and sandstone; work was begun July 22 and the hole was finished Aug. 12, 1908, working a single shift. The average rate of drilling was 0.74 ft. per hour and the maximum rate was 1 ft. 3 ins. in one hour. The cost of the hole was as follows:

Item	Total	Per ft.
Labor	\$107	\$0.798
Management	50	0.383
Light, oil, waste, etc.	0.55	0.004
Carbon wear	61	0.455
Freight, truckage, repairs, etc.....	36	0.267
Totals	\$254	\$1.887

Drill No. 5.—This drill was a steam Calyx drill, producing a 6-in. core. It was employed in putting down four holes in the Cape Breton coal measures, as follows:

Hole No. 1 was begun Feb. 27 and finished April 12, 1908, working double shift. The average rate of progress was $2\frac{1}{2}$ ft. per hour and the maximum rate was $5\frac{1}{2}$ ft. in one hour. The hole was 424½ ft. deep and its cost was as follows:

Item.	Total.	Per ft.
Labor, including freight and truckage...	\$294	\$0.691
Management	150	0.353
Coal	35	0.083
Light, oil, waste, etc.	6	0.014
Shot	18	0.042
Gravel	3	0.007
Lumber	45	0.106
Totals	\$551	\$1.296

Hole No. 2, 208½ ft. deep, was begun May 20 and was finished May 30, 1908. The average rate of drilling was 1 ft. per hour and the maximum rate was $5\frac{1}{2}$ ft. per hour. A double shift was worked. The cost of the hole was as follows:

Item.	Total.	Per ft.
Labor, including freight and truckage...	\$127	\$0.612
Management	33	0.158
Fuel	15	0.072
Light, oil, waste, etc.	2	0.009
Shot	10	0.048
Gravel	1	0.005
Lumber	12	0.058
Casing	5	0.024
Totals	\$205	\$0.986

Hole No. 3, 267 ft. deep, was begun June 4 and finished June 27, 1908, working double shift. The average rate of drifting was 0.9 ft. per hour and the maximum rate was 8 ft. in one hour with cutters. The cost of the hole was as follows:

Item.	Total.	Per ft.
Labor, including freight and truckage...	\$272	\$0.741
Management	75	0.204
Fuel	21	0.067
Light, oil, waste, etc.	5	0.013
Shot	27	0.073
Lumber	8	0.022
Shot bits	7	0.019
Totals	\$415	\$1.120

Hole No. 4, 502 ft. deep, was begun on July 8 and was finished on July 29, 1908, working double shift. The average rate of drilling was 1.2 ft. per hour and the maximum rate was 8 ft. in one hour with shot. The cost of the hole was as follows:

Item.	Total.	Per ft.
Labor, including truckage.....	\$251	\$0.500
Management	72	0.143
Fuel	22	0.043
Light, oil, waste, etc.	4	0.008
Shot	15	0.029
Lumber	7	0.013
Pumping water	80	0.159
Shot barrels used.....	16	0.029
Totals	\$466	\$0.924

In presenting these results we have computed and added the columns of costs per foot drilled. The report says:

The average cost per foot for boring by drills was \$1.04. The cost per foot for all boring by diamond drills was 80½ cents, and by Calyx drills \$1.34. The carbon cost per foot in boring by diamond drills was \$0.077, and the shot-cost per foot by Calyx drills, \$0.056. These costs compared with last year's results were as follows:

	1907.	1908.	Inc. or Dec.
Cost per foot for all boring.....	\$1.23	\$1.04	Dec. 17c
Cost per foot for all Calyx boring.....	1.71	1.34	Dec. 31c
Cost per foot for all diamond boring..	.73	.845	Inc. 11c
Shot-cost per foot boring by Calyx drills	.047	.056	Inc. .009c
Carbon cost per foot boring by diamond	.0129	.077	Inc. .041c

Cost of Core Drilling With a Well Driller.*—In this article we give the cost of drilling holes through rock with a well-drilling machine. Holes Nos. 1 and 2 were holes from which cores were taken, being put down through limestone at Paris, Ky., for the Blue Grass Mining and Development Co. For these two holes a Cyclone steam four-core drill, class E 1, was used, taking a 3¼-in. core. This drill will take cores of 2¼, 3¼ and 4¼ ins., to a depth of 300 ft. It is the lightest four-core drill made by the Cyclone Co., of Orrville, Ohio. Equipped ready for work, it is sold for less than \$1,000, but for our purpose of estimating depreciation and interest on the machine we will consider the price as \$1,000, as this figure will cover the freight and other incidental expenses of buying the machine. This machine can be operated by a drill runner and one assistant.

Hole No. 1.—This hole was entirely in limestone and was drilled to a depth of 104 ft. in 50 hrs. actual time of running the machine; the average rate of drilling per hour was 2 ft. 1 in. The men worked more than 50 hrs., the actual time they worked being charged against the hole. The cost was:

Moving drill.....	\$ 3.50
Coal	4.85
Water	3.00
Driller, 50 hrs. @ \$0.50.....	30.00
Helper, 55 hrs. @ \$0.15.....	9.90
Supplies, shot and bits.....	5.00
Depreciation, repairs and interest per day assumed at \$1.50.....	9.00
	<hr/> \$64.25

This gives a cost per lineal foot of hole for each item as follows:

Moving drill.....	\$0.03
Coal05
Water03
Labor38
Supplies05
Depreciation, repairs and interest.....	.08
Total	<hr/> \$0.62

Hole No. 2.—This hole was 158 ft. through limestone, 80 hrs.

*Engineering-Contracting, Sept. 9, 1908.

being consumed in drilling it. This meant a rate per hour of about 2 ft. The total cost of the hole was as follows:

Moving drill.....	\$ 3.75
Coal	6.00
Water	4.00
Supplies, shot and bits.....	10.00
Driller, 30 hrs. @ \$0.50.....	40.00
Helper, 32 hrs. @ \$0.15.....	13.20
Depreciation, repairs and interest, per day assumed at \$1.50.....	12.00

Total\$38.95

This gives a cost per lineal foot of hole for each item as follows:

Moving drill.....	\$0.03
Coal04
Water02
Labor34
Supplies06
Depreciation, repairs and interest.....	.08

Total\$0.57

Holes Nos. 4 and 5 were drilled with cable tools, a No. 4 Cyclone drill being used for putting down a 5-in. hole. The work was done near Arritts, Va., for the Low Moor Iron Co. The No. 4 drill is a standard well-drilling machine, and will sink a hole to a depth of 500 ft. It has an 8-hp. boiler and a 7-hp. engine, mounted on traction wheels, weighing in all over 6,000 lbs. This machine can also be rigged to take cores. Depreciation, repairs and interest on it per day will be about the same as for the other drill. Two men operate it.

Hole No. 3.—This hole was drilled through the following materials:

	Ft.
Clay	7
Shale	113
Cap rock (disintegrated).....	8
Sandstone	14

Total142

The time consumed in drilling this was 32 hrs., making a rate of 4 ft. 6 ins. per hour. The cost of the work was as follows:

Coal	\$ 4.00
Water	2.40
Driller, 40 hrs. @ \$0.20.....	8.00
Helper, 40 hrs. @ \$0.15.....	6.00
Depreciation, repairs and interest per day, assumed at \$1.50.....	6.00

Total\$26.40

This includes moving the machine. The cost per lineal ft. for each item was:

Coal	\$0.03
Water02
Labor10
Depreciation, repairs and interest.....	.04

Total\$0.19

Hole No. 4.—This hole was 67 ft. deep, being drilled through the following materials:

	Ft.
Shale	25
Cap rock	2
Ore	10
Sandstone	16
Flint	9
Total	67

Thirteen hours were consumed in drilling this hole, making a rate of progress of 5 ft. and 1 in. per hour. The cost of the work was:

Coal	\$ 1.00
Water30
Driller, 20 hrs. @ \$0.20	4.00
Helper, 20 hrs. @ \$0.15	3.00
Depreciation, repairs and interest, per day \$1.50	3.00
Total	\$11.30

This gives a detail cost per lineal foot of the following:

Coal	\$0.015
Water	0.005
Labor	0.100
Depreciation, repairs and interest	0.040
Total	\$0.160

All these holes, it will be noticed, were through soft rock, but the costs for the work are very reasonable.

Cost of Diamond Drill and Wash Borings Near New York City.—Mr. F. Lavis is author of the following.—The following costs of making diamond drill borings were obtained on work in New York City in the fall of 1905. The work was started in October and ran through to the early part of January, there being more or less delay during the latter part of the work (on the diamond borings) due to snow and ice.

The average depth of the holes was about 40 ft., partly in earth and partly in rock, the depth of the latter below the surface varying from 2 to 25 ft., and it being generally overlaid by more or less fine sand. A 2½-in. wrought iron pipe casing was sunk to the rock by a separate crew by the wash method and firmly seated thereon. A 1¼-in. core was obtained of the rock and samples of the washings were taken and preserved in glass jars. The rock was the ordinary New York gneiss and mica schist, which affords easy drilling where seams are not encountered which tend the drill off line and bind the bit.

The crew of the wash machine consisted of 1 foreman at \$3 per day and of 3 laborers at \$2 per day. A proportion of the superintendence, water supply, watchman, etc., was also charged to this part of the work. This crew sunk all the casings to the rock ready for the diamond machine, the work occupying about 15 working days.

**Engineering-Contracting*, Jan. 9, 1907.

Power for the diamond drill was furnished by a small upright boiler and much time was wasted in shifting the boiler and drill apparatus from one hole to another; had these been both mounted on wheels the expense for drilling would have been cut down at least 10 per cent and probably more. After the first two moves had been made an extra laborer (sometimes two) was put on during the time of moving at \$2 a day, with the result that the time was cut down half, from 12 to 16 hours' actual working time to 6 or 8.

A superintendent, who also set all the diamonds, devoted about half his time to the work and was paid \$100 per month, and \$100 per month rent was paid for the use of the diamond drilling machine. The boiler and wash boring outfit were on hand, having been used previously, and no cost is included for their use. The costs do include an allowance for all pipe used, cost of fuel and other materials and of repairs to diamond machine on completion of work, and new grate bars for the boiler.

The pay-roll was as follows:

1 Superintendent ($\frac{1}{2}$ time).....	\$100.00 per month
Rent of machine.....	100.00 per month
1 Foreman	3.50 per day
1 Rigger	2.25 per day
2 Laborers	2.20 per day
1 Night watchman.....	1.50 per day
1 Inspector of city water department.....	3.00 per day

Water was obtained from the city hydrants and cost about \$25 for permits, etc., besides the \$3 per day for the inspector.

The costs shown below are considered quite low (at least \$1 per ft. less than usual), this being due to a large extent to the very small abrasion of the diamonds. This latter is a most important matter and the favorable results in this case, the loss in some holes being as little as $\frac{1}{8}$ carat, and seldom over $\frac{1}{4}$, was due to the fact that stones were available which had been previously used (and therefore tested), and that the superintendent who set the stones was an expert at this work. With diamonds at \$60 per carat, the importance of properly selected stones, skilful setting and manipulation is apparent.

The following is a summary of the cost:

WASH BORINGS, 206.8 LIN. FT.

	Total.	Per lin. ft.
Labor	\$ 276.92	\$1.34
Engineering	35 00	0.17
Total	\$ 311.92	\$1.51

DIAMOND DRILL BORINGS, 460.9 LIN. FT.

	Total.	Per lin. ft.
Labor	\$1,888.73	\$4.09
Engineering	316 00	0.69
Total	\$2,203.73	\$4.78

DIAMOND DRILL AND WASH BORINGS, 667.7 LIN. FT.

	Total	lin. ft.
Labor	\$2,166.65	\$2.25
Engineering	350.00	0.52
Total	\$2,516.65	\$2.77

Rock Excavating Using Well Drills.*—Mr. R. M. Hulbert is author of the following.—The quarries of the Atlas Portland Cement Company at Northampton, Pa., are two in number and are situated close to the works of the company. No. 1 quarry is the nearest to the works and is 1,600 to 1,800 ft. long on the face. No. 2 quarry is at a distance of a mile or so from the works and is approximately 1,800 ft. long on the face. These faces range from 43 to 100 ft. in height.

The rock was formerly excavated by benches, i. e., steam or compressed air rock drills were used for drilling holes 20 ft. deep which were charged with dynamite and blasted. The dislodged rock was cleaned up by hand labor after which the drills were again set up and the process repeated. In this way the face of the quarry was removed by three benches, all material being carried away in standard gage freight cars running on tracks laid on the bottom bench, or floor of the quarry.

The drills used for this part of the work were ordinary compressed air rock drills capable of drilling holes 20 ft. in depth with a bottom diameter of $2\frac{1}{4}$ in. It was thought that by drilling holes below grade and blasting larger quantities of rock at a time, the cost of handling the excavated material would be materially reduced, all hand labor being practically eliminated and the rock removed by steam shovels running on railroad tracks on the floor of the quarry. It was therefore decided to introduce well drills for this work in place of the rock drills formerly used and the results achieved have more than warranted the change.

The character of the rock, however, makes the work of drilling with well drills of an exceedingly difficult nature as this limestone is not only hard and tough but is honeycombed with seams running at every conceivable angle. In spite of this handicap the drills are averaging approximately $1\frac{1}{2}$ ft. per hour taking into consideration all delays due to blasting, sharpening steels and for other purposes. There are seven drills actually engaged on the work and these are not only able to keep four steam shovels busy in the two quarries, but have drilled many holes ahead. As a general rule, however, it has been found that drilling holes ahead does not always pay as the magnitude of the blasts often throws some of the holes out of plumb and discretion has to be exercised in planning ahead on this part of the work. The drills were manufactured by the Star Drilling Machine Co. of Akron, Ohio.

It sometimes happens that well drilling machines cannot be used to advantage, and an instance of this is to be found in the case of quarry No. 2 of the Atlas plant. Here the entrance to the quarry consists of a narrow opening with high vertical faces on

*Engineering-Contracting, June 5, 1907.

each side. It would be obviously impracticable to widen this opening by means of heavy blasts as by so doing there would be danger of closing up the opening, it being a singular fact that in blasts of this character, the material at the base of the hole is blown outward to a considerable distance, while that at the top settles down vertically and is scarcely thrown out at all. In the case of quarry No. 2 of the Atlas plant, the narrow entrance is being widened by the bench method, eight compressed air rock drills being used. As soon as the face is moved back far enough, however, well drills will be substituted and the holes drilled to grade.

At both quarries the holes are drilled at a distance of 20 ft. from the face and approximately 18 ft. apart, it being the customary practice to space these holes by moving the machine a distance forward equal to its own length, which in this case is about 18 ft. In No. 1 quarry there are two well drilling machines, operating on compressed air and working in two shifts of 10 to 12 hrs. each. Besides these there are the eight compressed air rock drills engaged in opening up the entrance by the bench method. In No. 2 quarry there are five well drills operated by steam generated in a 185-hp. central boiler plant. The steam pressure is maintained at 110 lbs. except when blasting occurs, at which times it is lowered to 35 lbs., as it was found that the detonation of a heavy blast tended to "start" the tubes in the boiler if the pressure was not reduced. A 3-in. steam line leads from the boiler plant to the drills, but this line can also be used for compressed air if desired and, in fact, compressed air is used to operate the drills during the night shift. Of course, it is impossible to install a very high class steam plant for this work owing to the fact that there is no element of permanency in the installation. The plant has already been moved twice and will probably have to be moved again within the next twelve months. In spite of this fact, however, very good economy is obtained, care being taken to thoroughly lag the steam lines which are, in no case, more than 300 ft. in length.

The depth of holes in this quarry ranges from 45 to 35 ft., the diameter being 5 ins., and it is the usual practice where holes are only 45 ft. deep, to drill them with one bit, the wearing away of the gage being in about the right proportion to the depth of hole to do away with the need of changing steels. In the deeper holes, bits are changed at regular intervals until the last 35 ft. is reached when one bit is used to the bottom. As a general rule, however, it might be said that drills are sharpened every 10 ft.

The very difficult nature of the ground and the fact that frequent stops have to be made to straighten holes and during blasting, makes the average of $1\frac{1}{4}$ ft. per hour, taking into consideration all delays, a very good one. But it must be remembered that the real element of economy is not so much in the speed of drilling as in the greater efficiency in blasting, more rock being displaced by blasting holes drilled below grade than by successive lifts of 20 to 25 ft. In working in these benches each bench has to be cleaned off by hand labor, except the final one at grade which may be cleaned off by steam shovels.

Cost of An Artesian Well.*—Mr. Wm. G. Fargo, consulting engineer, of Jackson, Mich., has furnished us with the following data regarding the cost of an artesian well:

The well was sunk at the Lansing, Mich., sub-station of the Commonwealth Power Co. It was 3 ins. in diameter and 197 ft. deep. Of this depth 50 ft. was through soft material and 57 ft. through rock. This meant that only 50 ft. needed sheathing, which was done by 50 ft. of 3-in. pipe at a cost of 32 cts. per foot, making a total cost for pipe of \$16.

The well drilling machine, a small one, was hired for the work, 40 cts. per hour being paid for the use of the machine and the services of the man to run it. One laborer assisted this man in drilling the well. Record was not kept of the fuel used.

The cost was as follows:

71 hours' use of machine at \$0.60.....	\$42.60
69 hours' labor at \$0.20.....	13.80
50 ft. 3-in. pipe at \$0.32.....	16.00
Total	\$72.40

This gives a cost per lineal foot of well of \$7.6 cts.

For other data on the methods and costs of sinking wells see the index under "Well Drilling."

Cost of Drilling Limestone With Well Driller, For a Quarry.†—There has been some demand in large blasting work for a well drilling machine operated by electric power instead of by the usual boiler and engine. Where blasting operations are conducted within city limits some inconvenience and a large item of expense are represented in providing a licensed engineer, as required by law, for each separate steam driven machine. There is also economy in generating all power at a central plant. In some locations also it is impossible to use a boiler. To meet these difficulties some contractors have operated a number of drillers from one centrally located steam or compressed air plant, carrying pipes to the several machines. These last plans, however, involve the constant relaying of steam or air lines with bother and loss of power from condensations, leakage, etc. To obviate these and other disadvantages connected with the steam machine as used in certain classes of work, the Keystone Quarry Drill Co., Beaver Falls, Pa., has designed an electric driven machine and one of these has now been at work for some time in the Belleville, Ill., quarries of James & A. C. O'Laughlin, of Chicago, Ill. The following data relate to this machine and its work:

The machine is equipped with a 10-hp. specially geared motor placed over the rear truck and belted to the drilling mechanism, which is back geared and balanced so as to run lightly and smoothly. The controller box is located at the front of the machine close to the driller's hand. The drilling tools comprise a stem weighing about 1400 lbs., a drill bit weighing 150 lbs., and a rope socket weighing about 50 lbs., or about 1,200 lbs. together. The bit cuts a 5½-in.

*Engineering-Contracting, April 2, 1908.

†Engineering-Contracting, July 21, 1909.

hole and the stem is $3\frac{1}{4}$ ins. in diameter and 22 ft. long. As the stroke is from 20 to 26 ins., a blow of from 2,000 to 2,500 ft. lbs. is obtained at each stroke. The machine is built with gear hoist, capacity 500 ft., or with friction hoist, capacity 250 ft. The makers consider the latter style of machine probably the best for quarry and rock cut work where the tools are being constantly raised and lowered as in tamping a charge, and where the holes will rarely exceed 150 ft. in depth. This machine is made with a traction attachment for self propulsion if desired; while it is impracticable to move the machine over great distances by this means, on account of carrying along the electric feed wires, for short moves from hole to hole or from one side of the quarry to the other it has been found to be of great advantage.

In operating at the full speed of the motor the tools make about 60 strokes per minute. As the hole becomes deeper or clogged with cuttings, before sand pumping, the rapidity of the stroke is gradually reduced to say 50 strokes per minute in order that the cutting bit may deliver its blow with best effect. This change of speed is produced by reducing the speed of the motor.

Besides doing the drilling this machine is used for loading the holes. For this service the regular drilling bit is removed and in its place a wooden rammer is placed on the drill stem. From 5 to 8 sticks of dynamite having been dropped into the hole the drilling tool is lowered after them, forcing them to the bottom. The tools are then withdrawn and the operation repeated until all the charge is placed. The placing of the firing cap and wires and the tamping are done by hand.

At the James & A. C. O'Laughlin quarry limestone is being drilled and blasted for crushed stone. The machine was furnished by the makers on the guarantee to drill to a depth of 60 ft., at the rate of 40 ft. per 10-hour day, or 4 ft. per hour. In the tests made on delivery of the machine the following records were obtained: The machine was set up on June 5 at 5 o'clock and ran for 1 hour, drilling 9 ft. of hole. From the following Monday morning until Friday forenoon, something over 4 days, working 10 hours a day, four 66 ft. holes or 264 ft. of hole were drilled. In the following week four holes 105 ft. deep or 420 ft. of hole were drilled. These figures are furnished by the Keystone Quarry Drill Co. In a letter to us the James & A. C. O'Laughlin Co. state that in actual work the machine is averaging 40 ft. of $5\frac{1}{4}$ -in. hole per 10-hour day, and is giving good satisfaction. The daily operating expenses are as follows:

One drill runner at \$2.50.....	\$2.50
One helper at \$2.....	2.00
Cost of electric current.....	2.00
Oil, drill sharpening, etc.....	1.50
Total per day.....	<u>\$8.00</u>

This gives a cost per foot of hole drilled of 20 cts.

In a blast of four $5\frac{1}{4}$ -in. holes 66 ft. deep, the charge consisted of 2,500 lbs. of dynamite packed solidly in the holes to within 25 ft. of the top and then tamped with screenings. The quarry manager

estimated that 20,000 cu. yds. of stone were thrown down by this blast. The breast was 105 ft. high, and, as will be seen, the holes were put down only about half way. In recent work the holes have been drilled the full depth of the breast.

Cost of Drilling Rock With a Well Drilling Machine.*—The following is a record of some holes drilled, and the cost of drilling them, at Mussellshell and Roundup, Montana, for the Republic Coal Co. of Chicago, Ill.

The work was done with a No. 3 Cyclone drill, manufactured by the Cyclone Drill Co., of Orrville, Ohio. The machine was equipped with hollow rod tools. This machine is meant to drill holes from 500 to 700 ft. deep; it is equipped with a 7-hp. engine run with gasoline. Holes from 23 ft. to 517 ft. were drilled. The bits used were 2½ in. Two men, the drill runner and a helper, were employed on the machine. The work was done in prospecting. The record of each hole is given in the table.

RECORD OF HOLES DRILLED.

Hole No.	Depth.	Average drilled per shift.	Material.
1	391 ft. 7 in.	39 ft. 1 in.	Shale and sandstone.
2	293 ft.	26 ft. 7 in.	Shale and sandstone.
3	284 ft.	47 ft. 4 in.	Shale and sandstone.
4	347 ft.	49 ft. 7 in.	Shale and sandstone.
5	103 ft.	51 ft. 6 in.	Shale and sandstone.
6	297 ft.	42 ft. 5 in.	Shale and sandstone.
7	36 ft. 6 in.	52 ft.	Soil and gravel.
8	23 ft. 11 in.	32 ft.	Soil, gravel, shale.
9	51 ft. 8 in.	47 ft. 8 in.	Soil, gravel, shale.
10	27 ft. 3 in.	32 ft.	Soil, gravel, shale.
11	53 ft. 5 in.	30 ft.	Soil, gravel, shale.
12	517 ft.	36 ft. 11 in.	Shale and sandstone.
13	463 ft.	57 ft. 5 in.	Shale and sandstone.

Total... 2,885 ft. 4 in. 41 ft. 10 in.

In all, 69 days were worked, making the average nearly 42 ft. drilled per 10 lb. shift, as shown in the table.

The cost of the work is shown below. A two horse team was used to haul water and other supplies. The machine used 4 gals. of gasoline per day. It will be noticed that the cost of the team was nearly 50 per cent of the total cost.

Drill Runner, 69 days @ \$2.50.....	\$172.50
Helper, 69 days @ \$2.00.....	138.00
Team, 69 days @ \$4.00.....	276.00
276 gals. gasoline @ 12 cents.....	33.12

Total\$619.62

This gives a cost of 21½ cents per ft. of hole. To this should be added an allowance for plant and superintendence. It will be noticed that some of the holes are very shallow, thus necessitating frequent moves of the machine.

Cost of Drilling Copper Ore With Well Drillers.†—The following costs on drilling and blasting, and the methods of mining copper ore with a steam shovel at the Copper Flat Mines in Nevada, are abstracted from "Mines and Minerals."

*Engineering-Contracting, Nov. 18, 1908.

†Engineering-Contracting, Sept. 9, 1908.

The ore lies in a flat, and is estimated to be more than 200 ft. in depth, the ore occurring in a porphyry. It is capped with earth and rock to a depth of about 87 ft. This stripping and the ore are worked in trenches 50 ft. deep.

Cost of Drilling.—The holes are put down by two Keystone No. 6 traction drills, owned by the mining company and kept continually at work drilling to loosen ground for the steam shovels. The Keystone No. 6 machine is built specially for mineral prospecting and mine work, it being the largest machine made by the Keystone Driller Co., of Beaver Falls, Pa. The boiler is mounted on the same trucks with the engine, and the machine is propelled on traction wheels. The engine is 14-hp. The derrick is 34 ft. high. The machine weighs 16,000 lbs. and costs, without tools or equipment, \$1,375. This machine will drill holes from 1,000 to 1,200 ft. deep.

The drills use a 5½-in. bit which gives a hole about 6½ in. in diameter, and the holes are put down to a depth of about 60 ft. The holes are spaced on 35-ft. centers and are back from the breast of the bench 40 ft. This is the usual spacing; however, where hard masses of tough carbonate ores are encountered, holes are about 15 ft. apart and 15 ft. from the breast. Each machine requires a driller, who is paid \$4 per day, and an assistant, who is paid \$3 per day. Nine-hour shifts are worked. A 60-ft. hole is put down in two shifts, or 18 hrs., thus 3 ft. and 5 in. of hole is drilled per hour. For each hole the boiler burns 1½ cords of wood, costing \$6 per cord. The cost of drilling one 60 ft. hole is as follows:

Driller, 3 days.....	\$ 8.00
Assistant, 2 days.....	6.00
Fuel	10.00
Oil and waste.....	0.55
Extra parts, repairs, renewals.....	2.15
Rope wear per hole.....	3.50
Estimated interest and depreciation.....	2.00

Total\$32.20

This gives a cost per lineal foot of hole as follows:

	Per lin. ft.
Labor	\$0.23
Fuel	0.17
Oil and waste.....	0.01
Repairs and renewals.....	0.04
Rope wear.....	0.06
Interest and depreciation.....	0.03

Total\$0.53

Cost of Blasting.—In blasting any material the amount of explosives used naturally varies with the location and depth of holes and with the hardness of the materials. However, the average amount of explosives used in this work was obtained, and was as follows: The holes were sprung with two 50-lb. boxes of 40 per cent dynamite, costing \$15.40 for 100 lbs. Then the hole was reamed out, and from 20 to 30 kegs of black powder were used in the blast, the average being 25 kegs or 625 lbs., costing \$2.25 per keg. This gave a total cost for explosives of \$71.65.

Assuming that a block, $35 \times 40 \times 60$ ft., is broken by the hole, we have a total of 3,111 cu. yds. of material moved by the black powder per cu. yd. of material, or 0.23 lbs. of explosives per cu. yd. for both springing and blasting. This is a very small amount of powder to be used for rock blasting. The total cost per cu. yd. for drilling and blasting was:

	Per cu. yd.
Drilling	\$0.010
Blasting	0.023
Total	\$0.033

This cost of $3\frac{1}{2}$ cts. per cu. yd. is very low for the hard material. On the other hand, for the earth capping this cost is a little high; however, the cost given is an average for the two materials.

Steam Shovel Work.—Three 95-ton and one 70-ton Bucyrus steam shovels are used to load the blasted material. The dippers are equipped with manganese steel teeth, the repairs on them being very light. The shovels load the stripping into two wayside dump cars of $3\frac{1}{2}$ cu. yds. capacity. The trains are pulled by 45-ton locomotives. Ten cars make up a train.

The ore is loaded into 50-ton bottom-dump cars for direct transportation to the concentrator. The ore is hauled by the railroad company and not by the mining company. Exact records of the cost of the steam shovel work are not available, but the work done by them in the first six months shows that the cost is much less than other methods in vogue in that part of the west, the saving being enough to make profitable the mining of low grade ores with this method, when it is not possible to make a profit on higher grade ores with other methods.

Cost of Tunneling, Shaft Sinking and Mining, Cross-References.—Data on these subjects will be found in the following sections of this book: Railways, and Sewers. Consult the index under "Tunnels," "Shafts." Consult Gillette's "Rock Excavation."

Cost of Subaqueous Rock Excavation.—On jobs of size sufficient to warrant the installation of a good plant, the cost of drilling, blasting and dredging rock of the consistency of hard limestone averages about \$2.50 per cu. yd., although I have records of work where the actual cost (including plant repairs, interest, and depreciation), was less than \$2 per cu. yd. For discussion of methods and for cost records, see my book on "Rock Excavation."

Costs of Chamber Blasting.—By this method, one or more small tunnels are driven into the face of a rock hill that is to be quarried. Generally such a tunnel runs in not more than 50 ft., and then it branches right and left, forming a T. Heavy charges of black powder or of Judeon are placed in the branches of T, and fired. As much as 350,000 tons of rock have thus been shattered at one blast. Costs as low as $2\frac{1}{2}$ cts. per cu. yd. (solid) are on record for breaking rock in this way. See Gillette's "Rock Excavation."

A similar method has often been used on a smaller scale for blasting hardpan that was so full of boulders as to make drilling very expensive.

SECTION IV.

ROADS, PAVEMENTS, WALKS, ETC.

Definitions.—Asphalt Pavements.—In the broad sense of the term, an asphalt pavement is any pavement composed of mineral particles cemented together with asphalt. This definition includes ordinary asphalt pavement, Bitullithic, Petrolithic, etc., as well as "oiled roads" of the California type, also "asphalt macadam." All these, in reality, are species of asphalt pavement. Asphalt pavement, however, is a term generally used in a narrower sense, and applies usually to a class of pavement (sometimes called "sheet asphalt" to distinguish it from "asphalt block" pavement), the wearing coat of which is composed of sand, limestone dust and asphalt, mixed hot in a mechanical mixer, laid upon a "binder course" and rolled. The "binder course," or "binder" is usually a thin layer of finely broken stone mixed hot with asphalt, spread upon a concrete base and rolled. However, it is frequently the practice to use only a "naphtha binder," which is merely a coat of what might be called an asphalt paint applied with brushes to the surface of the concrete base. In either case, the object of the "binder" is to prevent the asphalt wearing surface from creeping along or peeling away from the concrete base.

"Lake asphalt" is an asphalt obtained from Trinidad Lake, or other similar deposit.

A "rock asphalt pavement" is one made of rock which is found in deposits that are impregnated with asphalt.

An "asphalt block pavement" is made of blocks or bricks, composed of graded sizes of broken stone, sandstone dust mixed with asphalt, and compacted in a block machine under great pressure. The standard size for blocks is 3 x 5 x 12 ins. (See Peckham's "Solid Bitumens," p. 310.)

Barrel.—The most common size of barrel in which asphaltic oil is shipped holds 42 gals. The standard size of tar barrel appears to be 52 gals.

Base.—The artificial foundation on which the "wearing coat" of a pavement rests. The most commonly used base is concrete, generally 6 ins. thick. The word base is preferable to the word foundation.

Belgian Block Pavement.—A stone block pavement, the stones being rectangular in shape and of a size about 3 x 6 x 10 ins., although varying more or less, except in the matter of thickness which is usually 6 ins. Granite and sandstone are about the only

kinds of stone used in America, although trap was formerly used to a considerable extent.

Berm. The "shoulder" or "wing" of earth between the edge of the paved part of a country road and the edge of the ditch.

Binder.—A term used in several senses: (1) The screenings, or soil, used to bind a macadam road together; (2) the "binder coat" between a concrete base on an asphalt wearing surface (see Asphalt Pavement); (3) any bituminous material used to bind mineral fragments together.

Bituminous Pavement.—A wearing coat composed of broken stone, sand, stone dust and a bituminous cement, usually asphalt, mixed in a machine, and laid upon a base of concrete or other material.

Bitumen.—No generally accepted definition of this term exists. Peckham's "Solid Bitumens," p. 80, contains the following: "Bitumen, a generic term including substances occurring in nature, in outflows or springs, and in veins, as natural inflammable gas, fluid petroleum, viscous maltha and solid asphaltum and asphaltite. It also occurs saturating and mixed with limestones, sandstones, sand or earthy matter. These mixtures are called asphalt." Asphalt, pitch, tar, etc., are commonly included in the generic term bitumen.

Blind.—A surfacing of screenings or gravel on a macadam road.

Blind Train.—A trench filled with broken stone.

Block Pavement.—A pavement made of stone, brick, wood, or asphalt blocks. Vitrified bricks of large size ($3\frac{1}{4} \times 8\frac{1}{2} \times 4$ ins.) are called "blocks," to distinguish them from bricks of a smaller size ($2\frac{1}{2} \times 8\frac{1}{2} \times 4$ ins.).

Bottoming.—The base of a Telford pavement, consisting of large stones set on edge forming a rough pavement. On this "bottoming" is laid the macadam wearing coat, the whole forming a Telford pavement or road.

Box Culvert.—A small culvert with an opening of rectangular shape. Originally such culverts had rubble masonry sidewalls for the sides, cobble pavement for the bottom and slabs of stone ("coverstones"), resting on the sidewalls, for the top. Box culverts are now made entirely of concrete, as a rule.

Box.—The unit of measure of mixed ingredients for an asphalt pavement is commonly the "box" of 9 cu. ft. The amount of compression of the mixture used to make an asphalt wearing coat is variously estimated at $\frac{1}{6}$ to $\frac{1}{4}$. Hence a 9-cu. ft. "box" of mixture will yield $7\frac{1}{2}$ to 6 cu. ft. of compacted wearing coat, which will make 5 to 4 sq. yds. of wearing coat 2 ins. thick—5 sq. yds. if the shrinkage is only $16\frac{2}{3}\%$; 4 sq. yds. if the shrinkage is $33\frac{1}{3}\%$ under the roller.

Brick.—Vitrified paving brick are made of selected clay or shale burned so as to produce an exceedingly hard and tough brick.

Broken Stone.—Stone that has passed through a rock crusher (or has been broken to small size with hammers), also called "crushed stone." When it has not been screened into different sizes, it is called "run of crusher," or "crusher run." The smallest size, generally $\frac{1}{2}$ or $\frac{3}{4}$ down to dust, is called "screenings." Sometimes a

macadam road is called a "broken stone road," but the term macadam is preferable. Broken stone is sometimes called "ballast," which is only objectionable because of possible confusion with the ballast of a railway track.

Catch-Water.—A broad, shallow paved ditch across a road built on a steep grade, for the purpose of diverting surface water to side ditches. In climates where snow accumulates, giving a sharp crown to a road does not serve sufficiently well to divert the melting snow to the side ditches. Hence the use of catch-waters on steep grades where melted snow would follow the wheel tracks down the center of the road and do damage to its surface if not diverted at short intervals.

Cement Curb.—A curb made of concrete faced on the front and top with cement mortar.

Cement Walk.—A footway, or walk, having a concrete base and a cement mortar wearing coat.

Coal Tar.—See Tar.

Cobblestone Pavement.—A pavement of rounded cobbles. Seldom used except for paving gutters.

Corduroy.—A crude road made of split or round logs (usually about 6 ins. diameter) laid side by side, not unlike railway ties spaced so close as to touch one another. For a cheap road over marshy ground, the corduroy road is often used in a timbered country.

Cover Stone.—See Box Culvert.

Creosoted Wood Block.—Dried timber blocks impregnated with oil of creosote (dead oil of tar), 16 to 20 lbs. of oil per cu. ft. of timber. Creosote weighs 8.8 lbs. per gal.

Crossing.—A footwalk across a street, usually made of stone

Crown.—The arch or camber of the surface of a road or street; the transverse profile of a roadway.

Crushed Stone.—See Broken Stone.

Crusher Run.—See Broken Stone.

Culvert.—A waterway under a roadway. See Box Culvert.

Curb.—A miniature retaining wall at the outside of a sidewalk and forming one side of the gutter; an edge stone.

Cushion.—A thin layer of sand or screenings under the wearing coat of blocks (stone, brick, etc.).

Cushion Coat.—A coat of $\frac{1}{2}$ -in. of asphaltic mixture upon which the wearing or surface coat of an asphalt pavement is laid. Now replaced by the "binder coat." See Asphalt Pavement.

Flagging, or Flag Stone.—A thin slab of stone for a crosswalk or sidewalk.

Foundation.—The base (usually of concrete) which supports the wearing coat of a pavement; also cinders, gravel, broken stone, or the like, under a cement walk. It is preferable to use the word base when speaking of the concrete foundation of a pavement.

Gage.—The "track" of wagon wheels, measured from center to center of the tires; usually 4 ft. 8 ins. to 5 ft.

Gallon.—The U. S. gallon contains 231 cu. ins. = 0.12288 cu. ft. A cu. ft. contains 7.48 gals. A gallon of water weighs 8.34 lbs.; or 1 lb. of water = 0.12 gal. See Barrel.

Grade.—The rate of per cent. of rise or fall of the longitudinal profile of a road. A 1% grade means a rise of 1 ft. vertical in 100 ft. horizontal. Grade is also a verb, meaning to excavate or fill to grade line.

Grader.—A "road machine" having a steel blade for leveling, scraping or "drifting" earth. The word "grader" is also applied to an "elevating grader," a machine having a plow that casts the earth upon an endless belt which elevates the earth into a wagon traveling alongside, or deposits it in an embankment alongside.

Granolithic Walk.—A cement walk whose surface coat contains finely broken stone.

Great Square.—An area of 10,000 sq. ft. (or 100 "squares"), sometimes used as the unit of street sweeping. It is preferable to retain the old unit of 1,000 sq. yds. for that purpose, since the sq. yd. is the unit of first cost of pavements.

Grout.—A flowing mortar, either of pure cement and water, or of cement, sand and water. Commonly used for filling the joints of brick pavement; also, in some places, for filling joints of Belgian block pavement.

Grab.—To remove roots and stumps.

Guard Rail.—A fence along an embankment, or a bridge, to prevent vehicles from running over its edge.

Halwood Block.—A paving brick made of "mica shale," clay and sand; size, 3 x 4 x 9 ins.

Head Rail.—Same as Guard Rail.

Heaven Pavement.—A concrete pavement made by grouting broken stone with Portland cement mortar and rolling with a steam roller.

Hot Stuff.—The hot mixture of sand, stone dust and asphalt, used for making an asphalt pavement.

Leveler.—A machine somewhat similar to a "road machine," but much smaller; used for leveling earth subgrades, also for leveling or spreading the broken stone for a macadam road.

Macadam.—A pavement made of graded sizes of broken stone held together by the mineral colloids of the stone. This "mineral glue or jelly," as the colloids may be called, is not visible, and its binding action was not recognized until the recent investigations of Cushman, Chemist of the Office of Public Roads, U. S. Dept. of Agriculture.

Asphalt macadam is a macadam in which the binder is asphalt. Ditto, tar macadam.

Mastic.—A mixture of bituminous limestone and refined asphalt, formerly much used for sidewalks.

Metal.—The broken stone used for macadam; often called "road metal." Perhaps a better term is ballast. At least it is no more ambiguous.

Mile.—5,280 ft., 1,760 lin. yds. A mile long and 10 ft. wide contains 5,366½ sq. yds. = 1.21212+ acres. A mile long and 16 ft. wide contains 9,386.7 sq. yds.

1 mile long x 10 ft. wide x 1 in. deep = 162.96 cu. yds.

1 mile long x 10 ft. wide x 6 ins. deep = 977.76 cu. yds.

1 mile long x 16 ft. wide x 1 in. deep = 260.727 cu. yds.

1 mile long x 16 ft. wide x 6 ins. deep = 1,564.36 cu. yds.

1 mile long x 16 ft. wide x 6 ins. deep = 1,564.42 cu. yds.

Oiled Road.—An earth road sprinkled with asphaltic oil so as to form a crust of mineral matter bound together with asphalt. This is the "surface oiled road" originally developed in California, but greatly improved in recent years by mechanical mixing of the asphaltic oil with the soil to a depth of several inches and compacting with a rolling tamper.

Pavement.—A floor-like covering built upon the soil to form a firm, unyielding roadway for wheeled vehicles and animals.

This definition includes any artificial highway covering built upon an earth subgrade, from the cheapest "gravel road" to the most expensive granite block pavement. English engineers have been in the habit of not calling macadam a pavement, but, as macadam performs every function that any pavement performs, there is no logical reason for excluding it from the list of pavements.

Every pavement has three functions to perform:

(1) Distributing concentrated wheel loads over the earth subgrade.

(2) Roofing the earth subgrade so as to prevent its saturation with water.

(3) Giving a hard, clean, smooth (but not slippery) surface that reduces rolling friction.

Pavements generally consist of two parts, (1) a "base" which performs the function of distributing the wheel load, and (2) a wearing coat which sheds rain and provides a durable, smooth surface. The wearing coats commonly used for road and street pavements may be divided into 6 types:

Type 1. Granular minerals bound with mineral glue (or mineral jelly).

Type 2. Granular mineral bound with bitumen.

Type 3. Granular mineral bound with Portland cement.

Type 4. Stone blocks.

Type 5. Wooden blocks.

Type 6. Brick.

By the term "granular mineral" we mean fragments of mineral matter of any size from dust up to fragments as large as hens' eggs, or even larger, whether the fragments have been produced artificially by crushing or pulverizing, or by the forces of nature.

By the term "mineral glue" we mean the "colloids" which Cushman has proved to be the cementing element of rock dust, which causes macadam to bind, and to which the "sticky" properties of clay are attributable.

Type 1 includes:

- (a) Sand-clay roads.
- (b) Gravel roads.
- (c) Shell roads.
- (d) Macadam.

Type 2 includes:

- (a) Oiled roads.
- (b) Tar macadam, or tar concrete.
- (c) Asphalt macadam, or asphalt concrete.
- (d) Asphalt pavement, (1) sheet and (2) block.
- (e) Bitulithic pavement.
- (f) Petrolithic pavement.

Type 3 includes:

- (a) Concreta.
- (b) Macadam grouted with cement (Hassam pavement).

Types 4, 5 and 6 are self explanatory.

Pavers.—Men who lay paving blocks; also the blocks themselves, particularly the small size paving bricks ($2\frac{1}{2} \times 8\frac{1}{2} \times 4$ ins.), as distinguished from the large size called "blocks" ($3\frac{1}{2} \times 8\frac{1}{2} \times 4$ ins.).

Paving Cement.—A mixture of asphalt tar and still wax.

Petrolithic Pavement.—A pavement made of mineral matter (soil, broken stone or the like) mixed with a bituminous binder (asphaltic oil or tar) and compacted into a uniformly dense mass with a rolling tamper (a roller provided with projecting tamper, feet or "spuds"). Where the traffic is light, natural soil is ploughed up, pulverized and mixed with asphaltic oil, using a road machine and a "cultivator" for mixing. Then it is tamped so as to form a pavement 4 to 8 ins. thick. Where the traffic is heavier, the pavement base is made of the natural soil as just described, but a wearing coat is provided, consisting of broken stone or gravel of graded sizes mixed with the bituminous binder and tamped so as to form a layer 2 to 4 ins. thick. This is often called Petrolithic macadam.

Pitch.—Any tar or asphalt, or mixtures of the same, may be called pitch. The term is not definite. See Peckham's "Solid Bitumens."

Profile.—The line of intersection of a vertical plane with the earth's surface; ordinarily applied to the longitudinal profile of the ground over which a road is to be built. The transverse profile is the cross-section.

Ravel.—When the stones of a macadam road are displaced by traffic, it is said to "ravel."

Right of Way.—The land owned by the public for highway purposes.

Road.—In America the term road is applied only to country highways. In England it is applied also to city streets.

Road Machine.—See Grader.

Road Oil.—A bituminous (generally asphaltic) oil for sprinkling on a road to lay the dust.

Run of Crusher.—See Broken Stone.

Roller.—The ordinary steam roller is a 10 to 15-ton locomotive

with broad-tired wheels. A corrugated roller is generally a horse-drawn roller having several rolling discs on the same axle, discs of large and small diameter alternating so as to produce a "corrugated" appearance. This type of roller is supposed to be more effective than a smooth roller for compacting earth embankments. A tamping roller, or rolling tamper, is a roller having projecting tampers (or feet, or "spuds") which penetrate the loosened earth and begin compacting it from the bottom up.

Sand Cushion.—A thin layer of sand underneath a brick or block pavement. See Cushion.

Scarify.—To pick up or loosen old macadam preparatory to resurfacing it.

Screenings.—The fine product of a rock crusher, usually from dust up to $\frac{1}{2}$ to $\frac{3}{4}$ in. in size. See Broken Stone.

Shaping.—The process of giving the final finishing to a subgrade, including the rolling of the subgrade.

Shoulder.—See Berm.

Slope Stake.—A stake set to mark the toe of a "fill" (embankment) or the top outer edge of a "cut" (excavation).

Spreader.—See Leveler. A "spreader wagon" is a dump wagon designed to discharge its load in a layer of uniform thickness.

Square.—100 sq. ft.; a unit of area occasionally used in measuring pavements, but one not to be recommended now that the sq. yd. (9 sq. ft.) is the common unit. See Great Square.

Subgrade.—The graded surface of the soil upon which a pavement rests.

Tar.—Coal tar is a by-product in the manufacture of coal gas or coke. See Barrel.

Tarvia.—A refined tar especially made for road use.

Telford.—A pavement consisting of a base, or "bottoming," of large stones set on edge, supporting a wearing coat of ordinary macadam. See Macadam.

Thank You, Ma'am.—A catch-water. See Catch-Water.

Ton.—Unless otherwise stated, the ton of 2,000 lbs. is used in this book. The "gross ton" of 2,240 lbs. is not ordinarily used in America as a unit for broken stone, asphalt, or, indeed, for any road or street material.

Tractive Resistance.—The frictional resistance that a load on wheels offers.

Wearing Coat.—The surface layer or coat of a pavement. See Pavement.

Wings.—See Berm.

Wood Block.—See Creosoted Block.

Vitrified Brick.—See Brick.

Yard.—When the word yard is used in reference to a pavement, the square yard (9 sq. ft.) is usually meant. The lineal yard is never used in America as a unit for road or street work.

Water Table.—A horizontal slab of concrete or stone forming the floor of a gutter next to a curb.

Cross-References to Excavation and Rock Crushing.—Since the principal items of cost of excavating earth and rock are often much the same, whether for a road or for a railway, I have given most of the data on excavation in the Earth Excavation and Embankment Section and in the Rock Excavation Section of this book.

The cost of crushing rock for macadam, concrete, or other purposes, is also given in the Rock Excavation Section. Some examples of the cost of grading roads will be found, however, in this Road and Street Section. See page 332.

Units Used in Measuring Macadam.—Due to the fact that macadam is measured in various ways by different engineers, there has been much confusion in recording costs. The following are some of the different units that engineers have used:

- (1) Cu. yd. of consolidated macadam, measured in finished road.
- (2) Cu. yd. of loose stone, including screenings, measured in wagons.
- (3) Cu. yd. of loose stone, measured, on the road, but not including screenings or binder.
- (4) Sq. yd. of consolidated macadam.
- (5) Sq. yd. of loose stone (sometimes excluding screenings).
- (6) Ton (usually 2,000 lbs., but sometimes 2,240 lbs.) of stone used to make the macadam, usually including the screenings or binder, but not always.

In view of the great uncertainty as to what may be meant by the expression "cubic yard of macadam" or "cubic yard of stone," every writer should be careful to tell exactly what he means.

Of the various units above mentioned, I prefer the first—the cubic yard of completed macadam.

However, the ton of 2,000 lbs. is often a convenient unit for measuring the material in a macadam road, and is also likely to be used extensively. When the ton is used as the unit, care should be taken to give the weight of the loose broken stone per cubic yard, so that conversions can be made.

Since loose broken stone consolidates about 10% when hauled a short distance in a wagon or car, care should be taken to state where the measurement of volume was made.

Macadam roads vary so greatly in thickness, that it is particularly desirable to use the cubic yard of consolidated macadam as the unit, instead of the square yard; but the thickness of the macadam, after compacting, should always be stated, for the per cent of screenings, or binder, varies with the thickness, and the amount of rolling is less per cubic yard for thick macadam than for thin macadam.

Items of Cost of Macadam.—The following are all the items usually involved in macadam construction done by a contractor:

Materials:

- Broken stone (coarse).
- Screenings, or binder.
- Freight on stone and screenings.
- Water for sprinkling.

Labor:

Loading stone and screenings into wagons.

Hauling stone and screenings.

Spreading stone (coarse).

Spreading screenings, or binder.

Rolling.

Sprinkling.

Foreman.

General Expense:

Superintendent, watchman, waterboy, timekeeper, and clerks,
insurance of workmen, etc.

Supplies and Plant:

Coal for roller.

Oil and waste for roller.

Interest, depreciation and repairs on roller.

Interest, depreciation and repairs on wagons.

Interest, depreciation and repairs on small tools.

In the foregoing summary, it is assumed that the broken stone and screenings are either purchased, or that, if quarried and crushed by the contractor himself, the cost of quarrying and crushing is kept entirely separate from the cost of building the macadam. The reader will find costs of quarrying and crushing in the section on Rock Excavation and Quarrying.

It is also assumed that the grading, including preparing the subgrade, is likewise kept separately, for to do otherwise leads to great confusion, as the yardage and cost of grading have no relation whatsoever to the yardage of macadam and its cost.

While the size of each particular job should be recorded, stating length, width and thickness of the compacted macadam, writers only confuse their records by giving *total costs* of each of the above items. What a reader desires is *unit costs*, that is the cost of each item in terms of the cubic yard of compacted macadam as the unit. Then, if the writer has stated the total number of cubic yards involved, it is a simple matter of multiplication to arrive at total costs, should anyone desire totals.

Quantity of Stone and Binder Required for Macadam.—About ten years ago I called attention to an error that had been copied in text books from a very early day down to the present, namely the statement that a layer of loose stone 6 ins. thick can be compacted under a roller till it is 4 ins. thick. No such compression is possible, but it often happens that the stone is driven 1 to 2 ins. into the subgrade. On a hard earth subgrade, it never requires more than 1.3 cu. yds. of coarse loose stone (exclusive of the screenings or binder) to make 1 cu. yd. of rolled or compacted stone, and where the stone is very tough the "compression" is even less.

The percentage of binder or screenings required to fill the voids in the rolled stone varies somewhat with the thickness of the macadam. To ascertain the thickness of the coat of screenings necessary to fill the voids in the rolled stone, divide the thickness of the rolled stone by 4 and add $\frac{1}{4}$ inch. Thus, for a 6-in. macadam road,

there will be required $(6 \div 4) + \frac{1}{2} = 1\frac{5}{6}$ ins. of screenings. This is equivalent to 0.3 cu. yd. of screenings per cu. yd. of macadam. Therefore, to make a cubic yard of finished 6-in. macadam requires 1.3 cu. yds. of coarse stone and 0.3 cu. yd. of screenings, or 1.6 cu. yds. measured in the wagons to make 1 cu. yd. of compacted macadam. Stated differently:

7.8 ins. of loose stone ($\frac{1}{2}$ to $1\frac{1}{2}$ -in.) will roll to 6 ins.

1.8 ins. of screenings (less than $\frac{1}{2}$ -in.) will fill voids.

9.6 ins. of loose stone and screenings will make 6 ins. of macadam.

If the stone weighs 2,400 lbs. per cu. yd., we need 1.56 short tons of coarse stone and 0.36 short ton of screenings, a total of 1.92 tons required to make 1 cu. yd. of finished macadam. If the stone is a heavy trap rock, weighing 2,700 lbs. per cu. yd., we need 1.75 short tons of coarse stone and 0.41 short ton of screenings, a total of 2.16 tons per cu. yd. of finished macadam. This estimate, based upon my own records, checks very well with records published by the Massachusetts Highway Commission.

On 2.6 miles of 6-in. New York State macadam, 1,600 cu. yds. of screenings were required to bind 4,000 cu. yds. of macadam rolled in place. This is equivalent to 0.4 cu. yd. of screenings per cu. yd. of macadam, or a depth of 3.4 ins. of loose screenings to bind the 6 ins. of rolled macadam. This large amount was due to the specification requirement that a "wearing coat" of screenings be left on the road.

The contractor is cautioned against careless examination of road specifications, for many engineers require the contractor to grade the subgrade exactly to grade and then put on enough stone to bring the finished macadam up to the established road grade. This causes the contractor to lose all stone that is driven into the subgrade by the roller, which in sand, or in soft wet clay, may amount to 2 ins. or more of loose stone.

Some specifications also foolishly require a $\frac{1}{2}$ -in. "wearing coat" of screenings to be left on the finished road, and this also amounts to a good many cubic yards of wasted material in a mile.

The roadmaker will do well to carry in mind the following data:
 A bed 1 in. thick, 10 ft. wide and a mile long, contains 163 cu. yds.
 A bed 6 ins. thick, 16 ft. wide and a mile long, contains 1,564 cu. yds.

Few rocks are soft enough to yield a sufficiently large percentage of screenings to bind the macadam; in which case screenings must be imported, unless the specifications permit the use of loam, sand, or clay.

Macadam roads are usually made 4 to 6 ins. thick after rolling, and 12 to 16 ft. wide. I have often urged the more common use of single track macadam roads, 8 ft. wide, with turnouts (16 ft. wide) located every few hundred feet apart.

Cost of Loading Stone From Cars Into Wagons.—A good workman, shoveling stone from a flat car into a wagon, will load 20 cu. yds. (loose measure) per 10-hr. day, giving a cost of $7\frac{1}{2}$ cts. per cu. yd. when wages are \$1.50.

Where the amount to be handled warrants the use of a derrick, and clamshell bucket, a much lower cost can be attained. Consult the section on Rock Excavation for details of cost of loading broken stone. (See page 197, etc.)

Cost of Loading Stone From Bins into Wagons.—If the broken stone is to be hauled direct from the crusher, bins should always be erected to receive the broken stone. The bottom of the bin should have a slope of not less than 1 to 1, and should be lined with sheet iron. If the slope is flat, say $1\frac{1}{2}$ to 1, a wagon cannot be loaded in much less than 7 mins., and then a potato-hook or hoe must be used to keep the stone moving. But, with a 1 to 1 slope, the stone runs freely, and a wagon can be loaded with $1\frac{1}{2}$ cu. yds. in 2 mins. or less.

Usually one man operates the bin gates and assists the driver in trimming the load on the wagon. Hence the unit cost of loading from bins is the wages of the bin man divided by the total number of cubic yards crushed daily. If his wages are \$1.50 and the crusher output is 65 cu. yds., the cost of loading from the bins is 2.3 cts. per cu. yd.

Cost of Hauling Stone in Wagons.—When wagons are loaded from cars, it is not economic to have more than 4 men shoveling into a wagon. These men will load a cubic yard of broken stone in about 6 or 7 mins., if working briskly. If a team (with driver) receives \$3.50 per 10-hr. day, each minute of team time costs 0.6 ct.; hence the lost team time while loading amounts to about 4 cts. per cu. yd. If the loading is done from bins, the lost team time is about $1\frac{1}{2}$ min. per cu. yd., or less than 1 ct. per cu. yd.

The lost team time at the dump is 5 mins. for a load of $1\frac{1}{2}$ cu. yds., or more than 3 mins. per cu. yd., if flat-bottom dump wagons are used, costing nearly 2 cts. per cu. yd. for team time lost dumping. In dumping from a flat-bottom wagon, dump the load in 3 small piles, to reduce the labor of spreading.

Up-to-date contractors are now using bottom dump wagons extensively on roadwork. In dumping stone from such a wagon, fasten a chain around the body of the wagon so that the bottom doors can open only 6 ins. when the load is dumped, and keep the team traveling while dumping, so as to spread the load as much as possible. When such wagons are used, there is practically no lost team time dumping.

Special "spreader wagons" are frequently used, and, in that case also, there is practically no lost team time dumping the load.

It will be seen that the lost team constitutes a fixed cost per cu. yd., which may range from 1 ct. per cu. yd., where loading is done from bins and unloading from bottom dump wagons, to 7 cts. per cu. yd., where wagons are loaded from cars and where flat bottom wagons are used. For subsequent illustration, we shall assume 4 cts. per cu. yd. for lost team time, wages of team being \$3.50 per 10-hr. day.

As $1\frac{1}{2}$ cu. yds., or 1.9 tons, is a common load of broken stone hauled over earth roads, and as a common speed is $2\frac{1}{2}$ miles per hr.,

or 220 ft. per min., the cost of hauling is 28 cts. per load per mile, or 19 cts. per cu. yd. per mile, measured one way from the point of loading to the point of dumping (wagon returning empty), team wages being \$2.50 per 10-hr. day. To this must be added the fixed cost of lost team time, above given at 1 to 7 cts. per cu. yd.

If the earth roads are level and in good condition, a load of 2 cu. yds. may be hauled.

If the haul is over a good macadam road, 3 cu. yds., or 3.7 tons may be hauled, but it often happens that specifications foolishly prohibit any hauling over macadam before the rolling has been completed, in which case the contractor must usually begin construction at a point far from his stone supply and build the road back toward the stone supply, thus hauling over earth the entire distance, and doubling the cost of hauling.

In estimating the average length of haul on roadwork, bear in mind that the haul is never constant, and that at times the work will be too great for 5 teams, for example, but not enough to keep 6 teams fully busy. After estimating the cost by the above rules, for the actual average haul, I consider it fair to add about 15% to cover the added cost due to variable haul, and the added cost of team time due to delays at the crusher.

For discussion of the general subject of hauling, including traction engine hauling, see the last section of this book.

Cost of Spreading Stone By Hand.—When the stone is dumped in comparatively small piles on the subgrade, one man will spread 25 cu. yds. of the coarse broken stone in 10 hrs., at a cost of 8 cts. per cu. yd. when wages are \$1.50. This is my own record (12 years ago) for several thousand yards of stone delivered in flat-bottom wagons. Subsequently I developed the method of machine spreading, described hereafter, which greatly reduced the cost.

The following records confirm my own, all being recorded in recent issues (1907 to 1909) of *Engineering-Contracting*.

Mr. Curtis Hill states that each man averaged 28 cu. yds. per day, in Missouri.

Mr. A. N. Johnson states that spreading 44,000 cu. yds. cost 8 cts. per cu. yd. He gives the wages on about half the jobs, indicating an average of about \$2.00 a day for the whole work, which would mean that 25 cu. yds. were spread per man per day.

Mr. W. W. Crosby gives records for negro labor in Maryland, showing an average of 23 cu. yds. per man per day; wages were \$1.00 for 10 hrs.

The foregoing show what may be accomplished with energetic workmen, but there are numerous instances where the cost of spreading has been three times as high. For example, Mr. John McNeal states that the average cost was 2½ cts. per sq. yd. for spreading stone by city day labor on 14,000 sq. yds., in Easton, Pa., the macadam being 6 ins. thick after rolling. This is equivalent to 15 cts. per cu. yd. of consolidated macadam, or 34 cts. per cu. yd. of loose stone; and, as wages were \$2.00 per 10-hr. day, each man spread only a little more than 8 cu. yds. of loose stone per day.

However, a high cost of spreading is not of itself evidence of inefficiency. It frequently happens that engineers foolishly require all stone to be dumped upon platforms alongside the road, whence it is shoveled onto the road. In such cases, a man will not shovel and spread more than about 12 cu. yds. per day.

According to the common method of building a macadam road, the coarse stone is dumped in piles upon the subgrade, and spread with shovels and rakes. The screenings, however, are dumped in piles on the earth shoulders, and not on the subgrade. Then they are shoveled onto the coarser stone after it has been spread and well packed by rolling. This shoveling and spreading of the screenings costs much more per cubic yard of screenings than it costs to spread the coarse stone. A man will spread about 10 cu. yds. of screenings per 10-hr. day, making the cost 15 cts. per cu. yd. when wages are \$1.50. Screenings cannot be spread with a leveler.

Cost of Spreading Stone With a Leveler or Grader.—Twelve years ago I lit upon the idea of using a grader for spreading broken stone. The "grader," or "leveler," as it has been recently called, was of the type shown in Fig. 1, excepting that the rooters or teeth

Fig. 1. Leveler for Spreading Stone.

Fig. 2. Leveler for Spreading Stone.

were removed, as they are useful only in loosening hard earth on a subgrade that is being leveled. Fig. 2 shows another "leveler."

A "leveler" is a light machine having a steel blade about 5 ft. long, mounted in a frame, and capable of being raised or lowered. One team pulls the machine, and a man operates it, thus making the cost of operation \$5.00 per 10-hr. day when team and driver are \$3.50 and

operator \$1.50. At these wages it costs only 1 ct. per cu. yd. to spread the coarse broken stone, for 50 cu. yds. can readily be spread per hour from small piles dumped on the subgrade. However, the spreading thus done by the "leveler" is not as true to surface as is necessary before rolling, so the layer of stone must be gone over by a man using a potato-hook for a rake. This final hand leveling adds another 1 ct. per cu. yd., making the total cost 2 cts. per cu. yd. for spreading the coarse stone. The screenings cannot be spread satisfactorily with the machine, but they constitute only a small percentage of the macadam.

I have known contractors who have attempted to improve on this method by using a large "road machine," but never with as satisfactory results. The four to six horses on a road machine add unnecessarily to the cost for this light work of spreading stone. Moreover, a road machine is not turned around so easily and quickly, and the turning around is apt to tear up the subgrade.

Due to the speed at which a leveler works, it is unnecessary to have a team constantly hitched to it. I prefer to unhitch a team from the sprinkler wagon at intervals during the day, for a few minutes at a time, and hitch it to the leveler.

For the best results at the lowest cost, dump the broken stone on the subgrade in as small piles as possible. Never dump the stone on the earth shoulders at the side of the road.

There are now several firms who make these "levelers," among them being: C. N. Carpenter Supply Co., Canton, Ohio; The Baker Mfg. Co., 725 Fisher Bldg., Chicago; The Ohio Road Mach. Co., Oberlin, Ohio.

Cost of Rolling.—Based upon my own records of cost of maintaining and operating steam rollers (10-ton), which now extend over a period of 13 years, the following is the cost per day actually worked:

	Per day.
Engineman	\$3.50
6.25 ton (700 lbs.) coal at \$4 delivered	1.40
Oil, etc.	0.25
300 gals. (3¼ tons) water pumped and hauled 1 mile	1.00
Interest, 6% of \$2,500 ÷ 100 days	1.50
Current repairs, and renewals, 5% of \$2,500 ÷ 100 days	1.25
Depreciation (life 25 yrs.; sinking fund, 3% compound), 2.75% of \$2,500 ÷ 100 days	0.70
Total	\$9.60

It will be noted that I have assumed only 100 days per annum actually worked by a roller. In the northern half of America the road building season is not long enough to permit working much more than this; but it will sometimes happen that work is started early enough to enable at least 120 days to be worked, after deducting time lost on account of rains, etc.

Further data on depreciation and repairs of rollers will be found in subsequent pages.

Having established an approximate cost of \$10 per day worked,

For operating and maintaining a roller, the next step is to determine the fair average yardage of macadam compacted per day. A roller can be counted upon to compact all the stone crushed by a 9x16-in. jaw crusher, where the crusher is working on hard quarry stone and averaging about 65 cu. yds. of loose broken stone and screenings per 10 hr. day. These 65 cu. yds. of loose stone will make 40 cu. yds. of compacted macadam, or 240 sq. yds. of macadam 6 in. thick. Hence the cost of rolling is about 15 cts. per cu. yd. of loose stone (including screenings), or 25 cts. per cu. yd. of compacted macadam, or $4\frac{1}{4}$ cts. per sq. yd. of compacted macadam 6 in. thick. This cost includes the ordinary steam rolling given to the subgrade before spreading the broken stone.

If the subgrade is very compact, or if new macadam is being laid on old macadam, a roller is capable of consolidating 50% more than the above given amount. On the ordinary soil, even after rolling it with a corrugated roller or a steam roller, the broken stone does not come to rest quickly under rolling, but waves under the roller for a long time. If the subgrade has been tamped with a rolling tamper, however, the average soil is so compacted that the broken stone is not driven into it, and the amount of steam rolling of the macadam is very greatly reduced.

One of my records shows that in 72 working days of 8 hrs. each, a 10-ton roller compacted 4,000 cu. yds. (24,000 sq. yds.) of 6-in. macadam, the subgrade being a compact gravelly soil. This is equivalent to 55 cu. yds. of compact macadam, or 330 sq. yds. per 8 hr. day, or nearly 7 cu. yds. or 42 sq. yds. per hr. This is a rapid rate, but is still far below the rate that I secured in resurfacing an old macadam that had been thoroughly broken up with picks, namely, 300 sq. yds. per hr., details of which are given on page 253.

In rolling 6-in. macadam at Hudson, N. Y., Mr. H. K. Bishop found that 60 cu. yds. of compacted macadam, or 360 sq. yds., was the average 8-hr. day's work of a 10-ton roller, which is equivalent to 45 sq. yds. per hr.

Mr. F. G. Cudworth states that in resurfacing an old macadam, 2.9 ins. of loose trap rock and 2.1 ins. of screenings were spread and rolled, the 10-ton roller averaging 472 sq. yds. per 10 hr. day.

Mr. W. C. Foster states that, in resurfacing an old macadam, a 12-ton roller averaged 314 sq. yds. of 6-in. macadam per 10 hr. day.

The three following records are taken from recent issues of *Engineering-Contracting*.

Mr. Curtis Hill states that in building a new 7-in. macadam road in Missouri, 65 cu. yds. of loose stone (the full output of the crusher) were rolled per day.

Mr. John McNeal states that in building new 6-in. macadam streets at Easton, Pa., a 12-ton roller averaged 200 sq. yds. per day, although on one street the average was 270 sq. yds. per day. The work was done by day labor, which accounts for the low average.

Mr. W. W. Crosby states that in building a new 6-in. macadam

road in Maryland, 300 sq. yds. were rolled per day of 10 hrs., less than 0.2 ton of coal being used by the roller.

If macadam is to be of thickness greater than 6 ins. (measured after rolling), it is usually built in two layers. It is evident that the top layer will require less rolling than the lower layer.

Cost of Sprinkling.—The amount of water used per cubic yard of macadam is exceedingly variable, depending largely upon the nearness of the water supply and the whim of the inspector. If the haul for the water is short, it is usually economy to use an abundance of water, for water washes the screenings into the voids of the coarse stone ("puddles"), and reduces the amount of rolling necessary to jar the screenings into the voids. I have used as low as 30 gals. per cu. yd. of compacted 6-in. macadam, which is equivalent to 5 gals. per sq. yd.; and I have used as high as 120 gals. per cu. yd., or 20 gals. per sq. yd. of 6-in. macadam. It is usually safe to estimate on not more than 10 gals. per sq. yd. of 6-in. macadam, or 60 gals. per cu. yd. of compacted macadam.

The following records are taken from recent issues of *Engineering-Contracting*.

Mr. A. L. Valentine states that in building a 6-in. macadam road near Seattle, 9.3 gals. were used per sq. yd. Mr. W. W. Crosby states that 20 gals. per sq. yd. were used on a 6-in. macadam road in Maryland.

Mr. John McNeal states that, in one case, 16.8 gals. were used per sq. yd. of 6-in. macadam, and that, in another case, 16 gals. were used per sq. yd. of 10-in. macadam street.

In road building it is usually necessary to pump the water by hand, or with a small gasoline pump, from a creek, river or well. In 10 hrs. one man, with a hand pump, will raise 7,500 gals. of water to a height of 16 ft. into a tank from which it can be drawn off into the sprinkling wagon. Hence by working 8 hrs. a day, a man can furnish 3,400 gals. of water for 240 sq. yds. of 6-in. macadam. If wages are 15 cts. per hr., the cost of pumping to a height of 16 ft. is 1-50 ct. per gallon, or 1-5 ct. (one-fifth cent) per sq. yd. of 6-in. pavement where 10 gals. are used per sq. yd., or a trifle more than 1 ct. per cu. yd. of macadam.

On ordinary roads, unless there is a very steep pull from the creek or river bed, a sprinkling wagon holding 450 gals. (or 1.9 tons) of water can readily be hauled by a team. The team time required to load the sprinkler from a tank and discharge its contents on the road is ordinarily about 20 mins., costing 12 cts. for the 450 gals. when team is \$3.50 per 10-hr. day. With a traveling speed of 2½ miles per hr., the cost of hauling is 28 cts. per tank (450 gals.) per mile of haul from water supply to point of delivery.

Hence, to a fixed cost of 12 cts. per tank (for team item loading and discharging the water), add 28 cts. per tank per mile of haul.

With a haul of 1 mile the cost is, therefore, 40 cts. per tank of 450 gals., or less than 1-10 ct. (one-tenth cent) per gallon. If 10 gals. are used per sq. yd. of 6-in. macadam, the cost of hauling

water the first mile is, therefore, 1 ct. per sq. yd., or 6 cts. per cu. yd. of compacted macadam; and each subsequent mile costs 4 cts. per cu. yd. of macadam.

It generally happens, however, that when the haul is a mile, or less, a sprinkling wagon is kept going continuously, regardless of the amount of water used. In that case, if wages of team and driver are \$3.50 per 10-hr. day, and interest, depreciation and repairs of the sprinkling wagon are \$0.50 per day, the daily cost of \$4.00 must be divided by the amount of macadam compacted by the roller, or 40 cu. yds., making a cost of 10 cts. per cu. yd., or 1.7 cts. per sq. yd. of 6-in. macadam, regardless of how short the haul

In California, where the hauls for water are apt to be long, it is not unusual to see tank wagons holding 900 gals. or more, hauled by six horses. See page 322.

Summary of Cost of Macadam.—Based upon the foregoing rates of wages, etc., the following summary, Table I, is given:

TABLE I.—COST OF MACADAM.

Item.	Per cu. yd.	Per sq. yd. (6-in.).	Per ton (2,000 lbs.)
1 1.3 cu. yds. (1.62 tons) coarse stone f. o. b. cars at \$0.75.....	\$0.975	\$0.162	\$0.488
2 0.3 cu. yds. (0.38 tons) screenings, f. o. b. cars at \$0.75.....	0.225	0.037	0.112
3 2 tons (1.6 cu. yds.) freight at \$0.50....	1.000	0.167	0.500
4 1.6 cu. yds. loaded into wagons at \$0.08..	0.108	0.018	0.054
5 1.6 cu. yds. lost team time loading at \$0.04	0.064	0.011	0.032
6 1.6 cu. yds. hauled (1 mile) at \$0.20....	0.320	0.053	0.160
7 1.3 cu. yds. spread by hand at \$0.06....	0.078	0.013	0.039
8 0.3 cu. yds. spread by hand at \$0.16....	0.045	0.008	0.022
9 Rolling, \$10 ÷ 40 cu. yds. macadam....	0.250	0.042	0.125
10 Sprinkling, \$4 ÷ 40 cu. yds. macadam....	0.100	0.017	0.050
11 Foreman, 1/2 of \$4.00 ÷ 40 cu. yds. macadam.....	0.050	0.008	0.025
12 Night watchman (\$1.50), water boy (\$0.75), and 1/2 of timekeeper (1/2 of \$2.50); \$3.50 ÷ 40 cu. yds.....	0.088	0.015	0.044
13 General supervision, office expense, insurance, etc., at 8% of Items 4 to 12 inclusive	0.112	0.017	0.056
Grand total	\$3.415	\$0.569	\$1.707

The cost per cu. yd. relates to a cubic yard of macadam packed in place, and not per cu. yd. of loose stone.

The cost per sq. yd. is for macadam 6 ins. thick after rolling, and is, therefore, exactly one-sixth of the cost per cu. yd.

The cost per ton is for a ton of 2,000 lbs. of stone having a specific gravity of 2.7, weighing 4,546 lbs. per cu. yd. solid (or 2,500 lbs. per cu. yd. loose broken stone having 45% voids) and assuming that the completed macadam weighs 4,000 lbs. (2 tons) per cu. yd. of completed macadam, which is equivalent to a macadam having only

a little more than 10% voids after rolling and binding. Codrington states, in the *Encyclopedia Britannica*, that a piece of old macadam contained only 5% voids, as determined by careful weighing.

In considering each item, refer to the previous discussion.

If the stone is quarried near the road, item 3 (freight) will not exist, and item 4 (loading wagons) will be reduced to 1 ct. per cu. yd. of macadam; also item 5 (lost team time) will be reduced.

If the haul is 2 miles, item 6 will be exactly doubled; on the other hand, if the hauling can be done over a macadam road, this cost per mile can be cut in two, and it can be still further reduced if a traction engine is used.

If the coarse stone is spread with a "leveler," as it always should be, item 7 (spreading) will be exactly one-third as much as given; but item 8 will not be affected.

If the subgrade is naturally hard, or has been compacted with a rolling tamper having projected teeth or tamper, item 9 (rolling) may be reduced 30% or more.

If the haul of water for sprinkling is less than a mile, or if the sprinkler is not kept constantly busy, item 10 can be materially reduced.

Item 11 (foreman) is given on the basis of half the foreman's time being charged to the macadam, the other half being charged to grading; and the same being true of the timekeeper's time in item 12.

Item 13 (general supervision, etc.) is rated at 8% of all costs, except the cost of broken stone delivered on cars, for it is here assumed that the stone is purchased.

If wages of laborers and teams are greater than \$1.50 and \$3.50 per 10-hr. day, the above costs should be increased in direct ratio the increased wage.

Estimating the Cost of Macadam, New York State.*—For estimating a fair bidding price on the macadam used in New York State road construction, Mr. Henry A. Van Alstyne, has prepared the following data:

The actual cost of the crushed stone in bins is estimated at 85 cts. per cu. yd., measured loose. The cost of hauling this stone from the bins to the road is estimated at 85 cts. per cu. yd. (loose measure) per mile of haul. The cost of spreading, rolling and sprinkling the broken stone is estimated at 30 cts. per cu. yd. of loose measure.

It is estimated that it takes $1\frac{1}{4}$ cu. yd. of stone to make 1 cu. yd. of stone compacted under the roller; and that it takes $\frac{1}{2}$ cu. yd. of screenings to bind this stone. Hence in estimating the cost of a cubic yard of loose broken stone we have:

	Per cu. yd.
Crushed stone in bins	\$0.85
Hauling, $1\frac{1}{4}$ miles at \$0.35.....	0.60
Spreading, rolling, etc.....	0.30
Total (loose measure)	\$1.75

**Engineering-Contracting*, Aug. 1, 1906.

Based upon this method we have the following table of the cost of broken stone or screenings placed in the road:

Haul, miles.	Cost per cu. yd. (loose).
1%	\$1.75
2	1.85
2 1/4	1.95
2 1/2	2.05
2 3/4	2.20
3	2.30
3 1/4	2.40
3 1/2	2.50
3 3/4	2.60
4	2.70
4 1/4	2.80
4 1/2	2.90
4 3/4	3.00
5	3.10

Then the cost of a cubic yard of solid macadam is estimated as follows, assuming a haul of 1 1/4 miles:

	Per cu. yd. macadam.
1.33 cu. yds. broken stone at \$1.75.....	\$2.33
0.5 cu. yds. screenings at \$1.75.....	0.83
Total	\$3.21
Add 20% for profit	0.64
Contract price	\$3.85

This is practically \$3.90, and it is so entered in the following table:

Contract Price for Macadam with Screenings Binder.

Haul, miles.	Price per cu. yd.	Price per sq. yd. per inch of thickness. Cts.
1%	\$3.90	10.8
2	4.10	11.4
2 1/4	4.30	12.0
2 1/2	4.50	12.5
2 3/4	4.70	13.1
3	4.90	13.6
3 1/4	5.10	14.1
3 1/2	5.25	14.6
3 3/4	5.45	15.1
4	5.65	15.7
4 1/4	5.85	16.2
4 1/2	6.05	16.8
4 3/4	6.25	17.3
5	6.45	17.9

The above is based upon the use of stone screenings for the binder, as required for the middle and top course of macadam, which are usually 3 ins. thick (2 ins. middle course and 1 in. top course). But for the bottom course, which is usually 3 ins. thick, the specifications permit the use of sand as a binder instead of screenings. This sand is estimated at \$1 per cu. yd., loose measure, including loading, hauling, spreading, profit, etc., or 83 cts. per cu. yd. without

the 20% profit. Hence, for a haul of $1\frac{1}{4}$ miles, we have the following for the bottom course:

	Per cu. yd. macadam.
1.32 cu. yds. broken stone at \$1.75.....	\$2.33
0.5 cu. yds. sand filler at \$0.83.....	0.42
Total	\$2.75
Add 20% profit	0.55
Contract price	\$3.30

Based upon this method of calculation we have the following as the cost of the bottom course for different lengths of haul:

Contract Price for Macadam With Sand Binder.

Haul, Miles.	Price per cu. yd.	Price per sq. yd. per inch of thickness. Cts.
1 $\frac{1}{4}$	\$3.35	9.3
2	3.50	9.7
2 $\frac{1}{4}$	3.65	10.1
3 $\frac{1}{4}$	3.80	10.5
2 $\frac{3}{4}$	3.95	10.9
3	4.10	11.4
3 $\frac{1}{4}$	4.20	11.6
3 $\frac{3}{4}$	4.35	12.0
4	4.50	12.5
4 $\frac{1}{4}$	4.65	12.9
4 $\frac{3}{4}$	4.80	13.3
5	4.95	13.8
5 $\frac{1}{4}$	5.05	14.0
6	5.20	14.4

The foregoing data are based upon the assumption that loose broken stone costs 85 cts. per cu. yd. in the crusher bin. If the stone is delivered on cars the cost often is higher, and to this cost must also be added 15 cts. per cu. yd. of loose stone for shoveling the stone from the cars into wagons.

The rates of wages paid by contractors in New York State road-work are usually \$1.50 per 8-hour day for common laborers, and \$4 to \$4.50 per day for team and driver.

Prices Allowed for Extra Work on New York State Roads.*—A good many of our readers will be interested in two features of the latest specifications for macadam and gravel roads built by the State of New York. One feature is the method adopted to prevent unbalancing of bids, and the other feature is the specifying of unit prices which the contractor must accept for extra work.

The State Engineer's estimate of the quantities of every kind of work specified is given in detail, but the contractor is required to bid a lump sum for the road complete. This, of course, prevents unbalancing of bids. Then, to avoid disputes or law suits in case any or all of the quantities are increased or diminished the following clause is inserted in the contract:

"And in consideration of the acceptance of the foregoing proposal we hereby agree to accept the following named unit prices

**Engineering-Contracting*, Aug. 1, 1906.

(Table II) for any increase or deduction which may be made by the State Engineer for changes made under the provisions of the specifications for said improvement."

It should be added that for ordinary conditions the State Engineer estimates a minimum price of macadam with a sand binder (bottom course) at \$3.25 per cu. yd.; and for the other courses (middle and top), \$3.00 per cu. yd. including binder.

Very complete specifications for this road work have been prepared by Henry A. Van Alstyne, State Engineer, Albany, N. Y. Engineers engaged in road construction will find much valuable information embodied in these specifications.

Macadam Road Prices in Massachusetts.^a—Some interesting data in the construction of macadam roads in Massachusetts are given in a recent bulletin prepared by Austin B. Fletcher, secretary Massachusetts Highway Commission, and issued by the U. S. Office of Public Roads. According to this the average costs (by contract) to the state of Massachusetts of broken stone in place on state highways constructed in 1906 were as follows. For a road made of imported stone (trap rock), 6 in. deep at center and 4 in. deep at sides, the cost per ton in place was \$1.956; the cost per square yard in place was \$0.4245 and the cost per mile was \$5,498. One ton of stone made 2.13 sq. yds. of macadam. For a road made of imported stone (trap rock) 4 ins. deep throughout, the cost per ton in place was \$2.025; the cost per square yard in place was \$0.5393 and the cost per mile was \$4,746. One ton of stone made 2.76 sq. yds. of macadam. For a road made of local stone 6 ins. deep at center and 4 ins. deep at sides, the cost per ton in place was \$1.394; the cost per square yard in place was \$0.4201 and the cost per mile was \$3,696. One ton of stone made 3.32 sq. yds. of macadam. For a road made of local stone 4 ins. deep throughout, the cost per ton in place was \$1.533; the cost per square yard in place was \$0.3931 and the cost per mile was \$3,459. One ton of broken stone made 4.03 sq. yds. of macadam. The above costs per mile are equated on the basis of a road 16 ft. wide. The average contract prices for the several construction items exclusive of macadam were as follows:

Excavation per cu. yd.	\$0.438
Borrow per cu. yd.	0.562
Ledge excavation per cu. yd.	1.78
Cement concrete masonry, cu. yd.	3.86
Shaping road for broken stone per sq. yd.	0.029
Vitrified 18-in. clay pipe, in place, per lin. ft.	1.57
Vitrified 12-in. clay pipe, in place, per lin. ft.	0.766
Vitrified 10-in. clay pipe, in place, per lin. ft.	0.643
Vitrified 8-in. clay pipe, in place, per lin. ft.	0.570
Iron water pipe, 12 in., in place, per lin. ft.	2.20
Iron water pipe, 18 in., in place, per lin. ft.	3.75
Stone filling for V drains, in place, per cu. yd.	0.027
Guard rail, in place, per lin. ft.	0.277
Catch basins, in place (including catch basin frames and grates), each	35.74
Setting stone bounds	1.85

The price for cement concrete masonry does not include the co-

^aEngineering-Contracting, Oct. 16, 1907.

TABLE 11.—PRICES FOR ROAD WORK.

The following are unit prices for the items named, in place, complete:

Excavation of earth, or embankment rolled in place, per cu. yd.	\$ 40
Excavation of rock, per cu. yd.	1.25
Second-class Portland cement concrete, in place complete (1:2½:5), per cu. yd.	4.00
Third-class Portland cement concrete, or third-class masonry, in Portland cement mortar, in place complete (1:3:6), per cu. yd.	4.00
Third-class masonry laid dry, in place complete (rubble), per cu. yd.	3.50
Pointing old masonry, per sq. yd.	0.20
Rip-rap, in place complete, per cu. yd.	1.50
Telford base, in place complete (8-in. to 3-in. thick), per sq. yd.	0.75
Stone paving, in place complete (8-in. thick), per sq. yd.	0.75
Cobble gutters, in place complete, per sq. yd.	0.60
8-in. stone flagging, in place complete (for covering box culverts), per sq. ft.	0.80
Expanded metal, 8-in. mesh (or 3-16-in.) gauge, in place complete, per sq. ft.	0.10
Guard rail, in place complete (posts 7-ft. long, 8 c to c), per lin. ft.	0.20
Rustic guard rail, in place complete, per lin. ft.	0.15
Bridge rail, in place complete, per lin. ft.	0.60
1½-in. pipe rail, in place complete (for masonry bridges), per lin. ft.	1.00
12-in. cast iron pipe, laid in place complete, per lin. ft.	1.50
18-in. cast iron pipe, laid in place complete, per lin. ft.	3.50
8-in. vitrified pipe, laid in place complete, per lin. ft.	0.30
12-in. vitrified pipe, laid in place complete, per lin. ft.	0.60
18-in. vitrified pipe, laid in place complete, per lin. ft.	1.10
24-in. vitrified pipe, laid in place complete, per lin. ft.	2.00
30-in. vitrified pipe, laid in place complete, per lin. ft.	2.75
Relaying old pipe found in road, per lin. ft.	0.15
Steel beams, channels and structural shapes, spikes and nails, and cast iron, per lb.	0.05
Oak timber and plank, in place complete, per 1,000 ft. B. M.	40.00
Hemlock timber and plank, in place complete, per 1,000 ft. B. M.	30.00
Yellow pine timber and plank, in place complete, per 1,000 ft. B. M.	40.00
Guide boards, each	4.00
Road signs, each	4.00

Prices for the Following Items to Be Inserted by Bidder.

Broken stone macadam of the kind prescribed in these specifications, for bottom course, including filler, and rolled in place complete, per cu. yd.	—
Broken stone macadam of the kind prescribed in these specifications, for middle course, including binder, and rolled in place complete, per cu. yd.	—
Broken stone macadam of the kind prescribed in these specifications, for top course, including binder, and rolled in place complete, per cu. yd.	—
¾-in. broken stone of the kind prescribed in these specifications, in piles, loose measurement, per cu. yd.	—
Gravel or shale, rolled in place, per cu. yd.	—

ment or the steel reinforcement, which may be estimated at about \$3 additional. The average wages per 8-hour day for part of 1906 and for an 8-hour day for the remainder of the year were as follows:

Ordinary labor	\$1.75 to \$2.00
Crusher and roller engineers.....	2.00 to 2.50
Foreman	3.00 to 5.00
1-horse wagon and driver	3.00 to 4.00
2-horse wagon and driver	4.50 to 5.50

Contract Prices for Road Work in Massachusetts.*—The following averages of contract prices on state road work during 1907 have been taken from the 15th annual report of the Massachusetts Highway Commission. The prices are the averages for 64 contracts:

Excavation, all kinds, per cu. yd.....	\$0.52
Borrow, per cu. yd.....	0.64
Ledge rock excavation, per cu. yd.....	1.95
Concrete masonry, per cu. yd.....	9.34
Shaping, per sq. yd.....	0.93
Broken stone, local, per ton, in place...	1.64
Broken stone, traprock, per ton, in place.....	2.30

Pipe culverts, per lin. ft.:

12-in. vitrified clay, in place.....	0.80
18-in. vitrified clay, in place	1.66
12-in. iron, in place.....	2.34
18-in. iron, in place	2.57
Fencing, per lin. ft.	0.30

Ledge excavation covers only such ledge rock as requires blasting for its removal, and boulders of $\frac{1}{2}$ cu. yd. or more in volume. Concrete masonry is composed of 1 part Portland cement, 3 parts sand and 5 parts broken stone or gravel. For the pipe culverts nothing but selected fine material, free from large stone, shall be placed under and about the pipe, and all material under and about the pipe shall be tamped in place by a thin tamping bar. Fencing consists of chestnut or cedar posts not less than 6 ins. in diameter spaced 8 ft. apart and set 3 ft. in the ground and $2\frac{1}{2}$ ft. above. The top rail is 4 ins. square and the side rail of 2x6-in. spruce.

Wages in Massachusetts in 1907, per 8-hour day, were about as follows: Common labor, \$1.75 to \$2.35; team with driver, \$4.50 to \$5.

Per Cent of Engineering for Road Construction.†—During 1905 and 1906 there were built in New Castle County, Delaware, 7.43 miles of macadam road and 2.9 miles of gravel road. The per cent of engineering expenses on these roads varied from 2 per cent to 3.7 per cent, the average being 2.2 per cent.

In Madison County, Tennessee, $24\frac{1}{4}$ miles of macadam roads were built at a cost of \$115,581.71. The cost of engineering, superintendence and surveys was \$7,016.35, or about 6 per cent of the total amount expended.

In Pennsylvania the average cost of inspection on roads built for the State Highway Department has been 3 per cent of the cost

*Engineering-Contracting, Aug. 26, 1908.

†Engineering-Contracting, Sept. 23, 1908, and Apr. 28, 1909.

of the road and the average of engineering expenses has been 2 per cent, or a total of 5%.

In New Jersey, during 1908, a total of 146 miles macadam and gravel roads were built. Engineering and inspection averaged about 5.7%, of which 3.2% was for engineering and 2.5% for supervisor's salary, the supervisor being appointed by each county to oversee and direct the work.

Cost of Macadam Roads, New Jersey.—The following is a very brief summary of a table of quantities and bidding prices for 47 different macadam, gravel and Telford roads, which was given in *Engineering-Contracting*, April 28, 1909. There were 146 miles of these New Jersey state roads built in 1908, the following being about the average cost of a macadam road 6 ins. thick (after rolling) and 14 ft. wide:

	Per mile.
2,210 sq. yds. macadam at 65 cts.....	\$5,297
4,100 cu. yds. earth excav. at 34 cts.....	1,394
Engineering (3.2%)	214
Supervisor's salary (2.5%)	167
Total	\$7,112

About as many roads were built 8 ins. thick as 6 ins., at an added cost of about 20 cts. per sq. yd. for the 8-in. roads.

Cost of a Limestone Macadam Road, Buffalo, N. Y.—The following data apply to a limestone macadam road 6 ins. thick and 12 ft. wide, built by contract near Buffalo, N. Y., in 1898. The earth was a tough clay and ditches nearly 3 ft. deep were dug along both sides of the road. The cost of digging the ditches was nearly half the total cost of grading. The following was the cost of one mile of grading, including ditching and surfacing, in comparatively level country, the amount of excavation being about 4,600 cu. yds. (the graded road was 22 ft. wide between ditches):

Labor at \$1.50 per 10-hr. day.....	\$ 670
Teams at \$3.50 per 10-hr. day	326
Foreman at \$2.50 per 10-hr. day.....	97
Waterboy at \$1.00 per 10-hr. day.....	17

Total per mile **\$1,010**

This is equivalent to about 22 cts. per cu. yd.

There were stretches of this road where ditches already existed, and the only grading required was to plow up the old surface, shape the trench to receive the macadam, and make the earth shoulders 6 ft. wide on each side of the macadam. Such stretches of grading cost \$320 a mile.

The macadam was 6 ins. thick after rolling and 12 ft. wide. It was laid in two courses: (1) a foundation course of 1½ to 2½-in. limestone, 4 ins. thick after rolling; and (2) a top course of ¾ to 1½-in. limestone, 2 ins. thick after rolling. Both courses were bound with limestone screenings. As an average of 3¼ miles of road, it was found that loose stone spread to a depth of 6 ins. was rolled down with a 10-ton roller to an apparent thickness of 4 ins., but without doubt about 1 in. of stone was pushed into the subgrade and lost so far as the final measurement was con-

earned. It therefore took $1\frac{1}{2}$ cu. yds. of loose ($1\frac{1}{4}$ to $2\frac{1}{2}$ -in.) stone (measured in cars or wagons) to make 1 cu. yd. of rolled foundation course. For the top course it took a thickness of 2.8 ins. of loose ($\frac{3}{4}$ to $1\frac{1}{4}$ -in.) stone to give the required 2-in. thickness after rolling. This indicates also a further pushing of the foundation stone into the clay below, for all measurements of thickness were made with a level, and not by digging holes through the finished macadam. The average of these two courses was 1.46 cu. yds. of loose stone (not including screenings) to make 1 cu. yd. of rolled stone, but it took a trifle over $\frac{1}{2}$ cu. yd. of limestone screenings (from size of dust up to $\frac{1}{2}$ -in.) to bind each cubic yard of rolled macadam. We have, therefore:

Loose stone	1.46 cu. yds.
Screenings	0.34 cu. yd.
Total	1.80 cu. yds.

This means that it required 1.8 cu. yds. of screenings and loose stone (measured in wagons) to make 1 cu. yd. of rolled macadam. The cost of each cubic yard of macadam was as follows:

Stone and screenings, f. o. b., 1.8 cu. yds., at \$0.70.....	\$1.26
Freight, 25 cts. ton, 1.8 cu. yds., at \$0.28.....	0.50
Unloading cars into wagons, 1.8 cu. yds., at \$0.11.....	0.20
Hauling $\frac{1}{4}$ mile, 1.8 cu. yds., at \$0.28.....	0.50
Spreading, 1.8 cu. yds., at \$0.08.....	0.14
Sprinkling	0.19
Rolling, including rolling subgrade	0.24

Total per cu. yd. of macadam.....\$3.03

Laborers received \$1.50, and teams (with drivers) \$3.50 per 10-hr. day.

Cost of a Sandstone and Trap Macadam, Rochester, N. Y.—Near Rochester, N. Y., a macadam road 16 ft. wide and 6 ins. thick was built by contract, on a sandy soil. The bottom 4 ins. of the macadam were of sandstone bound with limestone screenings. The top 2 ins. were of trap rock bound with limestone screenings. The sandstone was fieldstone obtained mostly from old stone fences near the road. Wages of common laborers were 15 cts. an hour; teams, 35 cts.

The cost of sandstone crushed and delivered on the road was as follows per cubic yard measured in the wagons:

	Cu. yd.
Paid farmers for fences	\$0.10
Loading, hauling $\frac{1}{2}$ mile, and crushing.....	0.80
Hauling 1 mile and spreading.....	0.35
Total	\$1.25

The limestone screenings, used as a binder, were imported on canal boats, and delivered on the road cost as follows per cubic yard measured in the wagons.

	Cu. yd.
Screenings delivered on boats	\$1.60
Unloading into wagons with derrick.....	0.25
Hauling 2 miles	0.30
Spreading on road	0.15
Total	\$2.25

The cost of the trap rock was the same as for the limestone screenings. The cost of the 4-in. sandstone base was as follows:

	Cu. yd.
1.4 cu. yds. sandstone, at \$1.25.....	\$1.75
$\frac{1}{4}$ cu. yd. limestone screenings, at \$2.25.....	0.75
Rolling and sprinkling	0.08

Total (measured in place).....\$2.58

The cost of the 2-in. trap wearing coat was as follows:

1.4 cu. yds. trap, at \$2.25.....	\$3.15
$\frac{1}{4}$ cu. yd. screenings, at \$2.25.....	0.75
Rolling and sprinkling.....	0.52

Total (measured in place).....\$4.42

The 10-ton roller pushed much of the stone into the sandy subgrade, which accounts in part for the fact that it took 1.4 cu. yds. of loose stone to make 1 cu. yd. of rolled macadam. No very accurate record was kept of the amount of screenings used, but the amount stated is not far from correct. It will be noted that rolling the 4-in. lower course cost only 8 cts. per cu. yd. as compared with 52 cts. per cu. yd. for the 2-in. top course. This is due to the fact that the lower course was hastily rolled. Strictly speaking these two courses should not be treated separately in discussing the cost of rolling. The cost of rolling and sprinkling the two courses was 24 cts. per cu. yd.

Cost of Experimental Macadam Roads, Illinois.*—Mr. A. N. Johnson gives the following regarding 12 experimental macadam roads (13.76 miles) built in Illinois in 1907 and 1908. The work was done by day labor. Each road was made 12 ft. wide, and two layers of loose broken stone were laid to an aggregate depth of about 10 ins., which would be equivalent to a little more than 6 ins. of compacted macadam. Limestone, weighing about 2,500 lbs. per cu. yd., was used, costing about \$1.25 per cu. yd. on cars at the destination. The cost of 44,000 cu. yds. of loose broken stone was as follows per cubic yard (loose measure):

	Per cu. yd. (loose).	Per cent.
Labor.		
Unloading stone from car	\$0.10	10.1
Hauling stone	0.32	34.0
Spreading stone	0.08	8.5
Rolling and sprinkling	0.11	11.5
Total labor on stone	\$0.61	64.1
Excavation of earth	0.12	12.4
Shaping roadbed	0.08	8.3
Trimming shoulders	0.06	6.3
Supt., watchman and incidentals.....	0.09	9.9
Total labor	\$0.95	100.0
Stone, f. o. b. cars, say.....	1.25	
Grand total	\$2.20	

It is not stated whether interest and depreciation of steam roller are included, but apparently not. Average rates of wages are not given for these 44,000 cu. yds., but wages on 8 different jobs in

*Engineering-Contracting, Nov. 16, 1908.

1908 (involving 25,000 cu. yds. of stone) are given, and average \$2.10 per day; team (with driver) averaged \$4.20.

The 1½-in. size stone was used for the bottom layer, and the 3-in. stone, bonded with screenings, was used for the top layer, reversing the usual practice.

Irregular shipments of stone and bad weather caused delays that added considerably to the cost.

If the above given costs per cu. yd. of stone (loose measure) be multiplied by 0.3, the approximate cost per sq. yd. will be obtained.

The shaping of roadbed averaged 2.4 cts. per sq. yd. of macadam, although on one job it cost only 1.8 cts. although the wages were \$2.50 a day.

The trimming of shoulders cost 1.5 cts. per sq. yd. of macadam.

The total cost per mile of macadam road, 12 ft. wide, 10 ins. thick before compacting (about 5 ins. afterward), was about \$5,800, the haul of stone averaging 1 to 1½ miles.

Data on Depreciation and Repairs of Steam Road Rollers.*—Steam road rollers were first built in England about 1865, and it is to England that we naturally look for the most complete records of the cost of repairs and the life of these machines.

The English author, Thomas Aitken, has kept careful records for a period of more than 20 years, and his data are especially valuable not only to English but to American road builders.

Aitken gives the following table of first cost of English rollers:

15-ton roller, single cylinder.....	\$2,300
12-ton roller, single cylinder.....	2,000
10-ton roller, single cylinder.....	1,875

Aitken puts the life of a roller at not less than 25 years. He estimates 8,000 tons of stone consolidated by a 15-ton roller each year.

Aitken gives the following cost of repairs on a 15-ton roller, which he regards as typical:

"Up to the fourteenth year the repairs were comparatively trifling, with the exception of a pair of new driving wheels and repairing the fire-box and tubes, etc. These latter, and including sundry repairs, amounted, on an average, to \$55 per annum. It was then found necessary to have a new fire-box and general overhaul of all the working parts. This cost \$850, and the engine should, it is anticipated, be capable, with ordinary repairs, to run for a period equal to a life of 25 years at least."

Aitken puts the total cost of renewals and repairs of a \$2,300 roller at \$105 a year during a life of 25 years, which is nearly 5 per cent of the first cost each year. To this must be added a percentage to cover depreciation, that is to provide a sinking fund sufficient to buy a new roller at the end of 25 years. If such a sinking fund draws 3 per cent compound interest, it requires that about 2.75

**Engineering-Contracting*, April 7, 1909.

per cent of the first cost of the roller be set aside annually to amount to the full first cost of the roller in 25 years. This 2.75 per cent depreciation fund allowance if added to the 5 per cent for repairs and renewals, gives a total of nearly 8 per cent per annum.

Aitken says that this is equivalent to 82 cts. per working day. Since 8 per cent of \$2,200 is \$184, if we divide the \$184 by \$0.82, we find that Aitken apparently figures on 221 working days in the year, which is almost double the number of days commonly worked by a roller in the northern part of the United States. (See *Engineering-Contracting*, May 23, 1906, July 3, 1907 (p. 7), June 10, 1908 (p. 358), for data as to the number of days worked in Massachusetts, and the cost of roller repairs.) Aitkin says that his estimate relates to a roller used in macadam repair work, "practically in steam all the year, except when under repairs or stopped by frost during winter months."

There is a seeming discrepancy in his figures, for he rates a 16-ton roller as capable of compacting at least 64 tons of macadam per day of 8 hours, if not interfered with by traffic. Elsewhere he estimates the "useful effect of one roller at 8,000 tons of macadam per annum," from which it would appear that less than 150 full days would be worked, or that delays due to traffic would cause a serious loss of time.

The writer's experience is that 75 tons of macadam can be compacted per 10-hour day, and that a contractor can usually count on about 100 to 110 days' actual work, which gives a total of some 8,000 tons (including screenings) compacted each season by a 10-ton roller.

Regarding the repairing of the driving wheels, Aitken says:

"The renewal of the driving and front wheels, especially the former, is an expensive item, and what was considered at one time impracticable can now be carried out, that is, plating the worn-out rims. This results in considerable saving, and the wear of the metal forming the rims is considerably less than in the original wheels. It should be stated, however, that the wheels for renewal of rims should not be worn too thin, as, in such cases, the renewal is not so satisfactory. The process is to fit steel plates on the old rims and rivet the two together, and, apart from a few of these becoming loose, which can be remedied by counter-sunk bolts, the arrangement is in every way successful. The gripe or 'bite' of these steel-plated wheels is as good as that of the original cast-iron ones, and the wear is much more uniform."

Aitken goes on to state that the wear of these steel-plated rims is 0.02 in. for every 1,000 tons of macadam consolidated, and that the cost of repairing the driving wheels by this method is \$200 as against \$250 for a complete set of new wheels, and that "experience shows that the life of those renewed with steel plates is nearly doubled."

There seems to be enough merit in this method of repairing the driving wheels to warrant the manufacturer's making them with removable steel plate rims in the first place. If the plates were of

manganese steel the life would probably be three to four times as long as when made of ordinary steel.

Aitken states the cast-iron driving wheels of a 15-ton roller lasted 7 years, during which time they consolidated 60,000 tons of macadam.

Cost of Road Roller Repairs in Massachusetts During 1906.*—The Massachusetts Highway Commission had under its control 18 steam road rollers. The rollers were used 1,126½ days on town work, in 22 different towns. They were also used 557½ days on state highway repair work, on 65 different roads; 290 days by towns contracting for the building of state roads, including the small town roads; 162 days by private contractors on state highway contracts, and one roller was used eight days at the State Farm at Bridgewater. The total number of days' work during the year was 2,144—an average of 119 days for each roller. The total cost of such maintenance for the year was \$2,046. Of this amount \$1,000 was paid for practically rebuilding one of the rollers which had been in active use since 1898; and \$1,046 was expended for the ordinary repairs. Including the expense of supervision and inspection of the rollers, the average cost of such ordinary repairs during 1906 was 90 3 cts. per day for each roller in use. A comparison of the above figures with those of the years 1906 and 1907 is given below:

	1906.	1907.	1908.
Number of rollers.....	16	16	18
Total days worked	1,719½	1,808	2,144
Av. days per roller.....	107½	113	119
Av. cost ordinary repairs per roller day.....	\$0.98½	\$0.99½	\$0.90 4/5

In *Engineering-Contracting*, May 23, 1906, it is stated the Massachusetts Highway Commission had 16 rollers during 1905, that they averaged 90 3 days worked per roller, and that the cost of ordinary repairs was \$1.12 per roller per day worked.

Cost of Scarifying Macadam By Hand.—Mr. Thomas Aitken is authority for the following English data:

When a macadam surface is to be picked, or scarified, by hand, soak the crust with water to soften it, unless it is the intention to screen the old materials. The depth to which the macadam is loosened by picks is usually about 2½ ins. One man will loosen at the following rate per day:

	Sq. yds.
Soft macadam	33
Hard macadam	20
Very hard (steam rolled) macadam.....	12 to 15

Cost of Scarifying With a Machine.—A scarifier is a heavy harrow for ripping up old macadam preparatory to resurfacing it. See Fig. 3.

A scarifier is pulled by a steam roller, and it usually requires two men to operate the scarifier. According to Thomas Aitken, a scarifier with 3 teeth, spaced 6 ins. apart, will break up old macadam

* *Engineering-Contracting*, May 5, 1906.

to a depth of 4 ins. at the rate of 3,000 sq. yda. per 10-hr. day, if not interrupted by traffic. He gives one record of 650 cu. yda. per hr., scarified to a depth of 2 ins., using a 15-ton roller to pull it. But, allowing for interruptions from traffic that ordinarily occur on a country road, he gives 1,500 to 2,000 sq. yda. per 10-hr. day.

He states that each set of teeth will scarify only 150 sq. yda. before requiring sharpening, and that it costs 15 to 30 cts. to sharpen the set of 3 teeth, at which rate it costs 0.1 to 0.2 ct. per sq. yd. for sharpening the teeth. This would give a cost of \$3 to \$6 per day for sharpening teeth where 3,000 sq. yda. are scarified daily.

The following paragraph gives some American data.

Cost of Scarifying Macadam, Rhode Island.*—In breaking up the crust of an old macadam road preparatory to mixing it with tar or asphaltic oil, a scarifier drawn by a steam roller is cheaper than the use of "picks" in the rear wheels of the roller.

Fig. 3. Scarifier.

This is well illustrated by the following costs of scarifying which have been furnished to us by Mr. Arthur H. Blanchard, assistant engineer of the State Board of Public Roads, Providence, R. I.

An old macadam road at Tiverton, R. I., was scarified to a depth of 2 or 4 ins. at a cost of 0.7 ct. per sq. yd. The steam roller and scarifier were rented. The price paid for the steam roller, including fuel and wages of engineman, was \$10 per day of 10 hours, which is a reasonable price. The price paid for the use of the scarifier was \$5 a day, which is reasonable when due allowance is made for the cost of sharpening its teeth. Two laborers, at \$2.50 each per

**Engineering-Contracting*, Oct. 28, 1908.

10-hour day, operated the scarifier. Therefore the daily cost was as follows:

	Per day.
Roller, including engineman.....	\$10.00
Scarifier	5.00
2 laborers, at \$2.50.....	5.00
Total	\$20.00

The average 10-hr. day's work was 2,738 sq. yds. scarified, hence the cost per square yard was:

	Cts. per sq. yd.
Roller, including engineman.....	\$0.36
Scarifier	0.18
Laborers	0.18
Total	\$0.72

It may be well to add that the practice of using "picks" in the rear wheels of a steam roller is not to be commended, for the resulting shocks to the whole machine, and particularly to the boiler, are injurious. Boiler tubes quickly become loosened and leak badly under this severe service, if the picks are used in the roller for a considerable length of time.

Cost of Resurfacing Old Limestone Macadam.—The data were taken from my time books and can be relied upon as being well within the probable cost of similar work done by contract under a good foreman. It will be noted that the cost of operating the roller is estimated at \$10 per day. This includes interest and depreciation, as well as fuel and engineman's wages.

The road was worn unevenly, but as it still had sufficient metal left, very little new metal was added.

The roller used was a 12-ton Buffalo Pitts, provided with steel picks on the rear wheels. It required 80 hours of rolling with the picks in to break up the crust of a surface 19,400 sq. yds. in area, 2,400 sq. yds. being loosened per 10-hr. day. The crust was exceedingly hard and at times the picks rode upon the surface without sinking in, so that a lighter roller would probably have been far less efficient. In fact a 10-ton roller had been used a few years previous for the same purpose at more than double the expense per sq. yd., I am told. The picks simply open up cracks in the crust to a depth of about 4 ins. and it is necessary to follow the roller with a gang of laborers using hand picks to complete the loosening process. The labor of loosening and spreading anew the metal was 1,880 man-hours, or a trifle more than 10 sq. yds. per man-hour. About 60% of this time was spent in picking and 40% in resspreading with shovels and potato hooks.

After the material had been resspread, a short section was drenched with a sprinkling cart, water being put on in such abundance that when the roller came upon the metal, the screenings which had settled to the bottom in the spreading process were floated up into the interstices. The roller and sprinkling cart were engaged only 63 hours in this process, 3,000 sq. yds. being rolled per 10-hr. day; an exceptionally fast rate. The rapidity of rolling was

due to four factors: 1. The great abundance of water used, the water haul being very short. 2. The unyielding foundation (Telford) beneath. 3. The abundance of screenings and fine dust, the road not having been swept for some time. 4. The great weight of the roller, which was run at a high rate of speed. I am not prepared to say that longer rolling would not have secured a harder surface, but I doubt very much whether it would. The metal, I should add, was hard limestone. Summing up we find the cost of resurfacing this road per sq. yd. to have been as follows:

	Cts., per sq. yd.
Picking with roller, at \$1 per hour.....	0.40
Picking by hand labor at 20 cts. per hour.....	1.20
Respreading by hand labor, at 20 cts. per hour....	0.80
Rolling with roller, at \$1 per hour.....	0.33
Sprinkling with cart, at 40 cts. per hour.....	0.13
Foreman, 143 hours, at 30 cts., for 19,400 sq. yds..	0.44
Total	3.30

At this rate a macadam road 16 ft. wide can be resurfaced for little more than \$300 a mile. The frequency with which such resurfacing is necessary will, of course, depend upon several factors, chief of which are the amount of traffic and the quality of road metal. I should say that five years would not be far from the average for a country road built of hard limestone. Unless the road has had an excess of metal used in its construction, new metal should be added at the time of resurfacing to replace that worn out.

I am unable to see how any system of continuous repair, with its pattering work here and there, can be as economical as work done in the manner above described. I would not be understood, however, as favoring an entire neglect of the road between repair periods. At times of heavy rains and snows, ditches and culverts need attention and there should be someone whose duty it is to look after such matters. What I do question is the economy of having a man continuously at work putting in patches upon the road.

Low as the above costs are, much lower costs are attainable, using a scarifier, as previously described, or using a harrow, as described in the next paragraph.

Cost of Repairing Sandstone Macadam, Albion, N. Y.—Using the method that I am about to describe, Mr. P. J. Stock succeeded in picking, resurfacing and rolling a stretch of sandstone macadam 16 ft. wide by 1,000 ft. long in two 10-hr. days; one day in spiking up the old surface with the picks in the steam roller and one day in rerolling. As the surface was loosened to a depth of about 4 ins., it will be seen that over 200 cu. yds., or 1,800 sq. yds., of macadam were compacted by the 15-ton roller in 10 hrs. The point to which I wish to call attention is not so much the extraordinary rapidity of the rolling as the very ingenious method devised by Mr. Stock for completing the loosening of the macadam after cracking it up with the roller spikes. For this purpose Mr. Stock built a heavy harrow,

similar to those used on farms, Fig. 4, showing its detail design. By turning the harrow upside down it rides on the runners shown in the figure, and is thus transported when not in use. A heavy team of horses is used to drag the sharp-pointed harrow over the macadam after it has been loosened as much as possible with the spikes of the steam roller. The spikes in the harrow not only com-

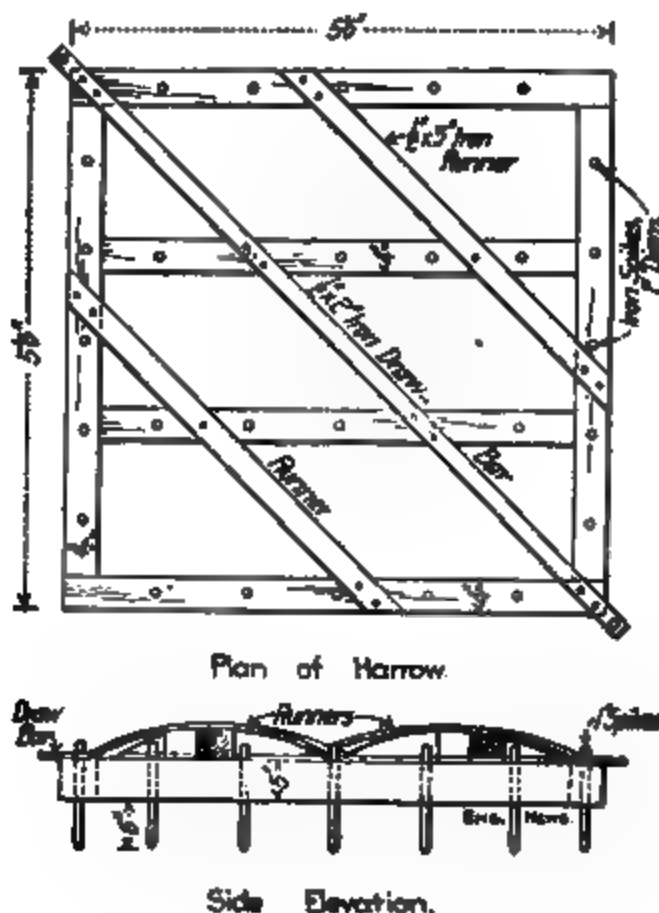

Fig. 4. Harrow for Scarifying.

plete the breaking-up of the crust as well as could be done by men using picks, but in addition the spikes spread the loosened stone, filling up all low places.

The total cost of resurfacing was:

	Cts., per sq. yd.
Roller and engineer at \$1 per hour picking.....	0.5
Roller and engineer at \$1 per hour re-rolling.....	0.5
Sprinkling, with cart, 40 cts. an hour (1 day)....	0.2
Harrowing, team and driver 30 cts. an hr. (2 days)	0.3
Total	1.5

At this rate a macadam road 16 ft. wide and a mile long can be resurfaced for less than \$140. The cost of resurfacing has, there-

fore, been only \$30 per mile per annum, since resurfacing has been necessary only once every 5 yrs.

It will be noted that the cost of picking (with roller) and harrowing was 0.8 ct. per sq. yd.

In addition to the labor item there were some 75 cu. yds. of stone furnished, which it was estimated would bring the road up to its original crown. The stone cost about \$60, delivered, and was spread by two men in two days at a cost of \$6. By using a "leveler" the item of spreading could have been reduced to \$1.50.

For new materials we have, therefore, a trifle over \$60 per mile per annum, making a total of about \$90 per mile per annum for labor and material for resurfacing a Medina sandstone road. Of course, the loss of material by wear was not accurately measured, but it was less rather than more than the amount put on for repairs. At this rate, the annual vertical wear was about 0.2-in. over the whole surface.

This was a main traveled street, where farmers' teams enter the village.

Cost of Resurfacing Macadam and Data on Compression of Broken Stone.—Mr. F. G. Cudworth gives the following data. An old macadam road was resurfaced with trap rock to the depth of 3 ins. after rolling with a 10-ton steam roller. It required 3.9 ins. of loose trap and 2.1 ins. of screenings to make the 3 ins. of compacted macadam, according to Mr. Cudworth, but there must have been an error in his estimate of the final thickness of the resurfacing (and it is a very easy matter to err in measuring rolled macadam). Possibly he did not measure the thickness of loose screenings left on the macadam, for 2.1 ins. of screenings is more than sufficient to fill the voids in 3 ins. of compacted stone. The steam roller averaged 472 sq. yds. or 40 cu. yds. of macadam per 10 hrs., at a cost of 2½ cts. per sq. yd. for rolling and sprinkling. The cost of rolling and sprinkling was distributed as follows, and it should be noted that it does not include any allowance for rent of roller. On the other hand it is rare that a fireman is employed in addition to the engineman, and it is not always that the full wages of a night watchman are charged to the roller:

Engineman	\$ 3.00
Fireman	1.50
Coal and oil	4.00
Sprinkler	3.00
Watchman	1.50

Total per day.....\$13.00

The total cost of resurfacing was as follows, not including cost of stone:

	Cts. per sq. yd.
Scraping and sweeping	2.00
Picking up old surface.....	1.50
Spreading stone	2.00
Rolling and sprinkling.....	2.77
Total per sq. yd.....	8.27

As will be seen by comparison with data previously given, this

cost of 3.27 cts. per sq. yd. is inordinately high, and shows both lack of good management and of knowledge of how to do such work economically.

Mr. W. C. Foster gives the following data: It was found that 7.38 ins. of loose trap rock on an old macadam pavement were rolled down to a thickness of 6 ins. under a 12-ton roller, a ratio of $1\frac{1}{4}$ cu. yds. of loose stone to 1 cu. yd. rolled. It was found in another case that 5.67 ins. of loose trap were rolled down to 4 ins., a ratio 1.42 to 1. The stone in both cases was trap, $1\frac{1}{2}$ to $2\frac{1}{4}$ -in. size. It was found that 1 cu. yd. of blue limestone screenings, sufficient to cover the rolled trap to a depth of 1.7 ins. over 21 sq. yds., was sufficient to bind 21 sq. yds. of 4-in. or 6-in. macadam. The loose stone and the screenings were measured in cars. I do not think that 5.67 ins. of loose trap can possibly be rolled down to 4 ins., furthermore I am sure that it takes more screenings to bind a 6-in. macadam than a 4-in. macadam. Mr. Foster says that in this work a 12-ton roller averaged 314 sq. yds., or 53 cu. yds., of 6-in. macadam per 10-hr. day.

Cost of Repairing Macadam in Ireland.—In *Engineering-Contracting*, Sept. 2, 1908, there is an excellent article on the methods of scarifying and rolling macadam roads in Ireland, also some costs, by Mr. H. A. Hackett. A brief abstract of the costs is as follows:

Common laborers, per day.....	\$0.52
Foremen, per week.....	4.00
One horse cart and driver, per day.....	1.25
Engineman on roller, per day.....	1.35
Flagman and timekeeper, per day.....	0.87

Coal costs \$5.50 per long ton at the railway station, and a 15-ton roller consumes one-third ton per day.

Mr. Hackett states that in Tipperary county there are 1,500 miles of macadam roads, of which 300 miles are main roads. The population is 90,000, and the area of the county is 1,000 sq. miles. The traffic is not severe, practically all in one horse carts carrying loads of 1 to $1\frac{1}{4}$ tons on a pair of wheels.

From his data it can be deduced that the cost of repairing a macadam road 16 ft. wide is about \$280 per mile per annum, there being 0.12 cu. yd. of broken stone used per sq. yd. of road for each resurfacing every five years, which is equivalent to 1,120 cu. yds. of stone per mile every five years, or 224 cu. yds. per mile per annum. Since the steam roller averaged about 50 cu. yds. of loose stone compacted per day, it is a simple matter to estimate the cost of such repairs under American conditions as to wages.

All the stone was quarried and broken by hand, and the following was the cost per cu. yd. loose measure, wages being as above given:

	Per cu. yd.
Surface damage to quarries.....	\$0.04
Quarrying and breaking.....	0.46
Hauling.....	0.15
Spreading, watering and sweeping.....	0.12
Recarting stones, removing scarified materials....	0.10
Rolling.....	0.17
Contingencies and profit.....	0.10
Total	\$1.14

It is noteworthy that, in spite of the fact that wages were about one-third what they are in America, the unit cost of this work is almost as great as it is in America.

Mr. Hackett is strongly in favor of this intermittent system of repairs, instead of the old continuous or "patching system." He is also in favor of a 15-ton roller, and states that it will do 50% more work than a 10-ton roller, due to its wider tires.

Cost of Maintaining Macadam Roads, Massachusetts.—The annual reports of the Massachusetts Highway Commission show that the cost of "ordinary repairs" of macadam roads, whose age ranges from 1 to 15 years, averages about \$100 per mile per year, excluding the cost of resurfacing. A small per cent of the macadam roads are now being resurfaced annually, this work being classed as extraordinary repairs. From data thus far obtained it is estimated that the maximum cost of all repairs—ordinary and extraordinary—will not exceed \$200 per mile, unless the destruction occasioned by automobiles shall materially increase the cost of maintenance. The standard Massachusetts road is macadamized 15 ft. wide.

Cost of Repairing Macadam in Massachusetts.—The repairing on 550 miles of macadam roads averaged less than \$100 per mile for the year 1904, although the first of these roads was 10 years old. But this does not include any general resurfacing.

In the report for 1902 data on the cost of repairing three heavily traveled roads leading into cities are given.

Road.	Age, yrs.	Length.	Width.	Per sq. yd. per year, cts.	Tons stone per sq. yd. per yr.	Cost per ton in place.
Leicester	6	3,150	24	5.17	.03	\$1.70
West Fitchburg..	7	2,200	16	5.15	.023	2.23
Beverly	6	2,150	18	5.26	.03	1.80

None of these roads had been repaired since the day it was built. The Leicester road leads into Worcester, and is much more heavily traveled than ordinary country roads.

During 1906 the commission caused to be repaired 580.7 miles of roads, the average cost being \$96.07 per mile.

A total of 13½ miles of road was resurfaced with broken stone; the cost of doing this is shown in the table below.

In Table III it is assumed that a cubic yard of stone weighs 1½ tons, and that the loose broken stone shrinks 22 per cent under the compacting force of the roller.

The high rate of wear shown in Auburn and Hadley is due to strengthening the road, when resurfacing, by an increased depth of broken stone; the high rate of wear in Quincy and Chelsea is due to heavy traffic; in Sturbridge, to a poor grade of stone used in the original construction. In the case of Marion and Rochester, the original road was macadamized by those towns in 1896. In Hadley, \$932 was used for side drains and in strengthening the road.

TABLE III.—COSTS OF RESURFACING 14 MACADAM ROADS DURING 1903.

Town or City.	Year of Lay-out.	Length (Feet)	Width (Feet)	Broken stone per Square Yard per Year (Tons)	Per Square Yard per Year (Cts.).	Broken Stone in Place, per Ton.
Auburn*	'95-6-7	10,168	16	.03	5.62	\$1.49
Chicopee†	'97-8-9	3,550	15	.02	4.40	2.04
Chelsea†	'01	3,053	24	.11	12.32	1.60
Beverly†	'95	3,025	18	.01	3.22	2.09
Great Barrington†	'94-6	9,368	16	.01	2.47	2.24
Hadley†	'94	2,788	15	.04	9.29	1.78
Marion*	'93	782	15	.01	2.98	1.75

Sturbridge*	'97	3,094	15	.03	4.85	1.50
Quincy†	'99	2,806	30	.03	7.09	2.20
Rochester*	'03	3,345	15	.02	4.17	1.75
Townsend†	'96-7-8	3,700	15	.01	3.31	1.91
Westport†	'94	3,016	18	.02	5.19	2.35

*Local stone used.

†Trap rock used.

Cost of Calcium Chloride as a Dust Preventative.*—During the summer of 1907, the U. S. Office of Public Roads undertook a series of tests to determine the value of calcium chloride as a dust preventative. These tests were made on the portion of the macadam driveway in the Agricultural Department Grounds, in Washington, D. C.

The roadway on which the test was made is built of trap rock, held in position by a soft limestone binder. The screenings of this binder pulverized rapidly under traffic, forming a light dust which passing vehicles continually raised into the air. It was then carried away by the wind. In this way the road was becoming stripped of its binding material.

In preparation for the treatment all dust, and dirt were scraped from the surface of the roadway. A solution was prepared by mixing 300 lbs. of commercial calcium chloride (granular, containing 75 per cent calcium chloride and 25 per cent moisture) with 300 gals. of water in an ordinary street sprinkler, care being taken to agitate the liquid thoroughly before applying it to insure a uniform solution. It was then applied from one sprinkling head, and the sprinkler passed slowly back and forth over the road to facilitate the complete absorption of the solution. Each application consisted of 600 gals. over an area of 1,582 sq. yds., or 0.38 per sq. yd.

The first application was made July 13, 1907, followed by a similar one July 15, to increase the efficacy of the treatment. The effect of the first two treatments was marked. No auxiliary sprinkling was necessary for some time, the light rains falling at intervals

*Engineering-Contracting, July 1, 1908.

supplying all the moisture required. The untreated portions of the driveway lying parallel to 12th and 14th streets, were sprinkled daily and vehicles raised a perceptible dust, although the traffic over these wings was much less heavy than that on the treated portions.

During this time the appearance of the roadway varied perceptibly in color according to the moisture in the road surface, ranging from a light gray when dry to a peculiar grayish brown when moist. The brown shades were deepest over the portions traversed by the wheels of vehicles. The texture of the road surface was completely changed after the application of the calcium chloride. Before treatment, raveling was excessive in spots and the whole surface seemed loosely knit together. After the application on July 15 this condition changed and the road surface became smooth, compact and resilient.

The third treatment was given Aug. 3, as certain points exposed to the most severe wear were showing signs of raveling. The phenomena following this treatment were not unlike those attending the first set of applications and repeated themselves as later applications were made, though no further treatments were given until the condition of the roadway seemed to demand it. Such auxiliary sprinkling as was necessary consisted in the application of about 0.2 gal. of water per square yard at a time.

The accompanying table shows the cost of applications. The calcium was donated by a manufacturing chemical company of Baltimore, Md., and is charged at the rate of \$16 per ton, f. o. b. cars at Baltimore. A freight charge of 13 cts. per hundredweight is added to place the material on the ground. This makes the total cost of the calcium chloride \$18.60 per ton.

	Total	Per sq. yd.
300 lbs. calcium chloride	\$5.586	\$0.00352
2 men, 1½ hours.....	0.675	.00042
1 horse sprinkling wagon, 1½ hours.....	0.525	.00023
Total (1,682 sq. yda.).....	\$6.786	\$0.00427

Total cost of five applications was \$22.90, or \$0.0235 per square yard. Labor was paid 15 cts. per hour and 25 cts. per hour was paid for the sprinkling wagon.

The specific gravity of these solutions ranged from 1.053 to 1.066. Some variation was unavoidable, as the calcium chloride in some of the barrels had absorbed a large amount of moisture from the atmosphere. In such cases the actual percentage of the chemical to 300 lbs. was less than where little or no moisture had been absorbed.

At the time of the last application several hundred pounds of the salt remained unused. This was divided as nearly as possible into two parts, to be applied to the two wings of the driveway lying parallel to 12th and 14th streets. The east wing received a treatment of 0.23 gal. per sq. yd. of a solution the specific gravity of which was 1.145 and the west wing a similar application of a solution having a specific gravity of 1.121. No further sprinkling was

found necessary for the remainder of the season upon these branches of the main driveway.

Cost of Tarring Macadam, Michigan.*—Mr. Charles R. Wrightman gives the following relative to 18,620 sq. yds. of work done in South Haven, Mich.

The local gas company furnished the tar. The plant consisted of a roofer's tar kettle which held about 150 gals. of tar; six galvanized sprinkling cans, each of which held 14 quarts; the sprinklers were removed and a flat spout with $\frac{1}{8}$ -in. opening 6 ins. long, put in place of the sprinklers; one dozen fiber stable brooms.

The kettle was set up about midway in the first block of Center street, which was a new macadam street, 50 ft. wide, from which travel had been excluded, and which had been allowed ten days to dry.

Two barrels of tar were placed in the kettle and brought to the boiling point, then it was drawn into the sprinklers, Fig. 5, two of which were carried by each of three men and poured with a

Fig. 5. Tar Spreader and Curb Protector.

sweeping motion from side to side, each man covering about one-third of the width of the street, thus carrying a straight face of tar up the street. Working on the tarred surface and closely following the sprinklers, was a man with a fiber broom who smoothed out the thick spots and rubbed the tar in wherever dust or depression prevented a good contact. Immediately following, came two men, who with scoops, uniformly covered the tar with limestone screenings or "crushed stone sand" to the depth of from $\frac{1}{2}$ in. to $\frac{3}{4}$ in., which was then immediately rolled with a 10-ton steam roller (weight not essential), and the street then thrown open to traffic.

The results of this work are that the street is free from stone dust and is dry in an incredibly short time after rain, and I have

**Engineering-Contracting*, May 8, 1907.

noticed that snow melts and runs off much faster than it does on brick streets and that a few hours of thaw clears the street so there is nothing to freeze when night and a lower temperature comes on. We now treat the macadam before throwing it open to traffic, as we found on Dyckman avenue, which had been in use about three months, that the mud and dirt interfered seriously and we did not get as good adhesions on this street. In this case the surface was first swept clean with steel brooms and all spots of scale or droppings, scraped off with a scraper made by straightening the shank of a garden hoe until the blade was in line with the handle. While it was a decided improvement to this street, the results were not as satisfactory as on the new surfaces, and, if possible, I would break up and remetal a street before applying tar.

In heating, we found it best to put tar into the kettle with buckets about as fast as it was drawn off into the spreading cans, thus doing away with the necessity of spreaders waiting for "hot stuff." The kettle should be on wheels so that it could be moved without drawing off the tar and extinguishing the fire, as was necessary with the kettle which we used.

On about 1,000 sq. yds. of the work, torpedo sand was used for surfacing in place of limestone screenings. The results were favorable but not as satisfactory as when screenings were used, it being found that it was very hard to get the sand dry enough properly to take up the free tar; but I believe if good, sharp torpedo sand, free from moisture, could be obtained, the results would be satisfactory.

The unrefined tar which was used on this work is a very active irritant and will draw a blister in short order. In order to obviate this, men handling tar should keep their hands and faces well smeared with fresh lard. On the above work, we used about 15 lbs.

In order to keep from smearing the curb stone with tar, I had made two sheet iron guards, Fig. 5, taking a piece of heavy galvanized iron, 16 ins. wide and 8 ft. long, bent in the middle to a right angle and provided with a strap handle on top. This was laid on the curb with one leg of the angle perpendicular and against the face of the curb, the other lying on and projecting over the top. The spreaders moved it along each time a can full of tar was spread. This eliminated the unsightly splotches.

Some judgment has to be exercised on the work of spreading tar. Apply more where the surface is open or not "puttied," and less where surface is hard and close. Good intelligent men should be employed as spreaders as much of the economy in tar is dependent on them. Too much screenings is preferable to too little, and, after rolling, the surplus may be swept up and used again.

A close watch must be kept on the kettle as unrefined tar is highly inflammable, and, after it starts to boil, will climb over the top of the kettle very quickly. In case of fire, sand should be thrown into the kettle until the fire is smothered.

The gang was as follows per day of 10 hrs.:

	Per day.
1 kettleman (acts as foreman).....	\$ 2.25
2 barrel men, at \$2.25.....	4.50
3 men sprinkling tar, at \$2.25.....	6.75
1 man brooming tar, at \$1.75.....	1.75
3 men spreading screenings, at \$1.75.....	5.25
1 team hauling tar and screenings.....	3.50
Total	\$22.25

The team hauled tar, wood and screenings and moved kettle from place to place. At times it became necessary to put on an extra team to keep the work supplied with screenings, but ordinarily one team took care of the whole work.

This gang averaged about 1,500 sq. yds. (700 gals. tar) per day, and the cost was as follows:

Labor:	Per sq. yd.
Kettleman	\$0.0015
Barrelmen	0.0020
Men sprinkling tar.....	0.0045
Man brooming tar.....	0.0012
Men spreading screenings.....	0.0023
Team	0.0023
Total labor	\$0.0148
Materials:	
0.466 gals. tar, at 3 cts.....	\$0.0140
0.0175 cu. yd. screenings, at 90 cts.....	0.0158
Total materials	\$0.0298
Grand total	\$0.0446

In addition to the above, the city roller was used a total of 15 hrs., and, if we assume \$1 per hr. for the roller, the cost of rolling was less than 0.1 ct. per sq. yd., which, added to the above 4.5 cts., gives a total of 4.6 cts.

With a portable kettle, a saving of 20 per cent on labor would have been effected, by doing away with the time lost by all hands in moving the kettle.

Being so well pleased with tar on macadam, Mayor C. E. Abell authorized an experiment on clay. Accordingly, Chambers street, which is a porous yellow clay street, having a width of 40 ft. between wood curbs, was shaped up with a road grader, making a crown of about 20 ins. and rolled with the 10-ton steam roller. Tar and screenings were applied in the same manner as on the macadam streets, and the results have been surprising. This street, which has been practically impassable every spring and fall, is now perfectly dry and smooth, and a passerby would suppose it was macadamized. In two or three places where light, uncompacted dust was on the surface, the tar and stone covering has been broken, but otherwise it is in perfect condition, shedding the water nicely, and bids fair to be a good hard road for some time. The cost of the tar and stone was practically the same as on macadam, but in doing this work, we have learned that the preparation is the essential point. The road should be shaped and carefully smoothed by rolling and wetting until no loose or dry powdered clay remains; and, just the reverse

from macadam which must be perfectly dry, the clay should be slightly moist, as the hot tar on dry, powdered clay rolls up into minute balls and does not spread out as it should in a film or sheet. In every instance, the tar should be as near the boiling point as possible, when applied to the street.

Cost of Tarring Macadam, Massachusetts.*—The following data relate to some experimental road treatments made last year by the Metropolitan Park Commission on roadways at Revere Beach Parkway, Massachusetts. The experiments were made with a specially prepared coal tar known as Tarvia, and a total length of $3\frac{1}{2}$ miles of roadway was treated with this material, the work being done by day labor under the supervision of the Engineering Department of the commission. The work was begun Aug. 25, 1906, and was completed Sept. 29, a total of 67,434 sq. yds. of roadway having been treated at a cost of \$4,494.

The force employed consisted of one foreman and seven laborers. A street sweeper, a sand sprinkler, a double team and one steam roller were used in the work.

The Tarvia was delivered in tank wagons, and the cost of hauling same was paid by the commission. The same men were used for the various operations of cleaning the road, spreading the Tarvia and covering with screenings. The detailed costs of the work are given by Mr. John R. Rablin as follows:

Materials:	Per sq. yd.
Tarvia, 0.4 gal.....	\$0.0262
Stone screenings, 0.016 tons.....	0.0184
Total materials	\$0.0446
Labor:	
Preparing roadway	\$0.0086
Applying Tarvia	0.0057
Applying screenings	0.0063
Rolling	0.0047
Total	\$0.0252
Grand total	\$0.0698

Thus a new smooth surface was formed over the bare stone, which seems to be holding well; the dust nuisance was abated, and in time of wet weather the roadways were entirely free from mud. Regarding the permanency of the results obtained Mr. Rablin writes us that the work which was done last fall has proved very satisfactory, and the commission is now treating other roads. In a subsequent issue of *Engineering-Contracting* (Dec. 18, 1907), Mr. Rablin states that about half of the above yardage was treated again with Tarvia, due to the fact that it had begun to show signs of wear.

In 1907, about 90,000 additional sq. yds. of roadway were treated with Tarvia, the average cost being as follows:

	Per sq. yd.
Tarvia, 0.45 gal.....	\$0.0316
Stone screenings, 0.016 tons.....	0.0219
Labor	0.0196
Total	\$0.0731

**Engineering-Contracting*, June 12, 1907.

The organization and wages were as follows:

	Per day.
1 foreman	\$ 2.75
1 double team (2 horses and driver).....	5.00
1 single team (1 horse and driver).....	3.50
7 laborers cleaning road, at \$2.....	14.00
6 laborers spreading tar, at \$2.....	10.00
3 laborers spreading screenings, at \$2.....	6.00
Total	\$41.25
1 steam roller, assumed at.....	10.00
Total	\$51.25

I have assumed the \$10 daily rate for the steam roller (including coal, engineman, etc.), for Mr. Rablin does not state its rate.

Since the average cost of labor was 1.96 cts. per sq. yd., we infer that about 2,600 sq. yds. were treated per day, for $\$51.25 \div \$0.0196 = 2610$. If this inference is correct, we have the following itemized cost of the labor:

	Per sq. yd.
Foreman	\$0.0011
Teams, sweeping, sprinkling sand, etc.....	0.0033
Laborers cleaning road.....	0.0053
Laborers spreading tar.....	0.0038
Laborers spreading screenings.....	0.0023
Rolling	0.0038
Total	\$0.0196

It will be noted that the above contains no item for cost of heating the tar nor for hauling it.

Cost of Tarring Macadam, Jackson, Tenn.*—Mr. Logan Waller Page, Director, Office of Public Roads, gives the following data of work done under Mr. Samuel Lancaster's direction.

The macadam streets in the business center of Jackson were built originally of the hard silicious rock known as novaculite. About May, 1905, after fifteen years of wear repair of these streets became necessary.

The old surface was first swept clean with a horse sweeper. This was done because tar will not penetrate a road surface which is covered with dust and loose materials.

Next, the surface was loosened by means of spikes placed in the wheels of a 10-ton steam roller, the street reshaped, and new material added where needed.

The road was then sprinkled, rolled, bonded and finished to form a hard, compact, even surface, and allowed to dry thoroughly before either tar or oil was applied, for these substances cannot penetrate a moist road surface. The best results are obtained when the work is done in hot, dry weather, and accordingly the tar was first applied in August.

Other sections of streets and roads were built of new material entirely and according to well-known principles of macadam construction, but no tar or oil was put on them until after they had

**Engineering-Contracting*, July 4, 1906.

been subjected to traffic. Sections of country roads which had been built for periods of from one to two years were also treated with tar and oil.

The tar used was a by-product from the manufacture of coke and was practically free from moisture. It was received at the railway station in standard steel tanks of about 3,000 gals. capacity. A portable boiler was connected with the steam coils of these tank cars to heat the tar and keep it hot, thus saving time in bringing it to the temperature desired for spreading on the road. It was then taken from the tank cars and poured into a cylindrical tank wagon of 500 gals. capacity by means of a hand-lever pump. This portable tank had a small fire box under one end with a flue running directly beneath the tank to a smokestack at the other end. A fire was kept in the fire-box and the tar brought to a temperature which generally reached 210° F., but when placed on the road it was reduced to a temperature of from 160° to 190° F. The hottest tar produced the best results.

A horizontal pipe with an adjustable, longitudinal slot, attached to the rear of the wagon and extending down close to the surface of the road, was first used to spread the tar, but this became clogged and did not give an even flow. It was therefore abandoned, and in place of it a piece of four-ply 1½-in. rubber hose was attached to the wagon. This hose had a nozzle of 1-in. pipe, slightly flattened at the end to produce a broad stream, and was provided with a valve for controlling the flow. The tar was spread with this hose over a radius of about 15 ft. of road surface.

Laborers, with street cleaners' brooms of bamboo fiber, followed the tank and swept the surplus tar ahead. They spread it as evenly and quickly as possible, and in a layer only thick enough to cover the surface. One side of the street was finished at a time, and barricades placed to keep off the traffic until the tar had had time to soak into the surface. The time allowed for this process was varied from a few hours to several days. From the results obtained it can be stated that, under a hot sun, with the road surface thoroughly compact, clean, and dry, and with the tar heated almost to the boiling point and applied as described above, the road will absorb practically all of it in eight or ten hours.

A light coat of clean sand, screenings, or the clean particles swept from the surface of the road, may then be spread as evenly as possible and rolled in with a steam roller. These different top layers were applied to various sections, and in one case the road was left to dry without spreading anything except the hot tar. In another instance sand was applied to the tar within two hours, which resulted in the absorption of the tar by the sand and lessened its penetration of the road surface. It was necessary to remove this sand-tar mixture, which peeled up under traffic. A sufficient amount of tar, however, had penetrated the surface of the road to make it waterproof, and after more than seven months of service this section of street is in good condition.

In spreading the coat of material for drying the surface of the

road and absorbing the surplus tar, only enough should be used to cover it lightly, as, after rolling, this surplus material will be washed or blown away, or it may be removed with street sweepers and the surface left smooth and clean.

After more than seven months, including the winter season of 1905-6, the tarred streets and roads are still in excellent condition. They are hard, smooth and resemble asphalt, except that they show a more gritty surface. The tar forms a part of the surface proper and is in perfect bond with the macadam. Sections cut from the streets show that the tar has penetrated from 1 to 2 inches, and the fine black lines seen in the interstices between the individual stones show that the mechanical bond has been reinforced by the penetration of the tar. The tar is a matrix into which the stones of the surface are set, forming a conglomerate or concrete. A second coating applied a year after the first would require much less tar than the first, as the interstices of the rock would then be filled with tar.

On five different sections, having a total of 13,235 sq. yds., the average cost of the labor was about as follows:

	Per sq. yd.
Labor, sweeping, at \$1.25 per 10-hr. day.....	\$0.0014
Filling tank, heating tar, and hauling to the road	0.0012
Labor, applying tar.....	0.0030
Labor, applying sand or screenings.....	0.0030
Total labor	\$0.0086

The total labor was, therefore, less than 1 ct. per sq. yd. Negro labor was used, at \$1.25 for 10 hrs., and teams were paid \$3 per day. The average quantity of tar was 0.45 gal. per sq. yd. The labor cost of heating, hauling and applying the tar was 0.42 ct. per sq. yd., as above given, or practically 1 ct. per gal. of tar, exclusive of the labor of sweeping and of applying sand; but, including those two items of labor, the labor cost was practically 2 cts. per gal. of tar.

Cost of Oiling Macadam, Jackson, Tenn.*—Mr. Logan Waller Page gives the following. (For comparative data on tarring macadam at the same place and time, see page 300.)

Seven tank cars of oil, given by some Texas and Louisiana companies, were used at Jackson. It varied in quality from a light, crude oil to a heavy, viscous residue from the refineries. Over 7 miles of country road and several city streets were treated.

At first, some of the lighter crude oils were applied with the same tank wagon that was used for the tar. Hose and brooms were used to spread the oil, and practically the same process was followed as with the tar. The oil soaked into the macadam very quickly and left no coating on top. It caused the light covering of sand which was applied to pack down and gave the road a dark color.

**Engineering-Contracting*, July 4, 1906.

It was soon noticed that the preliminary sweeping was unnecessary, as the roads were practically free from dust, and oil and would penetrate the surface. The removal of detritus was a loss to the road, which had to be replaced by sand to prevent excessive wear on the stone. It was later found that it was much cheaper to use an ordinary street sprinkler than the tank wagon, and in this case spreading the oil with brooms was unnecessary.

The crude oil was used cold, and the cost of applying it with the different methods used is given below.

On a city street 8,266 sq. yds. were treated at the rate of 0.48 of a gal. of oil per sq. yd. with the use of the tank wagon and hose. The cost of labor per square yard was as follows:

	Per sq. yd.
Sweeping street	\$0.0011
Filling tank and hauling.....	0.0008
Oiling street	0.0024
Spreading sand	0.0014
Total	\$0.0057

On a country road 2,000 gals. were spread, covering 5,206 sq. yds., at a rate of 0.38 of a gal. per sq. yd. The average haul was 1 mile. Only the manure was removed before oiling. The cost of labor averaged \$0.0033 per sq. yd.

It took 9 men 30 mins. to spread 500 gals., or one tank load, and the 18-ft. road was covered at the rate of 1,860 ft. per hour. It took 28 mins. to fill the tank with oil.

With an ordinary street sprinkler, one man and team spread one load of 600 gals. of oil in 15 mins. The sprinkler thus spread 600 gals. in one-half the time that it took 9 men, with the tank wagon, to spread 500 gals.

The heavy residual oils were so thick when cold that they would not run through a 2-in. fire hose attached to the rear of the tank wagon, and it was necessary to pump the oil upon the road. The pump with which the tank was charged was used for this operation. Only one tank wagon (500 gals.) of the heavy oil was applied cold. It formed a thick, sticky mass on the top of the road that rolled about under pressure and seemed to have an unlimited capacity for absorbing the sand which was spread upon it. The street had to be cleared of the greater part of this mass of oil and sand within a short time.

After this experience the oil was heated in the tank car by steam, and better results followed. It still ran slowly through the hose and nozzle, and it was found cheaper to take off the hose and allow the oil to flow from the outlet of the tank wagon directly upon the road, where the men swept it over the surface with brooms. An air pump was tried, to increase the flow of the tank wagon by pressure, but the tank was not tight enough to prevent the escape of air, and this experiment was unsuccessful.

Twenty-four hours after the application of the residual oil it was covered with sand or limestone screenings, and in four days it was

firm enough to bear traffic without showing any wheel tracks. It shed the water well in a violent rain storm.

The following was the labor cost per square yard of putting residual oil on city streets with the use of the tank wagon. Approximately 0.71 gal. of oil was used per square yard:

	Per sq. yd.
Sweeping street	\$0.0016
Heating, loading and hauling.....	0.0017
Oiling street	0.0029
Spreading sand	0.0022
Total	\$0.0078

Excellent results can be secured by the use of this heavy residual oil if it can be applied to the surface of the road at a temperature approaching the boiling point.

The medium grade of oil, which was tried next, is classed by the refiners as "steamer oil." It was heavy enough to leave a slight coating on the surface, which made a very compact covering with the dust of the road. Only the heavy matter was removed from the surface of the road before applying the oil. It was heated by steam in the car, but was not hot when it reached the road. It was not safe to build a fire in the tank wagon, and the best road surface was obtained where the oil was at the highest temperature. Some method of heating the oil safely on the road would greatly improve the result. This could be accomplished with a steam traction engine having steam coils connected with the tank, the engine hauling and heating the tank while spreading the oil. Most of this oil was applied with the street sprinkler, and it sprayed readily when hot.

In applying the greater part of the oil on the country roads the following men and equipment were used:

	Per day.
1 foreman	\$ 2.00
6 laborers, at \$1.25.....	7.50
1 tank wagon	3.00
1 street sprinkler	3.00
2 firemen, at \$1.50.....	3.00
1 ton coal	4.00
Total	\$22.50

This force spread 3 tank wagons and 3 sprinkler tank loads, or 3,300 gals. per day, making the cost 0.7 ct. per gal. The 6 laborers (negroes) pumped the oil at the car and worked on the road. It will be noted that it required about 0.8 lb. coal to heat 1 gal. of oil.

No sweeping was done on the country roads except to remove manure and to spread the oil where it was inclined to puddle. No sand or other material was applied to the road after oiling.

More than seven months have now elapsed since the work was done. The light crude oil has produced little if any permanent results. The roads where it was applied are but slightly changed, and some dust arises on them from traffic. The only apparent result is a slightly darker color on the "shoulders" of the road, and

but little difference can be noticed between this and other sections of the road which were not treated. This oil was too volatile for the purpose, and where it has to be shipped for any distance does not justify the expense of using it.

The medium "steamer oil" from Texas has given good results. There is a thin surface coat of dust packed down that protects the stone from the grind and pounding of traffic. This effect is very noticeable in driving over it. The harsh grinding noise of the wheels, which is pronounced on the novaculite surface, disappears at once, and there is decided relief in driving upon it. It is practically noiseless. This coating is perhaps one-eighth of an inch thick, and is not a concrete, but compacted dust, which is made to cohere by the oil with which it is saturated. This road does not wash or "pick up," and the wear on the rock is much decreased.

Cost of Oiled Earth Street, Arkansas.*—Mr. Frank H. Wright gives the following:

The street in question (Helena, Ark.) was about 700 ft. long and was oiled for a width of 40 ft. The soil was a soluble yellow clay, and in heavy rainstorms there had always been much washing of the gutters and in the wagon tracks on the crown.

Preparatory to oiling, the street was thoroughly plowed twice for a width of 40 ft., the amount used for traffic, a small-pointed Avery plow with a steel beam being used. After plowing, a disc harrow was thoroughly applied, after which a toothed harrow was used until the street was like ashes. One team with a driver was used in this preliminary work, but a shaker was used with the plow. The plowing and harrowing consumed about two days.

The oil was brought to the street by a team carrying three 52-gal. barrels. To get the oil from the tank car a small lever pump was bolted to the floor timber of the car at the side of the tank, and a connection made to the inside of the tank by a siphon made of 2-in. wrought iron pipe and fittings. The driver with one man to pump was able to leave the street, go to the car and fill the three barrels and return exactly in 20 mins.

In applying the oil, a strip about 15 ft. wide was taken on each side of the street, the street not being closed to traffic, and three men, each equipped with a 2-gal. sprinkling can, with the spray removed, poured the oil on the pulverized surface. Each man worked in his own section, about 20 ft. long, the driver filling the sprinklers by pumping from the barrels with a tin oil pump.

A load of coarse sand was dropped about every 50 ft. on the oiled strip, and, during the absence of the wagon in refilling the barrels, this sand was spread by the men in the same manner that sand is applied over a newly grouted brick pavement.

After one side had been oiled and sanded, a strip on the other side was treated in a like manner, and the center strip was again plowed and harrowed, having become compacted by traffic. After the center strip had been treated the whole strip was gone over

**Engineering-Contracting*, Nov. 21, 1906.

with a toothed harrow, and was then oiled and sanded a second time, but was not harrowed again.

The work was done in the first week of July and until recently there had been comparatively little dust and no mud, nor had there been any more washing where formerly it was excessive after a hard rain. There have been several hard rains this summer, one coming soon after the street was treated.

In applying the oil it took the three men exactly one hour to dispose of the three 52-gal. barrels of oil over a surface of 15 ft. x 100 ft., or 1,500 sq. ft. One man scattered with a shovel one wagon-load of sand (about 24 cu. ft.) over an area of 50 ft. x 60 ft., or 3,000 sq. ft., in 15 mins.

The gang was as follows:

	Per day.
1 foreman, at \$1.50.....	\$ 1.50
2 teams, at \$3.00.....	6.00
3 laborers, at \$1.25.....	3.75
Total	\$11.25

It took this gang $3\frac{1}{2}$ days to oil 3,110 sq. yds., the cost being as follows:

	Per sq. yd.
Laborers, at \$1.25 per day.....	\$0.0054
Teams, at \$3.00 per day.....	0.0068
Foreman, at \$1.50 per day.....	0.0017
Total labor.....	\$0.0130
0.8 gals. oil, at 3 cts.....	0.0241
0.111 loads (24 cu. ft.) sand at 75 cts.....	0.0084
Grand total	\$0.0463

Since a team and driver and one man to pump the oil could pump and deliver 6 bbls., or 312 gals. per hr., this item of cost was 0.14 ct. per gal. Since it took 3 men 2 hrs. to spread the 6 bbls., or 312 gals., the cost of spreading the oil was 0.24 ct. per gal., making a total of 0.38 ct. per gal., even with this crude way of spreading the oil with 2-gal. sprinkling cans.

Cost of Oiling Macadam, New York State.*—Mr. Arnold G. Chapman gives the following description of oiling certain New York state roads in 1906.

An ordinary 400-gal. steel tank on wheels was equipped with an "oil distributor" or sprinkler of the kind that has been developed in California for distributing heavy oils. The characteristic features of this type of sprinkler are that the oil is distributed directly downward upon the road surface and that the width of the application may be regulated from 18 ins. to 6 ft., as can also the amount of oil applied, by the manipulation of levers by the operator, who sits in the rear of the tank. From his position the operator can adapt the flow of oil both as to quantity and width, as the condition of the road may demand.

To unload the oil from the 6,000-gal. U. T. L. cars, in which it

**Engineering-Contracting*, May 6, 1908.

was received, a diaphragm pump was used, fastened to the dome of the car. By means of an iron chute the oil was conveyed from the pump to the sprinkler tank. This method was rather cumbersome and unhandy and entailed the loss of too much time in setting up the pump and in unloading the oil, but it was the best and cheapest available at that time. However, it can be greatly improved upon when the oiling is undertaken on more than an experimental basis.

The oil used was that known as the Raglan oil, obtained through the Standard Oil Co., from their wells at Salt Lick, Ky., at a cost of 4.78 cts. per gal., f. o. b. at the various places where used. This is a crude oil, being black and heavy, due to the presence of asphalt, of which the producers claim a 30% to 35% base. When cold, the flow of oil is slow and sluggish, but when warm it flows with a reasonable degree of rapidity.

On the several sections of road treated the methods of application varied, some being sanded, others swept, and some treated, as left by the traffic. While the oil was being applied, traffic was not suspended, but the people chose the sides of the road not oiled, for a few days until the oil had been taken up by the surface and did not have a tendency to adhere to the vehicle tires and to be thrown upon the garments of the people riding or on vehicles. From observation during the experiments it was noted that the best results were obtained when the surface of the road was warm and dry and the day was also clear and warm.

About 18,700 gals. were applied to 8 different macadam and gravel roads, having an aggregate of $18\frac{1}{2}$ miles, having an aggregate width of 10 ft., making an average of about 1,400 gals. per mile, or nearly 0.24 gals. per sq. yd. The average haul was $1\frac{1}{2}$ miles.

Ordinarily the gang was one team (with driver) and one laborer to pump oil and to operate the levers of the oil distributor when sprinkling. The average labor cost per gallon was as follows, team receiving \$4 per 8-hr. day, and laborer, \$1.75:

	Per gal.
0.006 hr. team, at \$0.50.....	\$0.0030
0.007 hr. laborer, at \$0.25.....	0.0015
Total	\$0.0045

To this cost of approximately $\frac{1}{2}$ ct. per gal. should be added the cost of supervision, and of plant charges.

The average cost per sq. yd. was as follows (excluding supervision):

	Per sq. yd.
0.24 gal. oil, at 4.78 cts.....	\$0.0115
Labor, 0.24 gals. spread, at 0.45 ct.....	0.0011
Total	\$0.0126

At $1\frac{1}{2}$ cts. per sq. yd., a mile of road 10 ft. wide was oiled for \$75, not including supervision nor plant charges.

One stretch of gravel road 2.8 miles long and 8 ft. wide was oiled

with 3,490 gals. in 2 days at the following cost, although the oil was hauled an average of $2\frac{1}{2}$ miles:

	Per gal.
0.0048 hra. team, at \$0.50.....	\$0.0024
0.0048 hrs. pumpman, at \$0.22.....	0.0010
Total	\$0.0034

The cost per sq. yd. was:

	Per sq. yd.
0.26 gal. oil, at 4.78 cts.....	\$0.0124
Labor, 0.26 gal. spread, at 0.34 ct.....	0.0009
Total	\$0.0133

The item of supervision (including traveling expense) is given in none of the above summaries of cost, for it was exceedingly high (about 0.6 ct. per gal., or twice what the actual spreading cost), due to the fact that a state engineer accompanied the gang and traveled from road to road at an expense that would not ordinarily be called for except in cases of experimental work like this.

Cost of Oiling Macadam, Kansas City, Mo.*—Mr. W. H. Dunn gives the following relative to oiling 375,400 sq. yds. of park roads (macadam) in 1907. During the year most of the roads were given two treatments of residuum oil from the Kansas field. The price of the oil was 77 cts. per bbl. of 42 gals., or 1.84 cts. per gal.

The first treatment with oil, during May, June and July, cost as follows:

	Per sq. yd.
0.32 gal. oil, at 1.84 cts.....	\$0.0059
Labor and screenings.....	0.0089
Total	\$0.0148

This is a trifle less than $1\frac{1}{2}$ cts. per sq. yd.

The second oiling was done in August, September and November, covering 260,000 sq. yds. in addition to the 375,400 that had been oiled in the early summer, and the cost was as follows:

	Per sq. yd.
0.25 gal. oil, at 1.74 cts.....	\$0.0044
Supplies, repairs and screenings.....	0.0008
Labor	0.0030
Total	\$0.0082

The limestone screenings formed a considerable part of the cost of the first oiling, but a very small part of the cost of the second oiling. It will be noted that the two oilings cost about $2\frac{1}{2}$ cts. per sq. yd. for keeping down the dust during the year. No sprinkling with water was necessary after a road had once been oiled. During the previous year, the cost of sprinkling 585,000 sq. yds. (including asphalt and creosoted blocks) with water had been 2.4 cts. per sq. yd.

The methods of unloading the oil, preparing roadway, spreading, were as follows:

Two steel receiving tanks, of 8,000 gals. capacity, were erected at

*Engineering-Contracting, Jan. 22, 1908.

a total cost of \$741.99, connected with a 4-in. pipe-line from receiving tank to the side track, permitting of unloading tank cars by gravity, the receiving tanks being also established at such an elevation as to permit loading the sprinkling carts by gravity from the receiving tanks. Two portable boilers were purchased at \$67.50 each, for the purpose of heating the oil in tanks and in sprinkling carts. When the macadam was absolutely dry and hard, the entire surface of the roadway was swept clean of dirt and screenings. The sweepings were left along the edge of the gutter for protection to the cement work, then the oil was applied from the sprinkling-carts. To the regular sprinkling-carts was attached a tin trough, perforated with $\frac{1}{4}$ -in. holes, to obtain an even distribution of the oil. The entire surface of the roadway was then flooded with oil and thoroughly broomed in, after which the sweepings from the gutter, with sufficient limestone screenings to form a slight dressing, were cast over the oil and thoroughly rolled with a steam roller.

The organization of the gang used in applying the oil was simply teams for ordinary city sprinkling wagons, usually from three to four teams, depending on the length of haul from the distributing plant, and from eight to ten ordinary laborers about equally divided between sweeping the screenings to the gutters ahead of the oiling and spreading the oil with brooms and casting the sweepings back over the oil after it was spread.

Cost of Tar Macadam, Massachusetts.*—Mr. Arthur H. Blanchard gives data upon which the following is based, relative to experimental work done by the Massachusetts Highway Commission in 1904.

Three methods of construction were used, which may be termed (1) the mixing method, (2) the grouting or penetration method, and (3) the Gladwell system.

By the Mixing Method.—With the exception of the addition of tar, the method of construction used was similar to that employed in the building of an ordinary macadam road.

After the subgrade had been thoroughly rolled, the No. 1 broken stone (varying in size from $1\frac{1}{4}$ to $2\frac{1}{4}$ in. in their longest dimensions) was spread to a depth of 6 in. and rolled to 4 in.

[Note.—While the statement is made that a 6-in. layer was rolled to 4 in., no such compression as this is possible.]

Tar, which had been heated in an ordinary tar kettle to the boiling point, was then sprinkled on the rolled surface by means of dippers.

The No. 3 stone (varying in size from $\frac{1}{2}$ to $1\frac{1}{4}$ in. in their longest dimensions) was next deposited on dumping boards and thoroughly mixed with hot tar with the aid of rakes and shovels. This mixture was applied on the No. 1 course to a depth of 3 in. and rolled to 2 in.

A thin coat of dust, which would pass through $\frac{1}{8}$ -in. mesh was then spread on the surface and then rolled into the No. 3 course

**Engineering-Contracting*, Oct. 7, 1904.

to fill up the voids and to provide a smooth surface. The work was carried on only when the broken stone was dry.

The stone was granite and hornblende schist. The work was done in May.

Tar from the Providence Gas Works, and having a specific gravity of 1.25, was used, and its cost delivered on the road was:

	Per bbl.
52 gals. tar	\$2.75
Freight, 2½ miles	0.52
Haul, averaging 2,000 ft.	0.13
Barrel	0.75
Total	\$4.25
Deducting rebate of \$0.75 per bbl. and adding return freight of \$0.19, net deduction.....	0.55

52 gals., at 7.4 cts. \$3.70

About the same number of square yards of 8-in. tar-macadam road was built per 10 hr. day as is built of ordinary macadam, namely, 233 sq. yds., using a 10-ton steam roller and the ordinary macadam gang with the following extra men:

	Per day.
2 tar men, at \$1.75	\$3.50
3 laborers mixing and placing, at \$1.50	4.50
Total extra labor, 233 sq. yds., at 3.5 cts.	\$8.00

Therefore, the added cost of this 8-in. tar macadam over ordinary 6-in. macadam was as follows:

	Per sq. yd.
Extra labor (as above given)	\$0.035
Fuel for melting tar and interest and depreciation of tools	0.005
1½ gals. tar, at 7.4 cts., delivered	0.093
Total	\$0.133
Deduct saving of water cart for sprinkling (\$4 per day)	0.013
Net increased cost due to use of tar	\$0.120

On another stretch of road built the previous year, 1.15 gals. of tar were used per sq. yd., but the cost per gallon was greater due to the fact that the barrels were not returned. The tar in that case was hauled 6½ miles at a cost of 50 cts. per bbl. of tar for hauling.

The difference in cost of the tar-macadam without the tar on the No. 1 course and with that tar (about 1/5 gal. per square yard) spread on the No. 1 course, was not appreciable. It is believed that the painting of the No. 1 course with tar is not necessary. In common with all methods of construction, with the single exception of the Gladwell system, it is necessary, in order to secure a maximum penetration of the broken stone by the tar, and adequate incorporation of the tar in the macadam, to allow the No. 2 course to remain without rolling and sanding for from 1 to 3 days, depending on the climatic conditions. It was found to be inadvisable to roll the tarred surface during the warm part of the day, as there was a tendency for the No. 2 course to shift if the tar was soft.

Tarvia-macadam constructed by the mixing method appeared to be a fac-simile of the tar-macadam made with tar distilled for 3 hours on the road. It is believed that it is primarily a question of economics whether it is preferable to take gas-house coal-tar direct from the work and distill it on the road, or purchase distilled coal-tar, in the form of Tarvia, for example. It should be borne in mind, also, that tar distilled at permanent works will give a more uniform product.

By the Grouting Method.—The macadam was constructed by spreading 3 ins. of clean, dry No. 1 rock on the rolled subgrade and rolling the same to 4 ins. On the No. 1 course was then spread 2½ to 3 ins. of clean, dry No. 2 rock, which was lightly rolled. The tar, which had been heated in the regular tar kettles, was next poured on the surface of the No. 2 course and allowed to penetrate. The depth of penetration varied from 1 to 2½ ins., depending on the size of the stone comprising the upper course and the amount of rolling the surface had received. Trap rock chip screenings were then spread to a depth of ½ to ¾ in. and thoroughly rolled.

In the construction of the tar-macadam by the grouting or penetration method, the tar was spread over the surface by dippers. This method was very unsatisfactory, an unequal application being the result. In order to procure an efficient road, more tar was applied in patching, the original application of 1.25 gallons being thus increased to 1.87 gallons. If this method is to be used, pouring pots with fan-shaped spouts, or a fan-nozzle connected with a hose from a tank-wagon, should be used, or preferably a spreading machine similar to the Laissally or Aitken. Even with a machine of the most approved type, and with the stone heated either before or after deposition, it is doubtful if the tar-macadam surface thus constructed would be as uniformly bound together as when laid by the mixing method. The average rate of progress tarring this section was 389 sq. yds. per day, with two tar men and one common laborer. The cost was as follows:

	Per sq. yd.
1.87 gals. tar delivered, at 7.4 cts.....	\$0.138
Labor (2 tar men and 1 laborer).....	0.013
Fuel and plant interest, etc.....	0.005
Total	\$0.156
Deduct saving water sprinkling.....	0.013
Total extra cost	\$0.143

This 14.3 cts. per sq. yd. is to be added to the cost of ordinary 4-in. macadam.

The grouting method is particularly applicable to the resurfacing of old macadam, which can first be loosened to a depth of 3 or 4 ins., with a scarifier (at a cost of 0.7 ct. per sq. yd.) and then grouted with about 1½ gals. per sq. yd. and rolled.

By the Gladwell System.—In the construction of tar-macadam by the Gladwell system, the bituminous mastic, consisting of tar and stone chips varying in size from ½ to ½ in. in their longest

dimensions, was mixed in a regular mortar box. This mixture was spread to a depth of $\frac{3}{4}$ in. on the No. 1 course of stone, and the No. 2 course of broken stone was then laid upon it. A coating of tar was spread on the surface, and, after screenings had been applied, the section was thoroughly rolled with a steam roller. The upward penetration of the tar was not measurable, and the surface coat did not penetrate more than $1\frac{1}{2}$ in. In order to procure satisfactory results, it will be necessary to have the No. 1 course so thoroughly compacted as to hold a semi-fluid mixture; the stone composing the No. 2 course should be larger than that generally used, and should be well heated, and, finally, it will be necessary to use a light asphalt roller in order to draw the fluid mixture gradually to the surface, and not attempt to crush the No. 2 course into the binder. Under no circumstances is it believed that the method will prove as efficacious or economical as either the mixing or penetration methods of construction. The rate of progress of this class of work was slow, and would average 156 sq. yds. per day. The labor item was high, two tar men and four common laborers being required, making the labor cost \$0.06 per square yard. The tar, 1 gallon per square yard in the mastic and 1.25 gallons on the surface, cost \$0.167 per square yard. Summarizing we have the following cost:

	Per sq. yd.
2.25 gals. tar, at 7.4 cts.....	\$0.167
Labor (2 tar men and 4 laborers).....	0.061
Fuel and plant interest, etc.....	0.005
Total	<u>\$0.233</u>
Deduct saving water sprinkling.....	0.013
Total extra cost.....	<u>\$0.220</u>

This 23 cts. per sq. yd. must be added to the cost of ordinary 6-in. macadam.

Cost of Tar Macadam, Duluth, Minn.—Mr. E. K. Coe gives the following: Duluth began laying tar macadam in 1902, and it increased so rapidly in popularity that 90% of the total pavement laid in 1906 was tar macadam (71,500 sq. yds.). The pavement is 8 ins. thick, consisting of a tar grouted macadam base 6 ins. thick, covered with 2 ins. of tar macadam that has been mixed in a machine. This 6-in. base is composed of crushed rock $\frac{1}{4}$ to $2\frac{1}{2}$ -in. in size, and is rolled with a steam roller. Then hot tar is spread over the base, 1 gal. per sq. yd., by means of large sprinkling cans, the spout of the can being flared and measuring $\frac{1}{2} \times 8$ ins. This tar is drawn from a tank wagon, and is spread immediately in advance of the spreading of the 2-in. wearing coat of tar macadam (or tar concrete). This wearing coat is mixed in a portable mixing plant owned by the city. The plant has a capacity of 1,000 sq. yds. of 2-in. wearing coat per day; its shipping weight is 18 tons and it is easily hauled to any part of the city by a steam roller. The plant was built by the Toledo Construction & Supply Co. of Detroit, and cost the city \$10,300. It is rented to

the contractors at \$20 a day, straight time, the city furnishing the engineman. As many as 1,300 sq. yds. of 2-in. wearing coat have been mixed by this plant in a day.

The stone for the wearing coat is first heated in this plant to 175° to 200° F., which is the same temperature that the tar receives.

The stone is graded in size to reduce the voids to about 7%. When the voids are filled, however, and the stone coated with tar, the particles of stone are separated, so that 11% by bulk of tar is necessary. The following is one of the successful batches:

344 lbs.	stone passing 1½-in. screen and caught on 1-in.
152 lbs.	stone passing 1-in. screen and caught on ¾-in.
175 lbs.	stone passing ¾-in. screen and caught on ½-in.
275 lbs.	stone passing ½-in. screen and includ. fine dust.
54 lbs.	tar.

1,020 lbs. total.

Usually 6 or 7 batches of 800 lbs. make a wagonload, bottom dump wagons being used.

Plant foremen are tempted to use an excess of tar, to make a batch appear mixed before it really is, and thus make a bigger day's run.

Tar from the Duluth tar plant is used; it is a by-product of the coke ovens and is very uniform.

The liquid tar for the base is hauled in steel tank wagons, which are provided with small furnaces to keep the tar melted.

The mixed material for the 2-in. wearing coat is dumped from the dump wagons onto a sectional platform, shoveled to place, raked out smooth, and immediately rolled with a 15-ton roller. This course is 2 ins. thick after rolling. When rolled smooth and compact, a flush coat of tar (5 lbs. per sq. yd.) is spread, to seal all surface voids. Formerly a "squeegee" (like a rubber window cleaner) was used for this flush coat spreading, but it was found preferable to use a special cart mounted on two small wheels and with a box 18 ins. square x 12 ins. deep. Behind the cart is a piece of heavy rubber belting set on edge, 8 ins. wide and 3 ft. long, bent to an arc of 60°. Some 7 gals. of fluid tar are poured into the box, in the bottom of which is a 1-in. hole, with a tapering iron plug which is operated by a lever from the drawbar, so that the man who draws the cart can manipulate the plug and deliver a small amount of tar directly in front of the rubber belt, or "squeegee."

Finally the surface is covered with a thin layer of hot rock, beech nut size, and rolled.

The following are the materials required per sq. yd. of 2-in. wearing coat and 6-in. base: 0.3 cu. yd. crushed rock and screenings and 3 to 3½ gals. tar, including waste.

The average contract price in 1906 was \$1.23 per sq. yd., which includes everything but grading, and includes a 5-yr. guarantee.

The gang required to mix and lay the 2-in. wearing coat is as follows:

Plant Force:

- 1 foreman.
- 1 engineman.
- 1 fireman.
- 1 mixer man.
- 1 weigh man.
- 1 feeder.
- 3 to 6 shovelers (according to location of pile of stone).
- 2 teams hauling tar.
- 1 watchman.

Street Force:

- 1 foreman.
- 3 men spreading tar binder on base.
- 3 shovelers.
- 3 rakers.
- 1 engineman on steam roller.
- 1 tar heater.
- 1 man on squeegee cart.
- 2 men spreading surface screenings.
- 1 watchman.
- 1 water boy.
- 3 to 5 teams according to length of haul.

Cost of Asphalt Macadam, Redlands, Calif.—Mr. C. C. Brown gives the following: During 1906, the city of Redlands, Calif., built 6 miles (100,000 sq. yds.) of asphalt macadam at a cost of 56 cts. per sq. yd., by contract. The city owns a crushing plant, and sells the rock to the contractor at \$1 per ton, f. o. b. cars. It is hauled 5 miles by rail. It requires $1\frac{1}{4}$ cu. yds. of crushed rock (measured in the cars after the 5-mile haul) to make 1 cu. yd. of the finished pavement, including the sand and the asphalt.

The crushed granite is spread in two layers, the bottom layer composed of stones $1\frac{1}{2}$ to 3 ins. in size, the top layer, $\frac{3}{4}$ to $1\frac{1}{2}$ ins. It is then filled with granite screenings. Each course is rolled, water being freely used while the screenings are being rolled in. As soon as the water dries out, heavy asphaltic oil (75% asphalt) at a temperature of 150° F., is sprinkled over the macadam, about 2 gals. per sq. yd., or even more. Excavations of the macadam show that the oil has penetrated $\frac{1}{2}$ to $\frac{3}{4}$ the way down. The street is then thrown open, and several weeks of traffic iron it out into a smooth pavement. If any ruts appear broken stone ($\frac{1}{2}$ to 1 in.) is placed on the macadam and covered with the asphaltic oil.

The asphaltic oil, or liquid asphalt, is applied from a tank wagon hauled by 4 horses. The tank is equipped with a "Glover oller" (now known as a petrolithic oller, made by the Petrolithic Pavement Co. of Los Angeles, Calif.). The "oller," or "distributor," is a cylinder having a series of openings, the flow being nicely controlled by a set of levers manipulated by a man on the wagon, who regulates the flow according to the speed of the team."

Four tanks, of 500 gals. each, or 2,200 gals., are distributed per day of 8 hrs., when the haul is two miles each way. The heating is done at the unloading tank by steam, which is also used to facilitate unloading the tank car.

The oil costs \$1 per 40-gal. barrel, including the freight, which is 33 cts. per bbl.

Cost of Petrolithic Macadam.—Mr. J. C. Black, in an article in the *California Journal of Technology*, Oct. 5, 1903 (reprinted in *Engineering-Contracting*, Nov. 11, 1903), gave the following: I have inserted an illustration of the rolling tamper and the gang plow, and have assumed wages and prices.

Petrolithic pavement originated in southern California some eight years ago, and since that time has given such great satisfaction that it is now to be found in many parts of the United States, and is even securing a foothold in foreign countries.

Petrolithic pavement consists of a compacted mass of earth, crushed rock or gravel and asphaltic oil, although, since the lighter oils in which asphaltum is dissolved do not remain permanently in the pavement, but disappear (mainly by evaporation) within a few months after its completion, we may properly call it a mixture of earth, rock and asphalt. The rock is intended to act as a wearing coat, and hence is kept mainly near the surface. However, it is not the composition, but the manner in which it is treated, that constitutes the most important and characteristic feature of a petrolithic pavement, for this is the only method in which the entire material of the street is tamped into a compact mass of uniform density.

After the road has been brought approximately to grade and is properly crowned, the surface is broken to a depth of 6 to 8 ins., by plowing or otherwise, and then pulverized by farm cultivators and harrows or other machinery. The application of water, often in quantities amounting to several gallons to the square yard of surface covered, usually greatly expedites the pulverization.

After the ground is reduced to a sufficiently fine condition, oil is applied at the rate of three-fourths of one gallon to each square yard of surface and is cultivated in. Another application of oil equal to the first is then made and cultivated, after which the ground is plowed 6 ins. deep, a gang plow, Fig. 6, generally being most satisfactory for this work. The plowing should be such as will thoroughly turn the furrow, and it will generally bring to the surface a small amount of soil which has been untouched by the oil. A slight amount of cultivating or harrowing serves to work out the ridges left by the plow, and the third application of oil, amounting to one gallon to the yard, is then made and cultivated in.

After this it is advisable to put on the road grader, and it is the writer's experience that a liberal use of it is effort well spent. It will be observed that up to the present stage all the work on the road has been done along longitudinal lines—applying the oil and plowing must of necessity be so carried on, and while cultivating

and harrowing may be done zig-zag fashion, it is generally more satisfactory to work in a straight line. While this work results in a fairly uniform mixture of soil and oil, there is a certain tendency toward the formation of streaks, and it is in the correction of this that the great benefit of the road grader as a mixing device

Fig. 6. Petrolithic Gang Plow.

becomes apparent. The soil is in a very loose and finely divided condition, so that with the grader blade set at an angle, a deep cut may be made, and by thus shifting the material from side to side a number of times, the streaks may be entirely removed.

The road is now brought back to grade, and a petrolithic rolling tamper, Fig. 7, is set to work. This tamper consists of a roller

Fig. 7. Petrolithic Rolling Tamper.

about 3 ft. in diameter, the surface of which is studded with iron teeth or feet 9 ins. long and terminating in a slightly rounded surface of about 4 sq. ins. area. The total weight of the machine is between 4,800 lbs. and 5,000 lbs., and as there are 10 or 11 ft. in a row, the weight on each is approximately 450 lbs., or over 100 lbs. to the square inch of surface. The device is patented, and is for sale by the Petrolithic Pavement Co. of Los Angeles. It is drawn

by four horses, from four to six being required, according to conditions. As it passes over the loose material of the street, the feet sink to a depth of 6 or 8 ins., and being flat ended each one leaves a small, compact mass of earth and oil at the place it struck. In order to secure uniform results and prevent the too rapid tamping, a cultivator must be used in connection with the tamper. The cultivator should be adjusted at first to work to approximately the same depth as the tamper, but after two or three trips over the ground, should be raised a notch. After this it should be raised from time to time, but never more than a single notch at a setting, and care should always be taken to avoid too great haste and consequent imperfect tamping. It will be observed that this process builds the pavement "from the bottom up," so to speak, thereby producing a dense mass for the full thickness.

When the road has been tamped so that 2 or 3 ins. of loose material remain on the surface, the tamper should be taken off and the surface smoothed with a road grader or drag. After this, a 2 or 3-in. layer of 1½-in. gravel or crushed rock should be spread upon the road and cultivated so as to mix it with the earth. The rock may be spread by hand, in which case dumping should begin at the end of the road where the wagons arrive, so that they may travel over it instead of over the loose earth, or it may be dumped in a single line down the center of the road, and then spread with the grader. In point of cost, one method offers little advantage over the others. The hand spreading usually gives more uniform results.

After the rock is spread and cultivated, the last coat of oil, amounting to one gallon to the square yard, is applied, and the ground again cultivated. It should then be plowed as deeply as possible without disturbing the tamping already done. A few trips of the cultivator will smooth out the surface, and the tamper may again be set to work. When only a small amount of loose material (say an inch) remains, the cultivator may be taken off altogether, and the surface given a light treatment with a grader or drag before the tamper finishes its work.

A smooth roller will improve the appearance of the newly completed road, but will add little to its efficiency or durability.

The use of water from time to time during the work is a necessity, but because of varying conditions of weather and variety of soils, fixed rules for its use are impossible. In general it will be found that sandy soils must be kept wet from start to finish of work, while clay or adobe requires comparatively little water, and that mainly during the tamping process. If too much water is used on soil of this nature, the almost inevitable result will be clogging of machinery and consequent delays. For applying water, the oil wagons will be found entirely satisfactory.

It is needless to remark that the details of building a petrolithic pavement may be varied considerably, and that good results can be obtained in several ways. In fact, as in many other lines, there are no two pieces of work which can be conducted in exactly the same

manner. Some of those who have been most successful with this form of construction prefer to put the rock on the road before any tamping has been done. This is cultivated, and after the final coat of oil has been applied is plowed under. It might be thought that this would result in the rock being distributed through so great a thickness of soil that its value as a wearing surface would be lost, but the fact is that even when plowed under as much as 6 ins. the cultivation rapidly brings it to the top. If it is attempted to mix it with too small a quantity of soil, a large amount of rock will remain loose on the surface, and must be removed entirely from the street.

Most of the older petrolithic roads of southern California were built without the use of any rock or gravel, and the satisfaction they have given proves that where the price of rock is high and the keeping down of expenses imperative an excellent pavement may be built of nothing but the natural material of the street mixed with oil.

As to the character of soil in which petrolithic pavement may successfully be built, almost anything will do, provided it is free from a large amount of alkali or other ingredient which will cause decomposition of the oil. In sand the adhesive qualities of the oil will hold the particles together and make possible a good road, where otherwise some expensive paving material would be necessary. No soil gives better results than adobe (clay), although it is hard to work, and consequently may slightly increase the cost. Between the extremes of sand and adobe equal satisfaction will be found.

The greater the amount of asphalt in the oil, the better, and the specifications of the city of Los Angeles require a minimum of 70 per cent. Natural oils having this amount of asphalt are difficult to obtain, but the Sunset District produces some which run from 75 to 80 per cent or even more. These are used exclusively for road oils, and can generally be had at a reasonable price, say 50 cts. per bbl. of 42 gals. Refinery products or residuums are frequently used, and these prove satisfactory when the quality of the asphalt contained in them is unimpaired. The objection to their use arises from the fact that an overheated or burned asphalt lacks the adhesive qualities necessary in a good road oil. A special and expensive test is necessary to determine whether overheating has taken place, and as it should be applied to every carload, besides causing delay, it will form quite an item of expense. Care should be taken to get an oil comparatively free from water and sediment, many specifications requiring the rejection of all oil containing more than 2 per cent of such foreign matter.

It is commonly required that the oil be applied to the road at a temperature of not less than 150° F., and some oils, because of their viscosity, cannot be easily handled at a lower temperature. Although there are still some advocates of the use of cold oil, the general opinion is "the hotter the better."

For heating the oil a portable boiler of some sort is generally

used. The oil may be heated in the cars in which it is delivered, which are usually equipped with steam pipes for this purpose, or it may be run into a tank or pit in which a steam coil has been set. In soil of a clayey nature, a pit without lining may be used, as the oil will penetrate the ground only a few inches. An oil pump with the necessary valves and connections for unloading from car and loading into wagons, will complete the heating establishment.

Oil tank wagons are built of various capacities, the common sizes holding from 800 to 1,000 gals. The distributors, of which there are several good designs, are attached to the rear of the tank, and spread the oil for a width of 6 or 7 ft. Some are divided into three or four sections, so that a narrower strip may be covered if desired. The oil holds its heat well, and if conditions demand, the heating plant may be situated several miles from the work and still allow of the delivery of oil at the required temperature.

Warm weather is desirable for carrying on the work, as when it is cold the oil tends to drag or form into chunks, with resulting irregularities and soft spots in the finished roadway. The road may be opened for traffic as soon as the tamping is finished.

A complete outfit for building petroleolithic pavement will be about as follows, though, of course, the magnitude of the work will determine the number of pieces of machinery necessary. It is often possible to rent a portion of the plant, and some cities have their own outfits, which they are prepared to rent to contractors, generally at so much a block:

- 1 portable steam boiler, with fittings.
 - 1 oil pump and connections.
 - 1 pit or tank of not less than 10,000 gals. capacity, and fitted with steam heating coils.
 - 1 oil wagon and distributor.
 - 1 road grader.
 - 1 road drag (home made).
 - 3 dump wagons, for rock.
 - 1 rooter plow.
 - 1 gang plow.
 - 3 cultivators.
 - 2 rolling tamper.
- The operating gang is as follows:
- 1 foreman.
 - 1 grader man and oil wagon operator.
 - 1 fireman.
 - 7 teamsters.
 - 3 laborers.
 - 35 horses or mules.

The accompanying figures give an average of the amount of labor and material per sq. yd. on several streets, all of which were in clay or adobe soil. In sandy soil more tamping and more water are required, but the preliminary work is much easier. The amount of work necessary varies widely, and depends entirely on local conditions, but by substituting rates of wages and costs of materials

in this table an approximation to the cost of doing the work may be obtained. Proper allowance must, of course, be made for interest and depreciation or for rental of plant.

	Per sq. yd.
<i>Plowing and Pulverizing:</i>	
0.004 hr. rooter plow, 6 horses and driver, at \$0.80.....	\$0.0032
0.004 hr. cultivator, 4 horses and driver, at \$0.60.....	0.0016
0.002 hr. tamper, 6 horses and driver, at \$0.80.....	0.0016
<i>Oiling:</i>	
0.0018 hr. fireman, heating oil, at \$0.20.....	0.0036
0.007 hr. oil wagon, 6 horses and driver, at \$0.80.....	0.0056
0.004 hr. oil wagon operator, at \$0.20.....	0.0008
0.0015 hr. hand labor, at \$0.20.....	0.0003
<i>Mixing Oil and Soil:</i>	
0.0015 hr. rooter plow, 6 horses and driver, \$0.80.....	0.0012
0.0027 hr. gang plow, 4 horses and driver, at \$0.60.....	0.0016
0.022 hr. cultivator, 4 horses and driver, at \$0.60.....	0.0132
0.007 hr. hand labor, at \$0.20.....	0.0014
<i>Watering:</i>	
0.005 hr. water wagon, 6 horses and driver, at \$0.80.....	\$0.0040
<i>Handling and Hauling Crushed Rock:</i>	
0.042 hr. labor, loading into wagons, at \$0.20.....	0.0084
0.056 hr. wagon hauling, 2 horses and driver, at \$0.40.....	0.0224
0.009 hr. labor, spreading rock, at \$0.20.....	0.0018
<i>Grading:</i>	
0.005 hr. road machine, 6 horses and driver, at \$0.80.....	0.0040
0.005 hr. man operating machine, at \$0.20.....	0.0010
0.001 hr. road drag, 4 horses and driver, at \$0.60.....	0.0006
<i>Tamping:</i>	
0.028 hr. rolling tamper, 6 horses and driver, at \$0.80.....	0.0184
0.011 hr. cultivator, 4 horses and driver, at \$0.60.....	0.0066
<i>Smooth Rolling:</i>	
0.003 hr. roller, 6 horses and driver, at \$0.80.....	0.0024
<i>Miscellaneous:</i>	
0.009 hr. labor removing large stones, etc., at \$0.20.....	0.0018
0.0015 hr. wagon, 2 horses and driver, at \$0.40.....	0.0006
<i>Superintendence:</i>	
0.019 hr. foreman, at \$0.40.....	0.0076
Total labor	\$0.1137
<i>Materials:</i>	
3.50 gals. asphaltic oil, at \$0.02.....	\$0.0700
0.09 gals. oil for fuel (heating), at \$0.02.....	0.0018
5.50 gals. water for sprinkling, at \$0.0002.....	0.0011
0.083 cu. yds. crushed rock, at \$1.00.....	0.0833
Grand total, labor and materials.....	\$0.1949

It will be noted that the three items of loosening the soil and re-compacting it with the rolling tamper total as follows:

	Per sq. yd.
Pulverizing the soil.....	\$0.0064
Grading	0.0056
Tamping (excluding cultivating).....	0.0184
Total	\$0.0304

This cost of 3 cts per sq. yd. shows what it would cost to break up, shape with a road machine and tamp the subgrade of a road or street with a rolling tamper, preparatory to laying any sort of pavement. Practically the same price is charged by Massachusetts contractors for "shaping" the subgrade of macadam roads, using

only the old-fashioned and inferior methods. Each rolling tamper compacted 400 sq. yds. per day of 9 hrs.

It will be noticed that the labor item of oiling totals a trifle more than 1 ct. per sq. yd. (0.3 ct. per gal. of oil), excluding the cost of the fuel oil used in heating the other oil, the cost of which is given (under Materials) at 0.18 ct. per sq. yd., making a total of 1.18 cts. per sq. yd. Since $2\frac{1}{2}$ gals. of oil were used per sq. yd., this is equivalent to $\frac{3}{4}$ ct. per gal. for heating, pumping, hauling and sprinkling the oil on the road.

It will be noted that the crushed rock was spread on to a thickness of 3 ins., measured loose, and that when expressed as a cost per cu. yd. of loose rock instead of per sq. yd., we have the following:

	Per cu. yd.
Loading wagons	\$0.108
Hauling	0.269
Spreading	0.022
Total	\$0.399

It will be noted that the superintendence cost 17 per cent of the total labor.

It will be noticed that the price assumed for the asphaltic oil (2 cts. per gal.) is low—about one-quarter what it costs in most places outside of California.

None of the foregoing costs include an allowance for interest, depreciation and repairs of plant, nor cost of installing and removing plant.

Cost of Petrolithic Road.—The method of construction was similar to the work just described, except that the broken stone was omitted, and the road was built of the natural soil mixed with asphaltic oil. It was tamped with a petrolithic rolling tamper.

The wages actually paid were as follows per day of 9 hrs.:

Laborer or driver.....	\$2.50
Horse, without driver....	1.00
Foreman	3.00

The cost was as follows, excluding installation of plant and interest, depreciation and repairs:

	Cts. per sq. yd.
Preliminary team work.....	0.26
Plowing with rooter plow.....	0.32
Pulverizing soil	0.34
Sprinkling water	0.27
Leveling with road machine.....	0.14
Cultivating	0.27
Mixing oil and soil with cultivator.....	1.06
Sprinkling water	0.20
Tamping with rolling tamper.....	1.50
Final leveling	0.20
Foreman	0.64
Total labor	5.20
Oil, 2 gals. at $2\frac{1}{2}$ cts. delivered on the road.....	7.50
Grand total	12.70

It will be noted that the labor items do not include heating and

hauling the oil to the road, for this cost is included in the price of $2\frac{1}{2}$ cts. per gal. paid for the oil. Outside of California it is at present impossible to get asphaltic oil at any such low price.

The soil was a hard clay which required 5 gals. of water per sq. yd. (or about 30 gals. per cu. yd.) to soften the clods so that they could be broken up.

Four horses and a driver operated each rolling tamper, and each tamper compacted 435 sq. yds. per day.

The roter plow was operated by 6 horses, 2 drivers and 1 man holding the plow. They broke 4,200 sq. yds. per day, and, estimating a depth of 6 ins., the plow loosened 700 cu. yds. daily.

The water was hauled by 6 horses in a wagon holding 840 gals., the wheels of the wagon having tires 6 ins. wide.

A portable oil heater and oil pump loaded the oil from tank cars into 1,000-gal. tank wagons, requiring 20 mins. to load a wagon.

Cost of Telford Roads, New Jersey.—A telford road consists of a "bottoming," 6 to 12 ins. thick, made of rough stone blocks supporting a macadam surface 3 to 6 ins. thick. If the stone for the "bottoming" is limestone or sandstone that comes out in thin layers, readily shaped with a hammer into rectangular blocks, the "bottoming" is laid like a rough stone block pavement. But if the stone is a granite or trap that breaks out in irregular chunks, or if cobblestones are used, no attempt is made to lay a rough block pavement; and the "bottoming" then becomes a sort of macadam itself, consisting of large and small pieces. This last type of telford is the kind so largely used in the towns of northern New Jersey where trap rock is available.

The typical New Jersey telford is made of a "bottoming" 6 ins. thick, consisting of chunks of trap rock broken with hammers after delivery on the road until no chunk is more than 6 ins. thick. The spalls are packed in between the larger stone, and earth is shoveled over the stone from the side of the road until few stones are visible. Then a 5,500-lb. horse-roller is run over the stone before the 3-in. macadam is placed upon it. The macadam is bound with earth, and finally a thin layer of screenings is placed over all—more for appearance sake than for usefulness. The cost of quarrying the trap rock for the "bottoming" and the cost of crushing the portion of it that is used for the macadam surface, will be found in the section on Rock Excavation.

In building a telford pavement on a New Jersey village street, the pavement was made 16 ft. wide. The stones for the bottoming were dumped from wagons, and a gang of 6 men broke the larger ones and placed them all by hand carefully so as to secure a compact "bottoming" 6 ins. thick. This gang of 6 men averaged 4 cu. yds. of bottoming laid per man per 10-hr. day, at a cost of 40 cts. per cu. yd. for placing the "bottoming" after delivery. It took 1.2 cu. yds. of loose stones measured in the wagon to make 1 cu. yd. of "bottoming."

The macadam surface would have cost as much as any other macadam of equal thickness (3 ins.) had it not been for the use of earth as a binder instead of screenings. It took 1.2 cu. yds. of broken stone to make 1 cu. yd. of rolled stone, for a horse roller was used, and it did not compact the stone as much as a steam roller would. The cost of this broken stone can be estimated by data already given. The cost of rolling the "bottoming" and the macadam surface were not kept separately; but rolling both was as follows:

The $2\frac{1}{2}$ -ton roller, drawn by a team, averaged 150 lin. ft. of roadway 16 ft. wide per day of 10 hrs., which is equivalent to 80 sq. yds. per day, at a cost of 4 cts. per sq. yd. By far the greater part of the rolling was confined to the 3-in. macadam. The team on the roller was taken off from time to time and hitched to a sprinkling cart. Water for sprinkling the macadam was obtained from a nearby hydrant. Summarizing the costs, we have the following:

	Per cu. yd. in place.
Cost of bottoming (6 ins. thick).	
Quarrying and loading 1.2 cu. yds. at 40 cts.....	\$0.48
Hauling 2 miles, 1.2 cu. yds. at 40 cts.....	0.48
Placing	0.40
Total per cu. yd. in place.....	\$1.36
Cost of macadam surface (3 ins. thick).	
Quarrying and crushing 1.2 cu. yds. at 55 cts.....	\$0.66
Hauling 2 miles, 1.2 cu. yds. at 40 cts.....	0.48
Spreading 1.2 cu. yds. at 12 cts.....	0.14
Shoveling on earth for binder, 0.4 cu. yds. at 12 cts..	0.05
Sprinkling and rolling, 4 cts. per sq. yd.....	0.48
Total per cu. yd. in place	\$1.81

The cost per square yard, exclusive of grading the roadway, was:

	Per sq. yd.
1-6 cu. yd. bottoming, at \$1.36.....	\$0.23
1-12 cu. yd. macadam, at \$1.81.....	0.16
Total	\$0.38

Laborers were paid 15 cts. per hr., and teams 25 cts. per hr. The cost of foremen is not included. The cost of the quarrying is given on page 210.

The foregoing relates to trap rock. If limestone or sandstone occurring in thin beds is quarried by wedging, and is roughly scabbled and laid like a paving, the cost of a telford "bottoming" is practically the same as for the slope-wall paving given in section on Masonry. The cost of the macadam surface may be estimated from data given on previous pages.

Cost of Sand-Clay Roads.*—The mixing of sand and clay as a

*Engineering-Contracting, Nov. 28, 1906.

form of road construction has received careful study by the Office of Public Roads, U. S. Department of Agriculture, and a bulletin by William L. Spoon, Road Expert, Office of Public Roads, has recently been issued descriptive of this method of construction. The matter of sand-clay roads is of considerable importance to the Atlantic and Gulf States, where throughout large areas sand and clay are practically the only materials available for road building. In the Southern States a number of sand-clay roads have been built, and they have proved well adapted for light traffic.

The best sand-clay road is one in which the wearing surface is composed of grains of sand in contact in such a way that the voids between the grains are entirely filled with clay, which acts as a binder. Any excess of clay above the amount necessary to fill the voids in the sand is detrimental. All the experiments made by the Office of Public Roads indicate that the materials should not be mixed in a dry state, but should be thoroughly mixed and puddled with water. This is most easily brought about immediately after a heavy rain, the clay having been previously spread and the larger lumps broken up as completely as possible. The surface should then be covered with a few inches of sand and plowed and harrowed thoroughly by means of a turning plow and a cutaway or disc harrow. In cases where the plowing and harrowing are considered too expensive, the mixing may be left to traffic. This, however, leads to a muddy road surface for a long time, although finally it is possible, by a proper distribution of sand upon the clay, to bring about a fairly good result.

Where a slaking clay is used, very much less puddling is required, as there are practically no lumps to be broken up and the mixing can easily be done with the harrow after a rain. Slaking clays do not usually make as effective binders as the more plastic clays, and as a result the road surface becomes more dusty in dry weather. The best kind of clay for this kind of construction is one that slakes sufficiently easily to enable the lumps to be readily broken up, and that at the same time, without being too plastic, has sufficient binding power to cement the grains of sand and form a smooth, impervious surface on the road.

No exact rules can be laid down for calculating in advance the best mixture of clay and sand. An easy method for making a rough estimate of the volume of the clay filler required for any unit quantity of a given sand is given by Mr. Spoon as follows: Two ordinary glass tumblers of as nearly as possible the same size are filled to the brim, one with the dry sand to be tested and the other with water. The water is then poured carefully from the one glass into the sand in the other until it reaches the point of overflowing. The volume of water removed from the glass which was originally full of water can be taken as an approximate measure of the voids in the unit volume of sand contained in the tumbler. A simple calculation will reduce this to percentage volume.

In the construction of sand-clay roads two distinct conditions are likely to be met: The road may have a sandy subsoil, that must be overcome by the addition of clay; or the subsoil may be of clay, and in this case sand must be added to it.

Sand-Clay Construction in a Sandy Subsoil.—In the construction of a sand-clay road upon a sandy subsoil, after the drainage has been provided, the roadbed should be brought to crown. A section of the road nearest the source of the clay is crowned first, and on this section the first load of clay is dumped, each succeeding load being hauled over the preceding, care being taken, however, to spread each dumped load separately and evenly before it is driven over. After the clay has been spread it is covered with a layer of clean sand, and when the road has been opened to traffic additional sand should be added to keep the surface smooth and prevent the formation of mud. If a narrow, single track roadway is to be built, it has been found best to spread the clay to a width of about 12 ft. and to a depth of 6 to 8 ins. in the center, tapering the layer to a thin edge at the sides. After the clay layer is completed and covered with sand, if the clay is plastic and lumpy, it will probably be necessary to plow and harrow it alternately until the lumps are thoroughly disintegrated, advantage being taken of rains to puddle the road surface with a harrow.

More sand must be added if the surface shows a tendency to "ball" and cake, and if, on the other hand, the surface loosens in dry weather, it is due to an insufficient quantity of clay or because the clay lacks binding power.

A roadway 12 ft. wide, with an average depth of 6 ins. of clay, will require 1 cu. yd. of clay to cover $4\frac{1}{2}$ ft. of road length; or 1,178 cu. yds. of clay will be required for one mile of 12-ft. roadway. Mr. Spoon states that the average load has been found to be about $\frac{1}{2}$ to $\frac{3}{4}$ cu. yd., when the haul is over sand, and 1 cu. yd. when the haul is over a dry clay road.

Sand-Clay Construction on a Clay Subsoil.—As in the first case proper drainage must be provided; the road should then be crowned as nearly as possible to the form desired in the finished road. The road surface should have a slope of at least $\frac{1}{2}$ in. per foot. It is much more important to form first this foundation crown with a clay than with a sandy subsoil.

After the foundation has been prepared, the surface should be plowed and harrowed to a depth of about 4 ins., until it is pulverized as completely as possible. It is then covered with 6 to 8 ins. of clean, angular sand, spread so that the layer is thickest at the center of the road.

The first mixing by plow and harrow is done while the materials are still in a comparatively dry state. After the first mixing has been finished the road is finally puddled with a harrow after a rain. In case excess of clay works to the surface, more sand is applied.

When the mixing and puddling has been completed the road is

shaped while it is still soft enough to be properly finished with a scraper and at the same time stiff enough to pack well under the roller or action of traffic.

Cost of Sand-Clay Construction.—The cost of this form of construction varies with the conditions. The following data, given by Mr. Spoon, are based on the assumption that the clay can be procured within a mile of the road that is to be improved, and that the cost of labor is about \$1 per day and teams \$3 per day. On those assumptions the cost of constructing a 12-ft. sand-clay road on a sand foundation, covered with clay to an average depth of 6 ins., would be approximately as follows for a distance of one mile:

Crowning and shaping road with road machines:		Total.
2 teams at \$3, 1 day.....	\$	6.00
1 operator at \$1.50, 1 day.....		1.50
Loading and Hauling:		
Loosening clay with pick and shoveling into wagons, 1,173.33		
cu. yds. at 15 cts.....		176.00
Hauling, 1,173.33 cu. yds. at 23 cts..		269.86
Spreading Clay with Road Machine:		
2 teams at \$3, 3 days.....		18.00
1 operator at \$1.50, 3 days.....		4.50
Shoveling Sand on Clay:		
Estimated at ½ ct. per sq. yd....		35.20
Harrowing:		
1 team at \$3, 2 days.....		6.00
Shaping and Dressing with Road Machine:		
2 teams at \$3, 2 days.....		12.00
1 operator at \$1.50, 2 days.....		3.00
Rolling:		
Estimated at ½ ct. per sq. yd.....		35.20
Total		\$579.26

On this basis the estimated cost per square yard of road surface would be about 8 cts. The cost of building a sand-clay road on a clay foundation would not vary much from the figures given. In fact, the latter form of construction would probably be cheaper.

According to the experience of the Office of Public Roads, the cost of sand-clay construction in the South has been found to range from \$200 to \$1,200 per mile, in most cases running from \$300 to \$800.

A sand-clay road constructed under the direction of the Office at Gainesville, Fla., 1 mile in length, 14 ft. wide, and having a 9-in. sand-clay surface, cost \$881.25 per mile, or 10 cts. per sq. yd. Another sand-clay road built under the direction of the Office at Tallahassee, Fla., 16 ft. wide and surfaced with about 7 ins. of sand-clay mixture, cost \$470 per mile, or about 5 cts. per square yard. In case changes of grade have to be made with consequent cuts and fills, the cost would be proportionately greater than the figures given above.

ROADS, PAVEMENTS, WALKS.

Cost of a Sand-Clay Road in Iowa.*—During the 1908 session of the road school of the State Highway Commission, a mile of sand-clay road was built to test this form of construction for Iowa. The road selected lies partly within the incorporated limits of Waterloo, and was in such bad condition that there was practically no heavy traffic over it. As soon, however, as the road was completed it took all traffic for farmers living northeast of Waterloo, with satisfactory results during the past year. Some of the actual cost figures on the work were as follows:

Amount of clay handled.....	3,124 cu. yds.
Total road covered.....	2,800 lin. ft.
Total road improved.....	5,880 lin. ft.
Width of sections.....	18 ft.
Dept of clay in center.....	18-20 in.
Amount of clay per lin. ft.....	.75 cu. yds.
Average cost per yd. in place including clearing, weed cutting and finishing	41.6 cts.
Average haul	4,420 ft.
Average cost per mile at above figures.....	\$1,650

This latter figure would include cost where the entire mile had to be covered with clay, but in the case of the road at Waterloo only about one-half the entire length improved had to be covered. One-quarter was improved by cutting down a clay hill, the clay being used in filling over the sand, and one-quarter being simply shaped with a road machine. The cost per mile under these conditions would be reduced to about \$1,000. Labor was paid \$2.25 per day and \$5 per day was paid for teams and dump wagons.

Cost of Cinder-Clay Road, Iowa.†—Several miles of road have been constructed of soft coal cinders in and near Council Bluffs, Ia. This material was used owing to the lack of stone suitable for macadam, the limestone in that neighborhood being nearly worthless for that purpose, and suitable stone being far distant. The method of constructing these roads as given in a letter to the editors from Mr. W. F. Baker, Supervisor of Pottawattamie County, Iowa, is as follows: "We use about 800 cu. yds. of cinders per mile and this leaves them about 5 ins. thick and 10 ft. wide upon the surface of the road. We then plow the roadbed to a depth of about 5 ins. below the cinders and 10 ft. wide, thus thoroughly mixing the cinders with the dirt,—about one half of each. We then use a blade grader moving this mixture outward from the center to the depth plowed and 10 ft. wide, finding a smooth hard surface that is rolled thoroughly. We then move this mixture back with our grader, spreading it evenly over this hard surface about 2 ins. thick at a time, following each layer with a heavy roller, thus building up till it conforms to the roadbed upon each side, and sloping from the center outward about 1½ ins. to the foot. Cinders cement equally well with hill clay, black soil, or gumbo, but not so well with sandy soil. We have had this system of road in use over

**Engineering-Contracting*, Aug. 18, 1909.

†*Engineering-Contracting*, July 2, 1907.

one year where there has been exceedingly heavy traffic with narrow tires and we believe it is equal in durability to macadam, much easier and more cheaply repaired and costing not to exceed one-tenth as much in this locality. This roadbed is not only exceedingly hard but rough, so rubber tires do not pick it up, and when displaced with shoe corks, it cements again under pressure, while rain has no effect upon it. This form of road leaves a dirt road on each side for the travel in dry weather, which I considered very important. As to the cost, if you were to pay 15 cts. per yard for the cinders, and then haul them from one to two miles to your road, your road when completed would cost not to exceed \$500 per mile."

Cost of Burnt Clay Roads.*—In some sections of the country clay is the only available material from which roads can be constructed. This is so in large areas in the South, particularly in the valleys of the Mississippi and its tributaries, where sedimentary clays are found very generally. There is little or no sand in these areas and the clays are of a particularly plastic and sticky variety, making traffic in such localities almost impossible during the wet season. To meet this condition the Office of Public Roads, U. S. Department of Agriculture, has made experiments as to the burning of these clays so as to not only destroy the plastic qualities, but also as far as possible to form hard brick-like lumps which should be capable of sustaining traffic. Following these experiments an experimental road was constructed which is proving highly satisfactory. The construction of this type of road as well as the construction of sand-clay roads, is given in a bulletin by William L. Spoon, Road Expert, Office of Public Roads, which has been recently issued by the U. S. Department of Agriculture. In the preparation of the roadbed for burnt-clay roads, the road is graded to an even width between ditches, and is then plowed up as deeply as possible. Furrows are then dug across the road from ditch to ditch, extending through and beyond the width to be burned. If it is intended to burn 12 ft. of roadway, the transverse furrows should be 16 ft. long, so as to extend 2 ft. on each side of the final width of the roadway. Across the ridges formed between these furrows, which should be about 4 ft. apart, the first course of cordwood is laid longitudinally, so as to form a series of flues in which the firing is started. From 15 to 20 of these flues are fired at one time.

Good sound wood, as dry and well seasoned as possible, is used for fuel. But in addition dry brushwood, bark, old fence rails, ties, coal slack, may be used to advantage with the cordwood. The best and soundest cordwood is selected for the first course, and should be laid so that the pieces will touch, thus forming a floor. Another layer of wood is thrown irregularly across this floor, in crib formation, with spaces left between in which the lumps of clay are piled. This clay should be in coarse lumps, so as to allow a draft for easy combustion.

After the lumps of clay have been heaped upon this floor another

*Engineering-Contracting, Dec. 5, 1906.

course of wood is laid parallel to the first. The third layer is placed in exactly the same manner as the first, and each opening and crack filled with brush, chips, or any other combustible material. The top layer of clay is placed over all and the finer portions of the material heaped over the whole structure. This final layer should be taken from side ditches, and may be lumps of all sizes. It is spread evenly over the top in a layer of not less than 6 to 8 ins. Finally the whole is tamped and rounded off so as to hold the heat as long as possible. If coal slack is available two top layers of wood may be left out and the slack thoroughly mixed with the clay. A careful arrangement of the cordwood cribbing to separate the clay is important.

In the practice of the Office of Public Roads, 15 or 20 flues are prepared ready for firing in one section. However, if a large force of laborers is available, a greater number of flues can be fired at one time. The best results are obtained by firing all the flues of a section simultaneously and maintaining the combustion as evenly as possible.

After the firing is completed not only the portion of clay which forms the top of the kiln, but the ridges between the flues should be burned thoroughly, so as to form a covering of burnt clay 10 to 12 ins. in depth, which, when rolled down and compacted, forms a road surface of from 6 to 8 ins. in thickness. If properly burned, the material should be entirely changed in character, and when it is wet it should have no tendency to form mud. When the material is sufficiently cooled the roadbed should be brought to a high crown before rolling, in order to allow for the compacting of the material. This can best be done with a road grader. After this the rolling should be begun and continued until the roadbed is smooth and hard. The finished crown should have a slope of at least $\frac{1}{4}$ in. to the foot.

The main advantages of burning a road over its entire length are that the cost of transporting clay is avoided and that the subgrade of the road is burned as well as the material above.

In giving the cost of burnt-clay construction Mr. Spoon states that it is, of course, impossible to give the cost of a burnt-clay road which will apply to the same work in all sections of the country. Although this form of construction in the South up to the present time has been successful, it cannot as yet be said to have passed the experimental stage. The items of cost of the experimental road 300 ft. long, as constructed at Clarkdale, Miss., are as follows.

30½ cords of wood, at \$1.30 per cord.....	\$39.65
20 loads of bark, chips, etc.....	6.00
Labor at \$1.25 per day and teams at \$3 per day....	38.30
Total cost of 300 feet.....	\$83.95
Total cost per mile at this rate.....	\$1,478.40

Since the above road was built numerous sections of burnt-clay road have been constructed in that locality, and up to the present time only favorable reports regarding them have been received.

Cost of Maintaining Earth Roads by Dragging.*—In a recently issued Farmers' Bulletin, Mr. D. Ward King gives some data on the cost of maintenance of earth roads by dragging. He states that the most elaborate form of split log drag will cost but a few dollars for material and labor, while one man and team can operate it successfully under all usual conditions. Mr. King gives the following figures as showing the cost of maintaining ordinary country roads per mile per year without a drag. They were obtained in Kansas by Prof. W. C. Hoad, of the University of Kansas, in 1906, and were taken from the official records of the counties:

Crawford County	\$52
Douglas County	38
Franklin County	34
Johnson County	48
Neosho County	40
Saline County	43

The average cost is \$42.50 per mile per year, and Mr. King states that it may safely be said that the cost of dragging would be trifling in comparison. In the Report of Highway Commissioner of Maine in 1906 it is stated that the least expense per mile for dragging was about \$1.50; the greatest a little over \$6; the average expense per mile for 5½ miles a little less than \$3. One township in Iowa experimented with the drag on 28 miles of highway for a year. The township paid for the making of the drags and hired men to use them. The total expense, including the original cost of the drags, for the year averaged \$2.40 per mile. A neighborhood of farmers in Ray County, Mo., employed one of their number to drag a 5-mile stretch. He received compensation at the rate of \$3 per day. When the end of the year came and a settlement was made, the cost for the year was found to be \$1.66 per mile. The road is a tough clay. Prof. William Robertson, of the Minnesota Agricultural Station, after a year's experience in dragging a main road made entirely of gumbo without any sand or gravel, and which during the past year has shown no defects either by rutting or development of soft places, fixes the cost of the work at not to exceed \$5 per mile.

Cost of Making a Corduroy Road.†—The old-fashioned corduroy road is still used frequently by contractors where it is necessary to cross a swampy piece of ground with a temporary roadway. Such a road is frequently made of split cedar sticks, about as large as fence posts, cut in 8-ft. lengths, and laid in a close row on the ground. Then earth is shoveled onto the sticks to even up the hollows. A good axman can cut down, saw, split and lay the cedar for a corduroy road at the rate of 40 to 50 lin. ft. (2½ to 3 rods) per day. Hence if he receives \$2 a day, it costs 4 to 5 cts. per lin. ft. of road, or \$200 to \$250 per mile. The foregoing is based on some records of work done under the direction of the managing editor of *Engineering-Contracting*.

**Engineering-Contracting*, May 6, 1908.

†*Engineering-Contracting*, Feb. 6, 1907.

Cost of Gravel Roads, Indiana.*—Mr. Chas. C. Huffine, county engineer of Clinton County, Ind., has given us the following data on the construction of gravel roads in that county:

	Per cu. yd.
Cost of gravel at pit.....	\$0.10
Stripping pit	0.05
Hauling	0.30
Dumping and spreading.....	0.03
Shoveling	0.10
Miscellaneous	0.05
Total	\$0.63

As about 1,800 cu. yds. of gravel are required per mile of road, the cost will be \$1,134. In addition Mr. Huffine estimates the cost of grading the roadbed at \$200 and the cost of bridges and culverts at \$200, making the total cost per mile \$1,534. The above estimate is for bank gravel. The majority of roads built in Clinton County, however, have been made from gravel taken from wet pits, making an additional expense of 25 cts. per cubic yard for dipping or 10 cts. per cubic yard for pumping water, depending on the method by which the gravel is taken out. This would increase the cost of the road \$450 or \$180 per mile, respectively. The above are about the average cost of gravel roads in Clinton County for the past five years. The contract prices for these roads have varied from \$1,750 to \$2,100 per mile. The specifications for the construction of a gravel road in the above county require the roadbed to be graded to a width of 24 ft. and the gravel surfacing to be placed to a width of 9 ft. The gravel is required to be placed 15 ins. deep at the middle and 9 ins. at the side. Common labor in Indiana is paid about 13½ cts. per hour, and about 30 cts. per hour is paid for a two-horse team and driver.

Cost of Gravel Street, Michigan.—Mr. A. W. Saunders gives the following: The gravel was often very wet, puddled in fact; 87 cu. yds. of gravel made 90 lin. ft. of street 6 ins. thick on the center line and 4 ins. thick at the gutter, and 25 ft. wide. The gravel was unloaded from a lighter, 10 men doing the work. Six men in a 10-hr. day loaded 124 cu. yds. on six teams, using eight wagons. Each round trip of team averaged 45 mins. a total of 68 trips being made in a 10-hr. day.

The cost per cubic yard measured loose was as follows:

	Per cu. yd.
Gravel	\$0.850
Unloading, at \$1.75 per day.....	.150
Hauling, at \$4.50 per day.....	.257
Spreading, at \$1.75 per day.....	.087
Superintendence and depreciation.....	.021
Total	\$1.365

Cross Reference on Cost of Grading Roads.—The reader is referred to the section on Earth Excavation and Embankment for the discussion of grading costs.

**Engineering-Contracting*, Dec: 18, 1907.

Cost of Grading a Road, New York.—A stiff clay was ditched and graded for a New York state macadam road near Buffalo, at the following cost per cu. yd.:

	Per cu. yd.
Plowing	\$0.05
Loading into wagons.....	0.12½
Hauling 1,000 ft.....	0.05½
Spreading	0.05
Foreman, supt., timekeeper and water boy.....	0.05
Total	\$0.22

The work was done by contract, and wages were \$1.50 for common laborers, \$4.50 for teams, per 8-hr. day. The clay was loosened with a rooter plow and was hauled in patent dump wagons. This cost is a safe figure for stiff material hauled not more than 1,000 ft.

The cost of grading 2½ miles of road under conditions essentially as above, except that the material was a gravelly soil, was 28 cts. per cu. yd.

Cost of Grading a Road, Maryland.—Mr. W. W. Crosby gives the following:

Grading a road for a 6-in. macadam pavement 14 ft. wide, the whole roadbed being 24 ft. wide, cost 29.6 cts. per cu. yd., not including the cost of "shaping," which was ½ ct. per sq. yd., which is equivalent to adding 4.2 cts. per cu. yd. to the grading cost. The road averaged 1,700 cu. yds. per mile. Work was done by day labor, negro labor at 10 cts. per hr., and team at 40 cts.

Cost of Grading Road With Road Machine, Michigan.—Mr. Frank F. Rogers gives the following data on work done at Port Huron, Mich. A street was to be macadamized with a strip of macadam 9 ft. wide and about 5 ins. thick after rolling. The earth was sand and sandy loam overlying clay. The side ditches had already been made, and the street was already well turnpiked (crowned), so that the grading consisted merely in preparing a bed for the macadam and in making earth shoulders to hold the stone. For this purpose a common road machine was used, first to cut off the high places and fill the hollows by setting the blade at right angles with the center line of the street. Then, to form the shoulders and cut the crown of the subgrade, the blade was set at a slight angle so as to crowd enough earth to one side of the 9-ft. strip, forming first one shoulder, then the other. Stakes were set 1 ft. outside the 9-ft. strip to give line in operating the grader. The edges of the shoulders were afterward trimmed by hand with a shovel while the subgrade was being rolled with a steam roller. The grading cost \$85 per mile in this soft sandy soil, where no ditching or turnpiking was done.

On another stretch of road, in sand, it was necessary to break up, re-grade, and trim the ditches to line, as well as to make the shoulders for the 9-ft. macadam. This cost about \$360 per mile.

Two teams, a driver for each team and another man to operate the grader were used. Each team and driver received \$3.50 for 16 hrs. and the other man received \$1.50.

Average Prices of Pavements in 100 Representative Cities, Together With the Wages of Labor and Prices of Paving Materials.*—In our issue of March 27, 1907, we printed a number of tables showing the character and cost of paving work done in 1906, in a number of representative American cities. In the present issue we present somewhat similar data on the paving work done in 1907 in 100 cities of the United States. No attempt was made to get complete statistics of the United States; the purpose, rather, was to select cities in various sections of the country on the assumption that their practice and activity would represent with approximate accuracy the practice and activity of these sections as a whole.

Perhaps the most interesting of the tables is Table IV, showing the wages of labor and the prices of materials. It will be noted from this that the 8-hr. day does not prevail in all of the cities reporting. Practically all of the Eastern states have an 8-hr. day, while in the Middle West the 10-hr. day seems to be the more common. The rates of wages of labor vary, being lowest in the South and highest in the West. In the New England cities the wages of common labor averaged \$2.00 per day, while in the Middle West the average was \$1.75. The cost of the various paving materials taken in combination with the cost of labor are interesting in as much as they show in a measure the reason for the variation in the cost of the pavement given in the other tables.

Tables V to X, giving the cost of the various kinds of pavement, should be of general interest, although it is evident that no perfectly just comparison can be made without going far deeper into local conditions than the data sent us would permit. In these tables the average price per square yard includes grading, unless stated otherwise.

Cost of Paving in 50 American Cities.†—Tables XI to XIII show the construction and cost of street paving in about 50 representative American cities. These figures were collected by the Committee on Roads and Pavements of the Illinois Society of Engineers and Surveyors and were reported at the annual convention held last week. The records cover macadam, asphalt and brick and block pavements and give the materials used, thickness and cost. The costs given are, of course, costs to the cities and not costs to the contractors. No very accurate general conclusions can be drawn from these records, and in fact this was not the purpose of their collection; they show individual records of city paving work and for this are deserving of careful study. Mr. A. N. Johnson, State Engineer, Illinois, was chairman of the committee, making the report from which the tables are taken.

*Engineering-Contracting, April 1, 1908.

Prices for Estimating Street Work.*—Mr. George P. Carver gives the following prices. They are the prices per square yard on practically all classes of paving, and are used by the engineering department of one of the largest Massachusetts cities for estimating purposes to determine amount necessary for appropriation.

These figures are used, and to the total 10 or 15 per cent is added for incidentals.

The prices in this list are made up from the figures submitted in bids for paving work in that city and are very close to actual figures.

The flagging is granite and North River stone.

The prices given are per square yard unless otherwise stated.

*†Block (granite) paving	\$2.35
*††Block (granite) paving	3.20
**††Block (granite) paving	4.10
Telford macadam, 8 ins. plus 4 ins.	1.50
Macadam, 6 ins.	1.00
**Asphalt, 5-yr. guarantee	3.50
**Asphalt, 10-yr. guarantee	3.75
*Paving with old granite blocks.	1.00
**Repaving with old granite blocks.	2.75
New blocks furnished on ground.	1.35
Brick sidewalks	1.10
Gravel sidewalks	0.40
Crushed stone sidewalks	0.70
New bricks furnished	0.55
Laying bricks flat	0.55
†Relaying old bricks	0.15
Cobble gutters, old cobbles.	1.25
Tar concrete furnished and laid.	1.25
Gravel roadway, 12 ins. deep.	0.55
**Wood paving, furnished and laid.	3.50
*Bit. brick paving	2.50
Concrete base, 6 ins.	0.33
New flagging, furnished on ground.	2.30
†Laying flagging	1.00

Cost of Unloading and Hauling Bricks.—Unloading bricks from a gondola car to wagons, each man will average 100 to 120 sq. yds. of brick per 10-hr. day.

In 8 to 10 mins. a gang of 5 men and the driver will easily load a wagon with enough brick to lay 10 sq. yds., which is equivalent to

* *Engineering-Contracting*, May 16, 1906.

a load of 2 tons. Such a load can be hauled by a team over an ordinary good, level earth street.

In unloading the bricks at the curb line, the driver and another man in the wagon toss brick to two men who stack them up. They will unload the wagon (14 sq. yds.) in 8 to 10 mins.

Summing up we have the following cost of loading and unloading (not including the lost team time):

	Per sq. yd.
0.08 hr. labor loading wagon, at \$0.20.....	\$0.0160
0.05 hr. labor unloading wagon, at \$0.20.....	0.0120
Total	\$0.028

Since the lost team time, while loading and unloading, amounts to about 20 mins. per load, or 2 mins. per sq. yd., we have a cost of 1.4 cts. per sq. yd., when team time is worth 40 cts. per hr.

A team travels $2\frac{1}{2}$ miles per hr., or 220 ft. per min. Hence the cost of hauling, when the load is 10 sq. yds. or 2 tons, is 3.2 cts. per sq. yd. per mile of distance between the car and the place of unloading.

We have a fixed cost of 2.8 cts. for labor of loading and unloading, plus 1.4 cts. for lost team time, or a total fixed cost of 4.2 cts. per sq. yd. Hence the following rule for the cost of hauling brick:

To a fixed cost of 4.2 cts. per sq. yd. add 3.2 cts. per sq. yd. per mile when the load is 2 tons.

By using two extra wagons, one empty wagon at the car being loaded, and one full wagon being unloaded at the street, the item of "lost team time" can be almost entirely eliminated, for a team can be unhitched from an empty wagon and hitched to a loaded wagon in 1 min., and by fastening a chain from the rear of the loaded wagon to the tongue of the empty, the empty can be pulled up alongside the car ready for loading. When this is done, the "fixed cost" is reduced to 2.8 cts. per sq. yd. Then if 3 tons are hauled per load, as is common on city streets, the cost of hauling brick becomes:

To a fixed cost of 2 cts. per sq. yd. add 2 cts. per mile of haul.

The use of extra wagons is particularly desirable when a smaller gang than 5 men is engaged in loading, for with a smaller gang the lost team time would be correspondingly greater if there were no extra wagons.

Gravity Conveyor for Handling Brick to Pavers From Stock Piles Without Breakage.*—Fig. 3 shows a simple device for handling paving brick from stock piles at the sides of the street to pavers, which has been successfully used by Carlson & Thesellus, brick paving contractors, Chicago, Ill., in paving work in Chicago and other western cities. The usual method of handling brick is by wheelbarrows. The barrows are loaded at the stock piles by wheelers, wheeled onto the street and dumped. There the dumped brick are arranged ready to the hand of the pavers by pilers. For say

**Engineering-Contracting*, April 21, 1909.

Fig. 8. Gravity Conveyor for Paving Brick.

three pavers laying 1,500 sq. yds. per day there will be required eight wheelers and four pilers to handle the brick. In addition the loading and dumping of the brick results in more or less breakage. With the device illustrated it has been found easily possible to supply bricks to three pavers laying 1,500 sq. yds. per day with only four men, a saving of eight men over wheelbarrow work.

The general arrangement of the device on the work is shown by Fig. 8. The device is merely a set of conveying rolls. Two boards 6 ins. wide are set parallel and carry between them a train of wood spools. The axles of the spools extend through bushed holes in the side boards and have removable nuts at the ends, which permit oiling. The spools are spaced so as to have a clearance of $\frac{1}{8}$ in. They are ordinary wooden spools, with a barrel $3\frac{1}{2}$ ins. long between shoulders. They are set so that the line of the shoulders is just below the top edges of the side boards; this permits a steel strap guard to be fastened to the top edge of each side board so as to extend inward over the shoulders and prevent dirt and chips from lodging between the ends of the spools and the adjoining side boards. Below the journals the side boards are thinned down so as to permit such debris to fall out easily. The whole construction is very simple and forms, as has been stated, a train of rolls which, when set at an incline, will allow a brick, when set edgewise on the spools, to move from top to bottom by gravity.

The conveyors described above are usually made in 16-ft. lengths. They may, of course, be made longer, but a 16-ft. length is easily carried by one man, and when much longer conveyors are needed two or more 16-ft. sections can be coupled end to end. When used on the street the ends of the conveyors near the sides of the street are supported on standards extending up from small trucks or carriages which travel along the gutter. This method of support can be seen in the illustration. Two conveyors are employed, one extending into the street from each side. The inner ends of the two conveyors meet at the center of the street and the outer ends extend beyond the supporting trucks and the gutters and past the ends of the stock piles. Just back of the trucks there is a hinge in each conveyor which permits the projecting end to be tilted up to clear trees, poles or other obstructions when the conveyors are shifted ahead. The incline given the conveyor is as flat as may be, so that the brick can be put on and taken off the conveyor with as little lifting as possible. An incline of 1 in. to 1 ft. is ample; in fact it has been much flatter on most of the work done by Messrs. Carlson and Theslius. In one case the incline was only 14 ins. in 24 ft.

The method of operating the conveyors is quite clearly shown by the illustration. The loaders take the bricks from the piles and set them edge up and endwise on the spools. The movement of the brick is then by gravity down the conveyor. In putting the brick on the conveyor the loaders take care to place the best or smooth edge up, so that when the pavers take them off they do not have to turn them to find the best edge to come on top. The pavers

grasp a brick in each hand and place both at once. The loaders take care, in placing the brick on the conveyors to keep the supply just ahead of the laying. If the conveyor is kept tight packed with brick all the time, they bind and the paver has to exert more force in lifting them, which reduces his speed.

As stated above, with three conveyors a gang of seven men, four loaders and three pavers, will lay 1,500 sq. yds. of paving a day. This record has been frequently made by the contractors named above. These contractors have patented the device and are putting it on the market. They will furnish these conveyors made up in 16-ft. lengths or longer at \$2 per lineal foot.

Cost of Laying Bricks.—Bricks are ordinarily carried in wheelbarrows from the piles along the curb and dump on the finished pavement behind the bricklayers. The average wheelbarrow load is about 40 "pavers," or 270 lbs., and is seldom more than 45 "pavers," or 305 lbs. Such loads are readily wheeled over level runways and even up a short slope of 1 in 7. A man will readily load a barrow in 1½ mins., at which rate, if he were doing nothing else but load barrows he would average 14,000 "pavers" loaded in 10 hrs. But the men who load the bricks usually wheel them to place and dump them. Where the distance to be wheeled is about 40 ft., it takes about ¾ min. to go and return plus another ¾ min. lost in dumping the barrow and in brief rests; so that a day's work is 10,000 "pavers," or 175 sq. yds., loaded and wheeled 40 ft.

Two men wheeling bricks to each bricklayer is a common ratio, and 300 sq. yds. laid per day by a bricklayer is considered a big day's work, although it is frequently exceeded. This would require the wheeling of 150 sq. yds. per man on wheelbarrow.

Foremen are often very careless in spacing the wagon loads of brick along the curb, so that there are frequently too many bricks at one part of the street, and too few at another. When this is so, more men with wheelbarrows are required to deliver the bricks.

The number of men to each bricklayer is ordinarily about as follows:

	Per day.
1 bricklayer	\$ 2.50
2 men wheeling and delivering bricks.....	3.50
1 man spreading sand cushion.....	2.25
1 man ramming	1.75
1½ men grouting joints with cement.....	2.65
½ man raising sunken brick, etc	0.85
7 men total	\$13.50

When the bricklayer, who really "sets the pace," lays 300 sq. yds. per day, the cost of laying and grouting is $\$13.50 \div 300 = 4\frac{1}{2}$ cts. per sq. yd., to which ½ ct. must be added for foreman and water boy, making a total of 5 cts. per sq. yd. for laying the brick. This is a cost that may be attained under good management, and with skilled men. It is, perhaps, nearer an average to say that 225 sq. yds. per day are commonly laid by each bricklayer, making the cost of laying 6 cts. per sq. yd., exclusive of foreman and

water boy, or 6.6 cts. including them, assuming that a foreman supervises about 20 men, and that wages are as above given.

Summary of Cost of Brick Pavement.—Based upon the foregoing data, we may summarize the cost of a brick pavement, bricks laid on edge, grouted with 1 to 1 cement mortar, as follows:

Materials:

55 "pavers," at \$15.00 per M.....	\$0.825
0.042 cu. yd. sand for cushion $1\frac{1}{2}$ ins. thick, at \$1.00....	0.042
0.004 cu. yd. sand for grouting joints, at \$1.00.....	0.004
0.028 bbl. cement for grouting joints, at \$1.50.....	0.042

Total materials\$0.913

Labor:

Hauling brick 1 mile (3 + 3 cts.).....	\$0.050
Laying brick and grouting	0.050

Total labor	\$0.100
Total materials and labor	\$1.013
$1\frac{1}{8}$ cu. yd. concrete base, at \$3.60.....	0.600
$\frac{1}{2}$ cu. yd. earth excavation, at \$0.20.....	0.100

Grand total\$1.713

The above costs of concrete base and of earth excavation are merely assumed for illustration, the details of those classes of work being given elsewhere.

The cost of filling of the joints of a brick pavement is discussed in detail in the next paragraph.

Cost of Filling Joints of Brick Pavement.—To determine the area of brick pavement occupied by the joints, refer to the table on page 359. It will be noted there, for illustration, that $2\frac{1}{2} \times 8\frac{1}{2} \times 4$ -in. bricks laid on edge require 57.2 bricks per sq. yd. when laid with $\frac{1}{2}$ -in. joints, or 61 bricks if it were possible to lay them so close that there would be no joints. Hence the joints occupy an area equivalent to $61.0 - 57.2 = 3.8$ bricks per sq. yd. But $3.8 \div 61 = 6.2\%$, which is the percentage of area occupied by joints. Since the joints are 4 ins. deep, each sq. yd. of pavement contains $6.2\% \times (4 + 36) = 0.007$ cu. yd. of grout or tar used to fill the joints. If cement grout is used, then the amount of sand and cement per cu. yd. for any specified proportions is ascertained by referring to Tables I and II in the Concrete Section.

Thus, Table I shows that about 4 bbls. of cement and 0.6 cu. yd. of sand are required per cu. yd. of 1 to 1 mortar. Hence a sq. yd. of brick pavement laid with pavers will require 0.007×4 bbls. = 0.028 bbl. cement, and 0.007×0.6 cu. yd. = 0.0042 cu. yd. sand.

In like manner, we find that about $2\frac{1}{2}$ bbls. cement and 0.8 cu. yd. of sand are required per cu. yd. of 1 to 2 mortar. Hence, $0.007 \times 2\frac{1}{2} = 0.0175$ bbl. cement will be required to grout a sq. yd. of brick; and $0.007 \times 0.8 = 0.0056$ cu. yds. of sand.

If paving blocks, $3\frac{1}{4} \times 8\frac{1}{2} \times 4$ ins., are laid with $\frac{1}{4}$ -in. joints, it will be seen on page 359 that 44.5 blocks lay a sq. yd., while without joints it would require 46.9 blocks, or a difference of 2.4 blocks, which is 5.1% of the area. Hence, using the same method of

analysis as above given, it would require $5.1\% \times (4 \div 36) = 0.0057$ cu. yd. of grout or tar to fill the joints. Therefore it would require 0.023 bbl. cement and 0.0034 cu. yd. sand to fill the joints of a square yard of blocks with a 1 to 1 grout. With a 1 to 2 grout, it would require 0.016 bbl. cement and 0.0046 cu. yd. sand per sq. yd.

If a tar or pitch filler is used, the $3\frac{1}{2} \times 8\frac{1}{2} \times 4$ -in. "pavers" will require 0.007 cu. yd., or 0.19 cu. ft. of tar per sq. yd. Since there are $7\frac{1}{2}$ gals. per cu. ft., this is equivalent to 1.3 gals. per sq. yd. Tar is usually sold in 52-gal. barrels, but the size of the barrel should always be specified.

If $3\frac{1}{2} \times 8\frac{1}{2} \times 4$ -in. "blocks" are used, 0.0057 cu. yd., or 0.15 cu. ft., or 1.1 gal. of tar will be required per sq. yd.

Tar has a specific gravity of 1.25, and therefore weighs 78 lbs. per cu. ft., or a trifle more than 10 lbs. per gal.

As above given, the labor of grouting joints of "pavers," including mixing the Portland cement and sand and brooming it into the joints, is less than 1 ct. per sq. yd., where the men work at all vigorously, but even this is equivalent to $\$0.01 \div 0.007$ cu. yd. = \$1.40 per cu. yd. of cement grout, and is, therefore, susceptible of considerable reduction, as will be seen by subsequent examples.

The labor cost of melting and pouring tar into joints is usually about 1 ct. per gal., when wages are \$1.75 per 10 hrs.

Number and Weight of Paving Brick Per Square Yard.—The so-called "standard brick" for house building is $2\frac{1}{4} \times 8\frac{1}{4} \times 4$ ins., and for a time brick for paving purposes were also made of the same dimensions. Within recent years the size of the standard brick for paving purposes has become $3\frac{1}{2} \times 8\frac{1}{2} \times 4$ ins., and such bricks are commonly called "pavers." It takes 52 to 57 of these "pavers" per sq. yd. A larger size, $3\frac{1}{2} \times 8\frac{1}{2} \times 4$ ins., is also much used, and is known as "block." Some variations from these dimensions occur, as in Hallwood block, which is $3 \times 9 \times 4$ ins.; and as neither the engineer nor the contractor can be sure of the exact size of brick that will be delivered, it is always necessary to secure from manufacturers a statement as to the sizes they make.

When the sizes are known there is a factor of uncertainty to the inexperienced, and that is the thickness of the grouted or tarred joints between bricks as ordinarily laid. I have found as the average of a large number of measurements that the thickness of the average joint is about $\frac{1}{8}$ in., unless the "pavers" are made with projecting lugs to give a wider joint.

The following table gives such data as will ordinarily serve in estimating the number of brick that will be required. Brick are occasionally laid with extremely close joints about one-sixteenth inch, in which case about 3% more "pavers" laid on edge will be required than given in the table, but close laying is not only expensive work for the contractor, but objectionable also in that it is then impossible to fill the joints perfectly.

For street pavements the bricks or blocks are laid on edge (mak-

ing a brick pavement 4 ins. thick), but for sidewalks they are usually laid flatwise. I believe that in residence streets the bricks should usually be laid flatwise for true economy's sake.

Size of Brick.	No. of Brick Per Square Yard.	
	With $\frac{1}{8}$ -in. Joints.	No Allowance for Joints.
$2\frac{1}{4} \times 8 \times 4$, laid flatwise	33.7	40.5
$2\frac{1}{4} \times 8 \times 4$, laid edgewise	67.1	72.0
$2\frac{1}{4} \times 8\frac{1}{2} \times 4$, laid flatwise	37.6	39.3
$2\frac{1}{4} \times 8\frac{1}{2} \times 4$, laid edgewise	65.1	69.8
$2\frac{1}{4} \times 8\frac{1}{2} \times 4$, laid flatwise	36.4	39.8
$2\frac{1}{4} \times 8\frac{1}{2} \times 4$, laid edgewise	67.2	61.0
$3\frac{1}{4} \times 8\frac{1}{2} \times 4$, laid flatwise	36.4	32.1
$3\frac{1}{4} \times 8\frac{1}{2} \times 4$, laid edgewise	44.6	46.9
$3 \times 9 \times 4$, laid flatwise	34.4	36.0
$3 \times 9 \times 4$, laid edgewise	45.6	48.0

Having obtained the price per thousand (M) for the paving brick, f. o. b. factory, and freight rate to destination, the weight of the bricks must be known to estimate total cost f. o. b. cars at destination. The specific gravity of paving brick ranges from 1.9 to 2.7. Tests of 12 Ohio makes show a range of 1.95 to 2.25.

Assuming a specific gravity of 2.2, a square yard of brick pavers 4 ins. thick would weigh 385 lbs., and a square foot would weigh 43 lbs., as laid with $\frac{1}{8}$ -in. joints. Whence, by taking from the bidding sheet the number of square yards of pavement and multiplying by 385, the total weight is readily ascertained; or, for all practical purposes, divide the number of square yards by 6, and the quotient will be the number of short tons of freight.

It is convenient to remember that a "paver" ($2\frac{1}{4} \times 8\frac{1}{2} \times 4$ ins.) weighs about 6 $\frac{1}{2}$ lbs. and a "block" ($3\frac{1}{4} \times 8\frac{1}{2} \times 4$ ins.) weighs 8 $\frac{1}{2}$ lbs. These are actual averages of several makes of New York State bricks that I have used.

Cost of a Brick Pavement, Champaign, Ill.—Mr. Charles Apple gives the following data on the cost of a brick pavement laid in 1903 at Champaign, Ill. The work was done by contract, the contract price for grading being 23 cts. per cu. yd., and for brick pavement on concrete base, \$1.29 per sq. yd.

The grading was done with drag-scoop scrapers, wheel-scrapers and wagons, each being used as demanded by the length of haul. Earth was loosened with plows to within 3 ins. of subgrade and this last layer then removed with pick and shovel.

The cost of removing the last 3 ins. was 2 cts. per sq. yd. (or 24 cts. per cu. yd.) with labor at \$1.75 per day of 10 hrs. There was a total of 26,715 cu. yds. of grading, and there were 38,504 sq. yds. of pavement.

The subgrade was compacted with a horse-roller weighing 150 lbs. per lin. in. at an average cost of about 0.05 cts. per sq. yd.

The concrete foundation was 6 ins. thick, composed of 1 part natural cement, 3 parts of sand and gravel, and 3 parts of broken stone. All the materials were mixed with shovels, and were thrown into place from the board upon which the mixing was done. The material was brought to the steel mixing board in wheel-

barrows from piles where it had been placed in the middle of the street, the length of haul being usually from 20 to 60 ft.

When the concrete base had set, a sand cushion $1\frac{1}{4}$ ins. thick was placed upon it, and upon this the brick wearing surface was laid.

The cost of the brick wearing surface is given in the following table, and is based upon the assumption that 1,000 paving blocks will lay 25 sq. yds. of pavement, or 40 blocks per sq. yd. This ratio was determined by actual count after the pavement was laid. To this cost will have to be added something for rejected bricks, the amount depending upon how closely the inspection is done at the kilns.

COST OF 6-IN. CONCRETE BASE FOR PAVEMENT.

	No. of men.	Sq. yds. per day.	Total wages.	Cost per sq. yd.
Rolling subgrade (1 roller, 2 teams, 1 driver).....	1	8,000	\$ 4.75	\$0.0006
Mixing and tamping concrete:				
Turning with shovels	6	18.00
Throwing into place.....	4	3.00
Handling cement	2	3.50
Wetting with hose	1	1.75
Tamping	2	3.50
Grading concrete	1	1.75
Wheeling stone	6	10.50
Wheeling gravel	4	7.00
Foreman	1	4.00
Total	27	900	\$52.90	\$0.0580
Total labor per sq. yd.....				\$0.0585

Materials:

0.2 bbl. cement, at \$0.50.....	\$0.10	
0.1 cu. yd. sand and gravel, at \$1.00.....	0.10	
0.1 cu. yd. broken stone, at \$1.40.....	0.14	\$0.2400
Total for material and labor per sq. yd.....		\$0.2985

This is practically 40 cts. per sq. yd., or \$2.40 per cu. yd. of concrete for materials and labor. It will be noted that the labor cost of making and placing the concrete was only 35 cts. per cu. yd., average wages being nearly \$1.85 a day. Excluding the foreman, the 26 men placed 900 sq. yds. or 150 cu. yds. per day, which is nearly 6 cu. yds. per man. This record is so abnormally high that I am satisfied the concrete did not measure 6 ins. thick, as stated by Mr. Apple. Certainly 0.2 cu. yd. of stone and sand combined could not make a sq. yd. of 6-in. concrete. It is more than likely that the compacted concrete actually did not measure much more than 4 ins. thick.

The cost of hauling and laying the brick blocks (40 per sq. yd.) was as follows:

Hauling Brick:	Per sq. yd.
0.01 day labor loading wagons from car, at \$1.75.....	\$0.0175
0.08 day team hauling, 1 mile at \$3.00.....	0.0240
0.008 day labor unloading at curb line at \$1.75.....	0.0140
Total, hauling brick	\$0.0555

Laying Brick:

0.0033 day labor, spreading sand cushion, at \$1.75.....	\$0.0057
0.0066 day wheeling brick to layers, at \$1.75.....	0.0115
0.0033 day bricklayer, at \$2.50.....	0.0083
0.0022 day labor, sweeping and filling joints with sand, at \$1.75	0.0039
0.0012 day team rolling pavement, at \$3.00.....	0.0037
Total, laying brick.....	\$0.0331
Grand total, labor, hauling and laying.....	\$0.0886

Materials:

0.0277 cu. yd. sand cushion (1 in.), at \$1.00.....	\$0.0277
40 brick block f. o. b. destination, at \$16.00 per M.....	0.6400
0.0023 cu. yd. sand filler, at \$1.00.....	0.0023
Total materials	\$0.6700

The following is a summary of the foregoing:

	Per sq. yd.
0.425 cu. yd. grading, at \$0.23.....	\$0.1000
0.167 cu. yd. concrete base	0.3985
Brick and sand cushion.....	0.6700
Hauling brick	0.0555
Laying brick	0.0331
Grand total	\$1.2571

The contract price was \$1.29. Note that the joints were filled with sand and not with grout.

It will be seen that each man loading blocks from car to wagon averaged 100 sq. yds., or 4,000 blocks, per 10-hr. day; and that each man unloading wagons averaged 125 sq. yds., or 5,000 blocks per day. Each bricklayer averaged 300 sq. yds. and each man wheeling bricks to the layer averaged 150 sq. yds.

Cost of 80,000 Square Yards of Brick Pavement, Iowa.—The following is quoted from *Engineering-Contracting*, June 23, 1909. During 1905 and 1906, a large amount of brick paving and cement curb was built at Centerville, Ia., by contract. Mr. M. G. Hall required the inspectors to keep a careful force account of the work done, and the following data are a summary of the records thus gathered.

Purinton paving bricks were laid on a concrete base, with a 1½-in. sand cushion between. The joints were filled with a 1:1 cement grout. Expansion joints of asphalt filler were provided from curb to curb, every 50 ft., and along each curb. The following costs do not include grading.

The concrete base was a 1:3½:6 mixture and it was machine mixed. There appears to have been a serious error made either in recording or in calculating the amounts of cement, sand and broken stone used, for, as will be seen below, Mr. Hall's data show about two-thirds as much of each of these materials per cubic yard as are required by a 1:3½:6 mixture. Mr. Hall's data were originally published in "Engineering News" April 2, 1908, and were not there analyzed as we have analyzed them below, which probably accounts for his failure to discover the discrepancy. This emphasizes the importance of using the cubic yard as

the unit in checking up costs of concrete, instead of relying solely upon the square yard.

Our analysis of the cost of the 5-in. concrete base, for three jobs aggregating 58,000 sq. yds., shows the following:

	Cts. per sq. yd.
Sand wheelers, at 20 cts. per hr.....	12.24
Concrete wagons, at 40 cts. per hr.....	8.42
Men on mixer, at 22½ cts. per hr.....	5.62
Spreaders, at 22½ cts. per hr.....	5.47
Tampers, at 20 cts. per hr.....	1.93
Water boy, at 10 cts. per hr.....	0.72
Extra men, at 20 cts. per hr.....	1.93
Foreman, at 30 cts. per hr.....	1.93
Coal for mixer, at \$2.50 per ton.....	1.58
Total labor	\$9.84

This is practically 40 cts. per cu. yd., exclusive of interest, depreciation and repairs on mixer. Since the concrete was 5 ins. thick, divide any of the above items by 7.5 to get the cost per square yard.

According to Mr. Hall's records, the cost of materials was as follows, when reduced to the cubic yard basis:

	Per cu. yd.
0.56 bbl. cement, at \$2.00.....	\$1.12
0.40 ton sand, at \$0.70.....	0.28
0.52 cu. yd. stone, at \$1.20.....	0.62
Hauling cement	0.02
Hauling sand	0.14
Hauling stone	0.29
Total materials	\$2.47

The sand weighed 2,700 lbs. per cu. yd., and the stone weighed 3,626 lbs. per cu. yd.

Since the materials would have to be about 50 per cent more than above given to make a cubic yard of concrete tamped in place, there is evidently an error, and the cost of materials, at the unit prices given, would be about \$3.70 per cu. yd., instead of \$2.47.

The cost of laying 58,000 sq. yds. of brick pavement was as follows:

	Cts. per sq. yd.
Brick wheelers, at 20 cts. per hr.....	1.52
Bricklayers, at 22½ cts. per hr.....	0.88
Men spreading sand, at 22½ cts. per hr.....	1.05
Water boy, at 10 cts. per hr.....	0.15
Other men, at 20 cts. per hr.....	0.96
Foreman, at 30 cts. per hr.....	0.41
Total	4.97

By dividing the square yard cost of any item into the corresponding rate of wages, the number of square yards per hour is obtained. Thus, each bricklayer laid $22.5 \div 0.88 = 25.6$ sq. yds. per hr., or 256 sq. yds. per day. Since there were 53 bricks per sq. yd., this is equivalent to 13,568 bricks per bricklayer, which is an excellent output.

On another job, where 26,800 sq. yds. were laid, the cost of laying was as follows:

	Cts. per sq. yd.
Brick wheelers, at 20 cts.....	1.06
Bricklayers, at 25 cts.....	0.75
Brick handlers, at 20 cts.....	0.28
Men spreading sand, at 25 cts.....	0.76
Men wheeling sand, at 20 cts.....	0.06
Patchers, at 20 cts.....	0.21
Water boy, at 10 cts.....	0.28
Other men, at 20 cts.....	0.21
Foremen, at 30 cts.....	0.22
Total	3.70

Here each bricklayer averaged 830 sq. yds. per 10-hr. day; and, as there were 56 bricks per sq. yd., this is equivalent to 18,480 bricks per bricklayer per day. There was a car track down the center of this street.

The cost of the bricks ranged from 76½ to 80 cts. per sq. yd., the following being a fairly typical cost of the materials and labor:

	Per sq. yd.
53 bricks, at \$15 per M.....	\$0.800
Hauling bricks	0.035
Sand for 1½ in. sand cushion, at 9¢ cts. per cu. yd. delivered	0.041
Total materials	\$0.876
Labor laying brick, as above detailed.....	0.050
Total	\$0.926

The joints were filled with a 1:1 cement grout, the cost of which was as follows for 58,000 sq. yds.:

	Cts. per sq. yd.
Screening sand, at 20 cts. per hr.....	0.05
Dry mixers, at 22½ cts. per hr.....	0.15
Wet mixers, at 30 cts. per hr.....	0.20
Rubbers, at 20 cts. per hr.....	0.43
Wheelers, at 20 cts. per hr.....	0.12
Other men, at 20 cts. per hr.....	0.02
Water boy, at 10 cts. per hr.....	0.04
Foreman, at 40 cts. per hr.....	0.14
Total labor	1.17
0.017 bbl. cement, at \$2.00.....	3.40
0.034 ton sand, at \$1.05.....	0.36
Grand total	4.92

On the 26,800 sq. yd. job the labor of grouting was only 0.9 cts. per sq. yd.

The cost of the expansion joints (every 50 ft. and along each curb) was as follows per sq. yd. of pavement:

	Cts. per sq. yd.
Labor, at 20 cts. per hr.....	0.82
Pitch, at \$4.80 per bbl.....	0.89
Total	1.21

Summing up we have:

	Per sq. yd.
Concrete, labor	\$0.06
Concrete materials (too low).....	0.34
Bricklaying, labor	0.06
Brick and sand cushion.....	0.88
Grout, labor	0.01
Grout, materials	0.04
Expansion joints, labor and materials.....	0.01
Grand total	\$1.39

For costs of cement curb on this job, see page 449.

Cost of Laying Brick Pavement, Gary, Ind.*—Mr. E. M. Schedon gives the following. In 1908, Madison street was paved by contract for 3,800 ft. long by 38 ft. wide. The brick pavement was laid on a natural sand base, and grouted with cement. Common laborers received \$2 per 10 hrs. The labor cost of laying the brick, not including the cost of hauling the brick to the street, was as follows:

	Per sq. yd.
0.00255 day labor, preparing subgrade, at \$2.00.....	\$0.0051
0.0194 day labor, carrying bricks, at \$2.00.....	0.0388
0.00318 day bricklayers, at \$3.50.....	0.0112
0.0002 day team, rolling, at \$5.50.....	0.0011
0.0026 day labor, grouting, at \$2.00.....	0.0072
Total labor, 16,800 sq. yds.....	\$0.0624

It will be noted that there were 6 men carrying brick to each bricklayer, and that each bricklayer laid ($\$3.50 \div \0.0112) 312 sq. yds. per day. This is an excellent output for the bricklayers, but a very poor showing for the men who delivered the brick, apparently due to the fact that they did not use wheelbarrows.

Cost of Laying Bricks, New York State.—On one job, 30,000 "pavers" were laid per day by the gang of 4 bricklayers and 16 men, or 182 sq. yds. per bricklayer. The management was fairly good, but the bricklayers worked with no energy. The other men worked well.

	Per sq. yd.
4 pavers, at 25 cts. per hr., each.....	1.9
3 laborers wheeling, at 15 cts. per hr.....	0.8
1 laborer spreading sand, at 15 cts. per hr.....	0.8
3 laborers grouting, at 15 cts. per hr.....	0.9
3 laborers ramming, at 15 cts. per hr.....	0.6
1 laborer raising sunken brick, at 15 cts. per hr.....	0.8
1 foreman, at 30 cts. per hr.....	0.6
Total	6.3

Bricks Laid Per Day Per Man, Jackson, Mich.—In paving a street with shale brick, at Jackson, Mich., in 1895, there were about 200,000 bricks used for 3,500 sq. yds., or 57.1 bricks per sq. yd. The bricks were $2\frac{1}{4} \times 4\frac{1}{2} \times 8$ ins., with rounded corners. On a street 42 ft. wide, 6 bricklayers, supplied with brick by helpers, laid 70,000 bricks in 9 hrs. or 11,666 bricks, or 304 sq. yds., per

*Engineering-Contracting, Oct. 14, 1908.

bricklayer. The ordinary average, however, was 7,000 bricks, or only 123 sq. yds. per bricklayer per day. Note that the average day's output was only about two-thirds the best day's output. It is evident that these bricklayers did not exert themselves, for even their best day's record of 204 sq. yds. per layer per day lacks 50% of being as large a day's work as is recorded elsewhere in this book.

Twelve boys filled the joints with tar. To do this a cone-shaped pouring can was used. There was a stopper in the point of the cone, controlled by a rod leading to the hand of the workman.

Cost of a Brick Pavement in Minneapolis.—Mr. Irving E. Howe gives the following data on laying 17,000 sq. yds. of brick pavement in 1897. The work was not done by contract, but by day labor. Six weeks were required with a force of about 65 men. An old cedar block pavement on a plank foundation had to be removed, and the street graded. The subgrade was rolled with a 7-ton horse roller. A 6-in. concrete foundation was then laid, in proportion of 1 natural cement, 2 sand, 5 broken stone. There were required 1.16 bbls. of natural cement per cu. yd. of concrete, at 76 cts. per bbl. The stone cost \$1.15 cts. per cu. yd. delivered, and the sand cost 30 cts. per cu. yd. delivered. The total cost of the concrete laid was \$2.80 per cu. yd. Laborers mixing received \$1.75 per day. The Purlington Paving Brick Co., of Galesburg, Ill., furnished 193 car loads of brick, $2\frac{1}{4} \times 4 \times 8$ -in. size, guaranteed to lay 56 to the sq. yd., costing the city \$15.50 per M, or 87 cts. per sq. yd. on the cars at Minneapolis. The manufacturers guaranteed the bricks for ten years. A 1-in. sand cushion was laid on the concrete. To secure a perfect crown 1-in. strips of wood were nailed to the concrete every 12 ft., from curb to curb. An iron shod straight edge or scraper was placed on these strips and dragged across the street to bring the sand cushion to a perfect surface. Then one of the wood strips was pulled up and moved ahead. After a block of bricks had been laid, they were rolled with a roller, broken bricks replaced, and the joints grouted under a special contract of $17\frac{1}{2}$ cts. per sq. yd. for the grouting. Exclusive of this grouting the actual cost per square yard was as follows:

	Per sq. yd.
Removing old cedar paving.....	\$0.035
Grading	0.032
Concrete, natural cement, 6 ins. thick.....	0.467
Planking over concrete, lumber, etc.....	0.008
56 bricks, at \$15.55 per M.....	0.870
Hauling brick	0.038
Sand cushion, 1-in., at 65 cts. cu. yd.....	0.018
Laying brick	0.032

Total per sq. yd. (not including grout).....\$1.500

The pavers received \$2 a day, laborers \$1.75, teams \$3.50. It will be noticed that the hauling cost 48½ cts. per M of bricks.

Cost of a Brick Pavement, Memphis, Tenn.—Mr. Niles Meri-

wether gives the following data on the cost of 1,300 sq. yds. of brick pavements laid by day labor (probably colored) in 1893:

<i>Concrete base (8-in.):</i>		Per sq. yd.
Natural cement, at \$0.74 per bbl.....		\$0.19 $\frac{1}{2}$
Sand, at \$1.25 per cu. yd.....		0.07 $\frac{1}{2}$
Broken stone, at \$1.87 per cu. yd.....		0.35 $\frac{1}{2}$
Labor hauling stone and making concrete.....		0.15 $\frac{1}{2}$
Total concrete		\$0.68
Sand cushion		0.07
82 paving bricks, at \$18.20 per M.....		1.13
1-25 bbl. pitch, at \$5.25		0.21
Sand used in pitching		0.01
Labor paving and pitching.....		0.15
Total		\$2.35
Grading and removing old material.....		0.23
Grand total		\$2.58

The cost of curbs distributed over the pavement added 10 cts. more per sq. yd. Common laborers were used to lay the bricks, at \$1.25 to \$1.50 per day of 8 hrs. The mortar for concrete was mixed 1:2, and enough mortar used to fill the voids in the stone. It took 1.36 bbls. of Louisville cement per cubic yard of concrete. On three other jobs of about the same size, the costs were practically the same as above. On one street Hallwood blocks were used, requiring 50 blocks per sq. yd., and 1 bbl. of pitch for every 25 sq. yds. On one job, where Virginia paving bricks were used 56 bricks were required per sq. yd., and the labor cost of laying the brick and pitching the joints was 11 cts. per sq. yd.

It will be noted that the cost of materials was unusually high, and that the labor was not efficient.

Cost of Brick Pavement, Baltimore, Md.—In *Engineering-Contracting*, Aug. 18, 1909, was published an article giving the costs of various kinds of pavements laid in 1908 by forces in the employ of the city of Baltimore. I give the following excerpts merely to show the enormously high costs that invariably occur when such work is done by city day labor instead of by contract.

In laying one brick pavement, the labor of mixing and placing the 6-in. concrete base was \$0.217 per sq. yd., or \$1.30 per cu. yd. of concrete. It never costs a capable contractor more than half this, even when he does not use a concrete mixer, and I have known many contractors to mix and lay concrete for 5 cts. per sq. yd., 8 ins. thick, or \$0 cts. per cu. yd., when a machine mixer was used, as recorded subsequently in this book.

In laying the bricks for this same street, the labor cost \$0.342 per sq. yd. This does not include \$0.096 per sq. yd. for hauling the brick. Brick blocks were used, averaging about 40 per sq. yd., and costing \$25 per M., or \$1.00 per sq. yd.

On another street (3,400 sq. yds.) the "vitrified brick paving, labor and materials" cost \$1.56 per sq. yd. Since brick cost \$1 per sq. yd. and paving sand cost \$0.65 per cu. yd., it is evident that the labor item of laying the brick was even greater than on the other street above given. The \$1.56 does not include the 6-in. con-

crete base, which cost \$0.676 per sq. yd., nor the excavation, which cost \$0.099 per sq. yd.

Almost as bad an example of the inefficiency of the day labor system is given in the next paragraph.

Cost of Removing, Chipping Off Tar and Relaying Brick.—It is frequently desirable to know what the cost will be of taking up, cleaning old brick and relaying. A gang of men, working leisurely, "by the day for the city," accomplished the following in Rochester, N. Y. Each laborer chipped the tar off 500 to 700 bricks in eight hours. Replacing a strip of pavement 4 ft. wide over a sewer required a gang of 17 men, employed as follows, after the pavement had been removed and concrete relaid:

	Wages for 8 hrs.	Cost per sq. yd.
3 men tooting or chipping out bats.....	\$ 4.50	\$0.08
6 pavers	15.00	.25
2 men furnishing brick.....	2.00	.05
2 men ramming, etc.....	2.00	.05
4 men melting and pouring tar.....	6.00	.10
Total	\$31.50	\$0.53

The average per 8-hr. day by the above gang was 60 sq. yds., the best day's work being 70 sq. yds.

It seems almost incredible that the cost of such repaving was 53 cts. a sq. yd., but it well illustrates the inefficiency of day labor for a city.

Cost of Chipping Tar Off Bricks.—When a brick pavement with tar joints is taken up, the tar must be chipped off the old bricks before re-laying them. This is usually done with a hatchet, after cooling the bricks in a bucket or tub of water. As an average of a good many thousand brick thus cleaned, I found that one laborer, working deliberately, could be counted upon to clean 80 bricks per hour. With wages at 15 cts. per hr., this is equivalent to \$2.50 per M for cleaning the bricks.

Cost of Removing and Replacing a Brick Pavement.—Mr. C. D. Barstow gives the following relative to removing a strip of brick pavement 3 ft. wide and 373 ft. long, preparatory to digging a trench. The pavement was laid on a concrete base 7½ ins. thick. The laborers were negroes, and the work was done in 1892 in a Southern city. Laborers received \$1.25 per 10 hrs., and white foreman received \$3. The cost was as follows per sq. yd.:

<i>Removing brick and concrete:</i>		Cts. per sq. yd.
Laborer, at \$1.25.....		7.0
Foreman, at \$3.00.....		1.2
Total		8.2
<i>Relaying concrete:</i>		
Laborer, at \$1.25.....		7.9
<i>Relaying brick:</i>		
Laborer, at \$1.25.....		4.6
Bricklayers, at \$2.00.....		6.5
Bricklayers' helpers, \$1.75.....		2.8
Total relaying brick.....		13.8

Materials:

14 new brick, at 1½ cts.....	21.0
0.12 cu. yd. sand, at \$1.00.....	12.0
0.15 bbl. cement for concrete, at \$1.20.....	18.0
Total materials	51.0

Summary:

Removing brick and concrete.....	8.2
Relaying concrete	7.9
Relaying brick	13.8
Materials	51.0
Grand total	80.9

Cost of Laying a Stone Block Pavement, St. Paul.*—While granite block pavement is much less popular now than it was a few years ago, it is not likely that stone block pavements will disappear from use entirely for many years to come. This is particularly true of cities where sandstone of good quality is available for pavements. The Medina sandstone of central New York is a justly popular pavement for business streets. This sandstone is extremely dense and tough, having been partly metamorphosed until it is almost a quartzite. A very similar sandstone is found in Minnesota and is extensively used in St. Paul and Minneapolis.

Neither the Medina sandstone nor the Minnesota sandstone is open to the objection that may be raised against granite or trap rock blocks on the score of slipperiness. Both granite and trap rock wear smooth and glassy under traffic, and the corners of the blocks become rounded. But the sandstones just mentioned always remain gritty and never wear smooth, nor do the corners of blocks become rounded. In fact, when the joints are filled with Portland cement grout, a good sandstone pavement appears like one block of solid stone after it has been in use a while; yet it offers an excellent foothold for horses in spite of the apparent absence of joints. These facts are stated in justification of an article on a class of pavement which has been called out of date. It is altogether likely that New York City itself, which has tried and is still trying so many experiments with paving materials, will some day give Medina sandstone the trial that it deserves as a pavement for heavy traffic.

On the steep streets of Tacoma, Wash., sandstone block pavements are being laid, but the sandstone does not appear to be of as good a quality as Medina sandstone. Nevertheless it seems worth a trial, for asphalt is too slippery for such steep grades as are encountered in certain of the Tacoma streets.

Whatever may be the ultimate history of stone block pavements, it is evident that many city engineers and contractors will have to estimate the cost of laying such pavements, and for their benefit the following data are offered:

In the work to be described a base of Portland cement concrete

**Engineering-Contracting*, Oct. 3, 1906.

(1:3:6) was laid in the usual manner, and a sand cushion spread over the concrete. The sandstone blocks were hauled in wagons and tossed out into the street, instead of being piled on the sidewalk along the curb, as is often done. A considerable saving in the cost of laying is effected by throwing the stone blocks upon the concrete in advance of the paving gang, and a somewhat larger saving would be possible if dump wagons were used. If the street is about 40 ft. wide, the stone blocks are preferably piled in four long piles parallel with the curbs, as shown in Fig. 9. No attempt is made to stack the blocks up regularly, but they are merely tossed out of the wagons. A space is left between the piles so that strings can be stretched to guide the pavers in laying the blocks to grade.

To insure laying the pavement with the proper crown, three sight rods were made. Two of them were like T squares, made of a wooden leg $\frac{1}{2} \times 2$ ins. with a crosspiece at the top. The other sight rod was made so as to telescope, as shown in Fig. 10, and had a leg about 1 in. square that was provided with a groove on one side for a distance 2 ft. below the crosshead. In this groove a 2-ft. rule was set, thus countersinking the rule so that its face was flush with the face of the leg. When this sight rod is extended so that the upper half of the 2-ft. rule is visible, the length of the rod is 4 ft., which is precisely the length of each of the other two sight rods. Before using the rods, a red or blue chalk line is struck with a chalked string on the face of each curb exactly at the finished grade of the pavement. Then at intervals along the curbs, paving blocks, B_1 , B_2 , B_3 and B_{10} , are temporarily set so that their upper faces are at grade. A sight rod is then held on each of the blocks, B_1 and B_3 , at each curb, and the telescopic sight rod is held on a block, B_2 , one-quarter of the distance across the street, as shown in Fig. 10. The telescopic leg of this sight rod is lowered enough to give the drop that secures the exact crown to the pavement shown in the specified cross-section, and the rod is clamped with the thumb screw. The paving block, B_2 , is then raised or lowered until the tops of the three sight rods are exactly on line. Then paving blocks B_4 and B_6 are likewise put on grade; strings are then stretched from these blocks back to surface of the completed pavement. With these three strings to guide them, the pavers can readily lay the pavement exactly to grade. It is obvious that where paving materials are piled up in the street, it would be impracticable to use a straight edge from curb to curb, hence the necessity of some such method as the one just described.

On this particular piece of work each stone block averaged $6 \times 8 \times 9\frac{1}{2}$ ins. and weighed nearly 30 lbs. A wagon load averaged 200 blocks, or $\frac{1}{2}$ tons. Slat bottom wagons were used. This load was hauled over hard earth roads for much of the distance, and over the sand cushion on the concrete base.

The blocks were delivered in gondola cars, and unloaded from the cars into the wagon by two men, assisted by the driver. About half a wagon load (100 blocks) were tossed from the car into the

Fig. 9. Method of Laying Stone Blocks.

wagon box, the driver and the two men standing in the car. Then the driver would get into the wagon and pile up the rest of the blocks with some regularity as fast as the two men would pass them out to him. When the men were tossing the blocks into the wagon, each man averaged 14 blocks per minute when all he had to do was to stoop to pick up a block, but when it became necessary to walk to the opposite side of the car to get the blocks, each man would pick up and deliver only 7 blocks per minute. Under the latter condition the two men in the car would hardly keep the driver busy stacking up blocks in the wagon, yet a short-sighted foreman would have had one man in the wagon to each man in the car. With wagons coming along at regular intervals, the two men aided by the driver would load a wagon every 10 minutes.

In unloading the wagon on the street, one man and the driver consume about 5 minutes, each man tossing out 20 blocks per minute. To allow for slight delays in waiting for other wagons, etc., about 20 minutes should be taken as the average time consumed

Fig. 10. Telescopic Sight Rod.

in loading and unloading the 200 blocks in each wagon. With wages of laborers at 20 cts. per hour, and team with driver at 45 cts. per hour, the fixed cost of loading and unloading (including lost team time) is 35 cts. per wagon load, or \$1.75 per 1,000 paving blocks. The rule for determining the cost of loading, unloading and hauling is, therefore, as follows:

To a fixed cost of \$1.75 per 1,000 blocks, add \$1.50 per mile of distance between the car and the point of delivery on the street.

Since it takes about 20 of these paving blocks per square yard, we must divide the above figures by 50 to get the cost per square for loading and hauling. Then we have this rule:

To a fixed cost of 3½ cts. per square yard, add 3½ cts. more per square yard for each mile of distance between the car and the point of delivery on the street.

The above cost of hauling is based on team wages of 45 cts. per hour, a speed of 2½ miles per hour, and a 3-ton load.

The paving gang engaged in laying the stone blocks consisted of 3 skilled pavers and a helper, whose principal duty was to deliver sand wherever the sand cushion was not sufficiently thick. Each of the 3 pavers was paid 5 cts. per sq. yd. for laying the blocks. Consequently the work was rapidly done. There were no men engaged in ramming the blocks, but occasionally one of the pavers would

spend a few minutes ramming. Each of the three pavers averaged 70 sq. yds. per day of 10 hours, or 7 sq. yds. per hour, although as much as 85 sq. yds. per paver were laid in one day.

The joints between the blocks were grouted with Portland cement mortar mixed in the proportion of one bag of cement (1 cu. ft.) to one wheelbarrow of sand. The sand was not measured, but probably averaged about 2 cu. ft. to the wheelbarrow. The grout was mixed in a sheet iron tub, shaped somewhat like a long bath-tub, about 18 ins. deep, 30 ins. wide, and 6 ft. long, provided with wooden strips (2 x 6 ins.) bolted to each side of the tub and projecting beyond the ends to serve as handles. The grouting gang was organized as follows:

- 1 man wheeling sand.
- 1 man carrying cement.
- 1 man carrying water.
- 3 men mixing grout with hoes.
- 2 men sweeping grout into joints.

These men averaged a batch of grout (about $2\frac{1}{4}$ cu. ft.) every 3 minutes, and a batch covered about 4 sq. yds. Hence a barrel of cement would cover about 16 sq. yds. With wages at 20 cts. per hour for laborers, the labor cost of grouting was 2 cts. per sq. yd. With sand at \$1.00 per cu. yd. delivered, the cost of sand for grouting was 2 cts. per sq. yd.; and, with cement at \$1.60 per bbl., the cost of cement for grouting was 10 cts. per sq. yd. After the grouting was completed a thin coat of sand was spread over the entire pavement, about 200 sq. yds. being covered by 1 cu. yd. of sand.

Summing up we have:

	Cts. per sq. yd.
Loading and unloading blocks.....	3 $\frac{1}{2}$
Hauling blocks 1 mile.....	3 $\frac{1}{2}$
Laying blocks, pavers, at 35 cts. per hr.....	5
Laying blocks, helper, at 20 cts. per hr.....	1

Total	12 $\frac{1}{2}$

The above does not include the concrete base nor the sand cushion between the base and the stone blocks.

Cost of Stone Block Pavement, Rochester, N. Y.—We have first to consider the dimensions of the blocks. When made of granite, they are split with wedges to tolerably uniform sizes; but when of stratified rock, like Medina sandstone, a carload of blocks will show wide variation in size of individual stone. In depth, of course, the blocks must be quite uniform, and 6 ins. depth is usually specified. In New York City 4 ins. is specified as the maximum

width of granite blocks, and it may be assumed as a certainty that they will not be found less than the maximum allowed, since to split them of less width out of granite would add materially to the cost per square yard. In Rochester, N. Y., $5\frac{1}{2}$ ins. is specified maximum width for Medina blocks but, due to the thin stratification of the stone, they frequently come 3 ins. in width. The maximum length specified is usually 12 ins., the minimum 3 ins. Granite blocks which are quite uniform in size are sold by the 1,000, and sometimes by the square yard, laid. Medina blocks vary so in size that they are sold by the square yard.

Joints are ordinarily about $\frac{1}{2}$ -in. wide, and are filled first with gravel or sand, into which hot tar is poured. In New York City hot gravel is first poured in to the depth of 3 ins. and hot tar poured upon it till voids are filled; then another 2-in. layer of gravel and tar is added, and so on until the joint is full. By this method one-third to half the volume of the joints is tar. In Rochester the Medina sandstone joints are first filled clear to the surface with hot sand (damp sand will not run); then men with pointed wire pins like a surveyor's "stick-pin," used in chaining, force the sand down or pick it out if there is an excess, until the surface of the sand is $1\frac{1}{2}$ to 2 ins. below the surface of the block pavement. Hot tar is then poured in and fills the upper 3 ins. of the joint without penetrating to the bottom. This method gives as good satisfaction, apparently, as the New York method.

In order to economize tar, which is quite an item, I would suggest a combination of the two methods; that is, first fill the joint with sand to within 3 ins. of the surface, then fill the upper 3 ins. with hot pea gravel (screened) and pour in tar.

Cement grout is used as a joint filler in some cities.

With blocks $3\frac{1}{2} \times 12 \times 6$ ins., there are 26 per sq. yd. where joints are $\frac{1}{2}$ -in. and the area of joints is 13% of the total area, and the volume of joint filler is nearly 0.6 cu. ft. per sq. yd. of pavement. If tar is worth 10 cts. a gallon, or 75 cts. a cu. ft., and one-third the volume of the joint is tar, the cost for tar alone will be $0.6 \times \frac{1}{3} \times 75 = 15$ cts. per sq. yd. of pavement, or $1\frac{1}{2}$ gals.

Due to the fact that only one man helped the drivers load their wagons from the car, and only one man helped unload the wagons at the curb, the cost of loading and hauling was so excessive as not to be typical of what can be accomplished under good management, even where extra wagons are not used. Therefore, in the following summary of costs of this Rochester pavement I shall give the same costs for loading and hauling that appear on page 371.

The wagon load in the Rochester work averaged 27 tons.

After the blocks were stacked up at the sides of the street they were laid out on edge in the street in advance of the pavers, and assorted into sizes of uniform thickness, which laborers using wheelbarrows did at a cost of about 3 cts. a sq. yd. Two skilled pavers, with one laborer as a helper to supply stone, formed a gang. A paver laid 5 to 8 sq. yds. an hour; 6 sq. yds. per hr., or

60 sq. yds. per 10-hr. day, may be taken as an average for safe estimating, which, with pavers' wages at 30 cts. an hour and labor at 15 cts., makes cost of laying 6 cts. per sq. yd.

Following the pavers, come a gang of 3 men ramming and raising sunken stone, 1 screening sand for joints, 2 heating sand and tar, 1 wheeling sand for joints, 1 sweeping sand into joints, 7 poking sand down into joints and digging out excess, 5 filling upper 2 ins. of joints with tar, making a gang of 20 men following the pavers, and with wages at 15 cts. an hour, such a gang covering 60 yds. an hour, or 60 sq. yds. per day, makes the cost of ramming and filling joints 6 cts. a sq. yd. Summing up, we have for the total labor cost:

	Per sq. yd.
Loading and unloading.....	\$0.025
Hauling 1 mile.....	0.035
Distributing blocks	0.020
Laying	0.060
Filling joints	0.060
Foreman, at 40 cts. per hr., 30 sq. yds.....	0.012
2 water and errands boys.....	0.007

Total labor

\$0.240

Cost of Medina block pavement:

Per sq. yd.

2½ cu. yd. street excavation.....	\$0.15
6-in. concrete foundation.....	0.50
1-18 cu. yd. sand cushion in place, at \$1.08.....	0.06
Medina block (6-in.) f. o. b. Albion, N. Y.....	1.15
Freight to Rochester.....	0.07
Unloading, hauling and laying.....	0.24
1.5 gals. tar at 10 cts. a gal.....	0.15
1-50 cu. yd. sand for joints.....	0.02

Total

\$2.34

Add for contractor's profit.....

0.26

Total contract price.....

\$2.60

In paving four streets with Medina sandstone blocks, at Rochester, N. Y., the average amount of joint filler was 1.4 gallons of paving pitch per sq. yd.

The foregoing cost data apply to work done over large areas with fairly well organized gangs; but on small areas, such as paving gutters 3 ft. wide, I have had pavers average only 3½ sq. yds. per hour per paver, each paver securing his own blocks from piles along the curb.

By comparison with the cost of similar work done at St. Paul, described previously, it will be seen that this Rochester work was not as economically done. It should be noted, however, that in St. Paul a cement grout filler was used, while in Rochester the joint filler was tar.

Cost of Stone Block Pavement, Baltimore, Md.*—In 1908 there were 1,517 sq. yds. of Medina sandstone blocks laid by day labor forces for the city, replacing old wood blocks.

Wood blocks were removed from the tracks on Fayette St. from

*Engineering-Contracting, Aug. 18, 1909.

Calvert to Charles streets, and also on Calvert street from Baltimore to Lexington street, and were replaced with Medina sandstone. The joints of the pavement were poured with Warren's Puritan brand block filler and followed with a covering of hot gravel. The itemized cost of the work was as follows:

	Per sq. yd.
Blocks	\$2.350
0.0325 cu. yd. stone dust, at \$1.20.....	0.039
0.02 cu. yd. screened gravel, at \$1.20.....	0.024
41.9 lbs. filler, at \$1 per cwt.....	0.419
1.3 lbs. coal, at \$4 ton.....	0.003
Hauling	0.094
Labor	0.354
Total (1,517 sq. yds.).....	\$3.297

This high cost is characteristic of all the work done by the city forces in Baltimore.

Cost of Granite Block Pavement, New York.—Mr. G. W. Tillson, in "Street Pavements and Paving Materials," p. 204, gives the following data on the cost of granite block pavement in New York City in 1899. The day was 10 hrs. long:

Concrete gang:	Per day.
1 foreman	\$ 2.00
8 mixers on two boards, at \$1.25	10.00
4 wheeling stone and sand, at \$1.25.....	5.00
1 carrying cement and supplying water, at \$1.25....	1.25
1 ramming, at \$1.25.....	1.25

Total, 240 sq. yds. (40 cu. yds.), at 8.6 cts. \$20.50

The concrete is shoveled direct from the mixing boards to place.

Cost 1 : 2 : 4 concrete:	Per cu. yd.
1½ bbls. natural cement, at \$0.90.....	\$1.20
0.95 cu. yd. stone, at \$1.25.....	1.19
0.37 cu. yd. sand, at \$1.00.....	0.37
Labor	0.51

Total **\$3.27**

With concrete 6 ins. thick this is equivalent to 54.6 cts. per sq. yd. for the concrete foundation.

The granite blocks were laid two days later with the following gang:

	Per day.
10 pavers, at \$4.50.....	\$ 45.00
6 rammers, at \$3.50	17.50
6 chackers, at \$1.50.....	9.00
20 laborers, at \$1.25	25.00
2 foremen, at \$3.50	7.00

Total, 650 sq. yds., at 16 cts. \$103.50

This is equivalent to 65 sq. yds. per paver per day.

	Per sq. yd.
Labor laying blocks, as above given.....	\$0.16
21½ granite blocks, at \$55 per M.....	1.24
3½ gals. paving pitch, at 7 cts.....	0.24
1½ cu. ft. gravel for joints, at \$1.95 per cu. yd....	0.10
1½ cu. ft. sand for cushion, at \$1.00 per cu. yd....	0.06
1 sq. yd. concrete, as above given.....	0.55

Total **\$2.35**

A gang laying granite block pavement on a 7-in. bed of sand was as follows:

	Per day.
4 pavers, at \$4.50	\$18.00
2 rammers, at \$3.50	7.00
3 chuckers, at \$1.50	4.50
3 laborers, at \$1.25	3.75

Total, 280 sq. yds., at 12 cts. \$33.25

This is equivalent to 70 sq. yds. per paver per day.

	Per sq. yd.
Labor	\$0.12
24 granite blocks, at \$55 per M, delivered	1.32
0.2 cu. yd. sand, at \$1	0.20

Total

Apparently the labor cost of melting and pouring the pitch filler is included in work done by the 20 laborers.

Cost of Laying Granite Block Pavement, New York.*—The work was done in 1905 at 96th street. The paving was done by contract and was commenced Oct. 23, and finished Dec. 20 of the same year. The work consisted of laying 5,167 sq. yds. of granite block pavement on a 6-in. concrete base. The blocks used were 12 in. x 3½ in. x 7 in., and 116,250 of them were laid. The total number of lineal feet of joints that had to be tarred was 161,975.

In unloading and piling stone on the sidewalks the material was handled by the laborers by hand, the distance over which the stone was carried being but a few feet. It was found that each laborer unloaded and piled 1,390 blocks, or 62 sq. yds., per day.

The following was the labor cost, it being estimated that 22.5 blocks make 1 sq. yd.:

<i>Unloading and Piling Blocks:</i>	Per sq. yd.
0.014 day labor, at \$1.75	\$0.023
0.0006 day foreman, at \$3.50	0.002

Total

<i>Excavating Old Pavement and 6 Ins. Earth:</i>	
0.077 day labor, at \$1.75	\$0.135
0.0054 day foreman, at \$3.50	0.019

Total

<i>Mixing and Laying Concrete Base:</i>	
0.128 day labor, at 1.75	\$0.225
0.008 day foreman, at \$3.50	0.028

Total

<i>Paving and Tarring Joints:</i>	
0.021 days pavers, at \$4.00	\$0.084
0.0175 days pavers' helper, at \$2.00	0.035
0.0042 days rammers, at \$4.00	0.025
0.0017 days spreading sand cushion, at \$1.75	0.003
0.013 days filling joints with gravel, at \$1.75	0.023
0.004 days pouring tar into joints, at \$1.75	0.007
0.007 days tending tar and gravel kettles, at \$1.75	0.012
0.002 days foreman, at \$5.50	0.011

Total

*Engineering-Contracting, June 20, 1906.

It will be noted none of this work was done economically. The labor on the concrete, for example, was double what is commonly required under good management.

Each paver laid only 1,066 blocks, or $47\frac{1}{2}$ sq. yds. per day, which is an equally miserable showing.

Cost of Granite Block Pavement, Baltimore, Md.*—This work involved laying 12,500 sq. yds. of granite block pavement on Light St., Baltimore, during Aug. 8 to Dec. 8, 1908. The work was not done by contract, but by city forces working by the day. The excessively high cost of the labor per sq. yd. adds another example to the invariable rule that it is cheaper to do such work by contract.

It is stated that during the 4 mos. one week was lost on account of bad weather and three weeks on account of the failure of the blocks to arrive on time. During a large part of the time, two 8-hr. shifts were worked daily. The Belgian blocks were quarried in Maine and shipped to Baltimore by boat, the first boat arriving Aug. 24. There were $24\frac{1}{2}$ blocks per sq. yd., the price being \$68.50 per M delivered on the line of the work.

The cost of the 6-in. concrete base was as follows, the mixture being $1:3\frac{1}{2}:6\frac{1}{2}$:

	Per cu. yd.	Per sq. yd.
Gravel, 1 cu. yd.....	\$1.10	\$0.183
Sand, $\frac{1}{2}$ cu. yd., at \$0.72.....	0.36	.060
Cement, 4 bags	1.286	0.214
Total materials.....	\$2.746	\$0.457
Labor	0.786	0.131
Grand total	\$2.531	\$0.588

It is stated that an engineman, at \$2.50 per 8 hrs., and 13 laborers, at \$1.67, operated a $\frac{1}{4}$ cu. yd. mixer (part of the time using a Ransome and part of the time using a Smith mixer), and the average 8 hrs. run was 333 sq. yds., or 56 cu. yds.; but the exceedingly high cost of \$0.786 per cu. yd. for labor could not have occurred had the output averaged even the 56 cu. yds.

The average organization of the paving gang and the wages paid were as follows:

	Per 8 hrs.
1 foreman, at \$4.00.....	\$ 4.00
6 pavers, at \$4.00.....	24 00
2 rammers, at \$3.00.....	6 00
4 carts (including horse, cart and driver), at \$2.50.....	10 00
7 pourers, at \$1.75.....	12 25
16 laborers, at \$1.66 $\frac{2}{3}$	26 62
2 stone cutters, at \$4.00.....	8 00
Total	\$90.87

Special efforts were made to keep this gang constantly employed, and absolutely no time was lost by it other than delays

**Engineering-Contracting*, Sept. 22, 1909.

occasioned by bad weather and failure of blocks to arrive on time. The concrete base at all times was kept well in advance of the pavers, experience having shown that the laborers would do better and quicker work when they could see an abundance of it ahead and no interruption. The average day's work complete for this gang was 267 sq. yds. or $44\frac{1}{2}$ sq. yds. to the paver. This makes the cost 34 cts. per sq. yd., and does not include hauling the blocks from the boat to the street. This 34 cts. per sq. yd. is just about three times what it would cost a competent contractor, as will be seen by comparison with records above given.

It should be noted that the joints were filled with gravel and pitch, and that the labor of the 7 "pourers," being \$12.25 per day, as above given, amounted to 4.6 cts. per sq. yd. It is stated, however, that the total labor cost of pouring was 5.75 cts. per sq. yd., from which it would appear that about 2 laborers (of the 16) were used to open barrels and keep the fires going, etc.

Coal, at \$4 per ton, was used to melt the pitch and heat the gravel, and this wood cost $\frac{1}{4}$ ct. per sq. yd. of pavement. The tar kettle had a capacity of 2 tons, and was mounted on wheels. The gravel heater, also on wheels, had a capacity of 32 cu. ft. of gravel, but did not meet the requirements, so that two unmounted sheet iron pans ($3\frac{1}{2} \times 7$ ft.) were also used. It is stated that prior to the use of this tar kettle and the gravel heater, fuel (wood, at \$5 per cord) had cost $1\frac{1}{2}$ ct. per sq. yd.

Summarizing the cost, we have:

Materials:	Per sq. yd.
24 $\frac{1}{2}$ granite blocks delivered on street, at \$48 per M.....	\$1.5900
0.063 cu. yds. stone dust for cushion (instead of sand), at \$1.05	0.0675
0.039 cu. yds. gravel for joints, at \$1.80.....	0.0700
48 lbs. tar for joints, at \$0.01.....	0.4800
1 $\frac{1}{4}$ lbs. coal for heating tar and gravel, at \$4.00 per ton....	0.0025
Total materials	\$2.3300
Labor:	
Heating and pouring filler and gravel.....	\$0.0575
Other labor laying blocks.....	0.2675
Total	\$2.6550
Concrete base (6-in.) as above given.....	0.5880
Grand total	\$3.2430

This does not include removing an old pavement and grading.

The very high cost of the tar filler per sq. yd. is noteworthy. If it weighed 10 lbs. per gal., then there were 4.8 gals. per sq. yd., an altogether unnecessary amount.

After the final pouring of the tar (Warren's Puritan filler), the pavement was covered with hot gravel.

Cost of Dressing Old Granite Blocks, Baltimore, Md.*—Before lay-

**Engineering-Contracting*, Sept. 22, 1909.

ing a new granite pavement on Light St., Baltimore, 6,500 sq. yds. of old granite blocks were taken up and relaid by city forces. The cost of laying the new blocks is given on page 377.

The following costs relate only to the dressing of the old blocks and relaying them. The costs were exceedingly high, due to the fact that the work was done by city forces.

Each man dressing old granite blocks averaged 253 blocks per 8-hr. day, and the cost was \$13.16 per M, which indicates that the stonecutters received less than \$3.30 per day. When relaid the labor cost was as follows:

	Per sq. yd.
Dressing and laying old blocks.....	\$0.4325
Heating and pouring filler and gravel.....	0.0575
Total labor	\$0.4900

For rates of wages and organization of the gang engaged in laying, see page 377.

Cost of Taking Up and Relaying a Cobble Stone Pavement.*—In repairing pavements, the costs of labor vary greatly, owing to the fact that the repair work is done in small patches and there is much time lost in the moving of tools from place to place as well as the time the men consume in moving. Records of these costs are exceedingly difficult to obtain, but we are fortunate in being able to give the cost of doing a repairing job that involved enough work to keep a repair gang busy for a day, so that some idea of the cost of the various labor items can be calculated.

The wages paid were as follows for an 8-hr. day:

Foreman	\$4.50
Laborers	1.86
Pavers	6.30
Rammers	3.30
2-horse wagon and driver.....	6.00
Cart and driver	3.50

The work consisted of cobble stone paving, between the curb and a street car track, being 10 ft. wide and 104 ft. long. A 10-in. gutter of flag stones was laid 15 ins. from the curb; the intervening 15 ins. being laid with cobbles. In all there were 115.55 sq. yds. of paving, 9.55 sq. yds. of this being in the gutter, and 14.55 sq. yds. being between the gutter and the curb.

The system of carrying on the work was for three laborers to loosen the cobbles with bars, being followed by three laborers with picks, who piled the stones within reach of the pavers and kept the ground beneath the paving loosened with their picks. A wagon hauled ashes from the city stock pile to be used beneath the new paving, and it also hauled some cobbles from the yard that were needed. One laborer spread the ashes for the pavers.

One paver set the gutter and paved between the curb and the gutter. The curbing was not disturbed. This paver laid 24 sq. yds.

**Engineering-Contracting*, Oct. 2, 1907.

in the day, more than one-third of it being gutter. The other three pavers did the rest of the laying, doing not quite 31 sq. yds. apiece. Two rammers rammed 106 sq. yds. of paving, being the entire amount less the gutter. The man who spread the ashes followed the rammers spreading sand over the work. The cart hauled the sand. At the close of the day the 7 laborers cleaned up in a few minutes.

The various labor items cost as follows:

Tearing up and handling stone:

2 laborers with bars.....	\$4.98	
2 laborers with picks	4.98	\$ 9.96

Paving:

1 laborer on ashes and sand.....	\$ 1.66	
4 pavers	21.20	
2 rammers	7.80	\$0.66

Hauling materials:

Cart sand	\$2.50	
Wagon for ashes and stone.....	5.00	8.50

Superintendence		4.50
-----------------------	--	------

Grand total		\$52.62
-------------------	--	---------

The cost per sq. yd. was:

Tearing up and handling stone.....	\$0.686
Paving206
Superintendence040
Hauling materials073

Total cost per sq. yd.....	\$0.464
----------------------------	---------

The cobble stones averaged about 8 ins. deep, hence the cost of tearing them up and stacking them was nearly 40 cts. per cu. yd.

Cost of Laying Asphalt Block Pavement, New York.*—In the upper part of New York City asphalt block pavements have been in use for many years and have steadily grown in popularity, particularly for residence streets. Formerly it was the custom to lay the blocks on edge, following the precedent of stone block and brick pavement construction; but within recent years the asphalt blocks have been laid flatwise, thus forming a wearing coat of asphalt blocks 3 ins. thick, each block being 3 x 5 x 12 ins. The old theory that a block pavement of any kind should be made of blocks set on edge is thus utterly overthrown, and it is not unreasonable to expect to see the time when paving bricks will also be laid flatwise, thus effecting a great economy in material. About five years ago the managing editor of this journal wrote an article setting forth the reasons why paving bricks of larger size, known as "blocks," should be laid flatwise instead of edgewise, but conservatism among city engineers is so strong that, so far as we know, not a single city has adopted the plan of laying paving brick flatwise.

Coming now to the method of laying asphalt blocks in New York City, we find another departure from precedent in that the venerable "sand cushion" has been abandoned. Of course a base of

**Engineering-Contracting*, Sept. 26, 1906.

concrete is provided in the usual manner, but, instead of laying a sand cushion on this base, it is now the practice to spread a thin coat of cement mortar on which the asphalt blocks are laid. This mortar coat is $\frac{1}{2}$ in. thick, made of 1 part cement to 4 parts sand. It is mixed dry and wheeled onto the concrete in barrows, roughly spread with shovels and rakes and then leveled off with a wooden straight edge. To insure perfect leveling and the desired thickness of mortar, strips of wood $\frac{1}{2}$ in. thick are laid at intervals of about 10 ft. Then two men shove a straight edge over these strips until the dry mortar is spread evenly. After this a man with a hose sprinkles the mortar until it is quite damp and ready to receive the asphalt blocks.

No attempt is made to bed the asphalt blocks down into the mortar, but they are merely laid firmly and given a rap with a hammer. In order to keep the courses of blocks in perfect line, a man with an ax follows the pavers and shoves over any parts of courses that are crooked by prying the blocks along with the ax blade shoved into the joint.

The blocks are loaded in wagons from boats or cars, hauled to the site of the work in advance of the concreting, and stacked in piles on the sidewalk along the curb. Asphalt blocks are not as tough as stone or brick and must be handled more carefully. In loading, as well as in unloading, one man tosses blocks to another man who stacks them up in the wagon, or on the sidewalk. About 300 blocks make a wagon load, and as each block weighs 18 lbs., a load is approximately 2.7 tons. In loading the blocks from gondola cars into wagons, it takes two men in the car to deliver blocks to one man in the wagon, who piles them up. With four men in the car and two men on the wagon (including the driver as one of these two men), 300 blocks are easily loaded in 10 minutes, even when the men in the car have to walk several steps to get each block. But when the blocks are merely picked up and tossed to the men in the wagon, these six men will load 300 blocks in $7\frac{1}{2}$ mins. If the teams are in sufficient number for one team to arrive at the car every 10 mins., the 5 men (and the driver) load 1,800 blocks per hour. With wages of laborers at 20 cts. an hour, and team with driver at 45 cts., the cost of loading (including lost team time) is 80 cts. per 1,000 blocks, or 1.7 cts. per sq. yd.

Then the hauling costs \$1.20 per 1,000 blocks per mile of haul from car to place of unloading, when 300 blocks form a load, speed of travel being $2\frac{1}{2}$ miles an hour.

In unloading the wagon the driver and another man in the wagon toss blocks to two men on the sidewalk, who pile them up. These men unload 300 blocks in $7\frac{1}{2}$ mins. without difficulty, but allowing 10 mins. for unloading, so as to include waits for wagons; we have a cost of 60 cts. for unloading each 1,000 blocks including the lost time of the team. Hence, to estimate the cost of handling and hauling, with wages as above given, use the following rule:

To a fixed cost of \$1.40 per M for loading and unloading (including lost team time), add \$1.20 per M for each mile of haul.

The organization of the gang laying the pavement (exclusive of the gang laying the concrete base), is as follows:

	Per hour.
4 pavers laying blocks, at 40 cts.....	\$ 1.60
16 men carrying blocks, at 20 cts.....	3.20
1 man lining up blocks, at 20 cts.....	.20
2 men splitting blocks, at 20 cts.....	.60
1 man laying strips for straight edge, at 20 cts....	.30
7 men mixing mortar, at 20 cts.....	1.40
6 men wheeling and spreading mortar, at 20 cts....	1.20
2 men raking mortar, at 20 cts.....	.40
2 men leveling mortar with straight edge, at 20 cts..	.40
1 man sweeping sand into joints, at 20 cts.....	.20
1 foreman, at 50 cts.....	.50
42 men, total, 160 sq. yds., at 6¼ cts.....	\$10.00

This is equivalent to 40 blocks per paver per hr., or 360 per day.

This gang worked 9 hrs. daily, and when engaged in laying blocks averaged 180 to 200 sq. yds. per hr. There was no loading on the part of the men who carried the blocks to the pavers, nor on the part of the pavers. But the 17 men mixing, wheeling and spreading mortar averaged only 23 cu. yds. of mortar placed per day, which is not a very good record.

The asphalt blocks were carried, two at a time, by hand, and were not delivered in wheelbarrows. They were laid to break joint by 4 ins., and this left a good deal of work to be done at the curbs in cutting at least two blocks to fill out each course. The two men splitting blocks for this purpose were unable to keep up with the paving gang. Hence, at intervals, the whole gang stopped paving and went back to assist in splitting blocks to close the courses, and to fill the joints of the blocks with sand.

No cement is mixed with this sand filler, but loads of dry sand are hauled onto the pavement, dumped, spread, and swept into the joints. A cubic yard of sand fills the joints of about 200 sq. yds. of block pavement.

The time required to spread the sand filler and fill out the courses, when included with the time actually spent in laying reduced the average output to 160 sq. yds. per hour, making a cost of 6¼ cts. per sq. yd. for laying the mortar and blocks and filling the joints with sand. Wages actually paid were somewhat lower than those above given, being \$1.50 for 9 hours for laborers and \$2.50 to \$2.00 for pavers. The pavers did not belong to a union.

It will be noted that each of the 4 pavers averaged 45 sq. yds. per hour when not engaged in cutting and fitting blocks at the end of courses, and, as a matter of fact, on the best day each paver averaged 55 sq. yds. per hour, or 495 sq. yds. per day.

To the contractor who has been used to laying stone block pavement only, these records may seem erroneous. Even the brick paving contractor may be inclined to doubt their accuracy. It should be remembered, however, that one asphalt block covers 5 x 12, or 60 sq. ins. of surface, and that it takes only 21 asphalt blocks per square yard, as compared with two or three times that number of paving bricks or blocks.

The time consumed in selecting stone blocks and in bedding them in the sand cushion materially reduces the output of the pavers compared with asphalt block work.

Cost of Asphalt Block Pavement, Baltimore.*—This work was done in 1908 by city day labor forces, and, as is usual in such cases, the cost was high. An 8-hr. day was worked, wages being as given on page 377.

Nearly 20,000 sq. yds. were laid in 1908, some of it on a concrete base, of which the following is a typical cost where the concrete was 6 in. thick, the stone dust cushion being 1 in. thick, and the asphalt block wearing coat being 3 in. thick. The blocks were 3 x 5 x 12 in.

	Per sq. yd.
1-6 cu. yd. concrete base, at \$3.60.....	\$0.600
0.07 cu. yd. stone dust, at \$1.20.....	0.084
20.7 asphalt blocks, at \$65 per M.....	1.340
Labor laying blocks	0.220
Total	\$2.244

Cost of Creosoted Wood Block Pavement, Minneapolis.*—Minneapolis was among the first cities in the United States to lay creosoted wood block pavement to any extent. At the end of 1902 the city had over 200,000 sq. yds. of this type of pavement, and since then this yardage has been largely increased. Minneapolis was also probably the first city to use blocks made of Norway pine and tamarack to any considerable amount.

The following figures show the actual average detailed cost of about 145,000 sq. yds. of pavement constructed in various parts of Minneapolis in 1908. The figures were obtained from pay rolls, bills of materials and estimates and are the actual cost for labor and materials for constructing the pavement.

The average unit cost per square yard for the 145,000 sq. yds. of creosoted wood block pavement was as follows:

	Per sq. yd.
Removing old cedar paving.....	\$0.0270
Grading	0.1320
Concrete base (labor and materials).....	0.5226
Cushion sand, at \$0.80 per cu. yd.....	0.0200
Creosoted paving blocks (f. o. b. Mpls.).....	1.3900
Hauling blocks	0.0450
Laying blocks	0.0590
Hauling cement	0.0090
Paving pitch filler, at 5.7 cts. per gal.....	0.0570
Hauling pitch for filler.....	0.0100
Labor on filler	0.0120
Asphalt filler along St. R. R. tracks.....	0.0029
Headers (plant)	0.0030
Sand on finished paving.....	0.0100
Tools	0.0200
Rolling	0.0100
Cleaning up finished street.....	0.0050
Miscellaneous materials	0.0030
Miscellaneous labor	0.0100
Total	\$2.3475

*Engineering-Contracting, Aug. 18, 1909.

Summarizing the labor items of laying the wood block pavement, we have:

	Per sq. yd.
Laying blocks	\$0.0530
Labor on pitch filler	0.0120
Rolling	0.0100
Cleaning up	0.0050
Total	\$0.0800
Hauling blocks	0.0450
Miscellaneous labor	0.0100
Grand total	\$0.1410

This does not include labor of removing old pavement and grading.

The organization and wages of the gang directly engaged in laying the blocks were about as follows:

	Per day.
6 pavers, at \$2.50	\$15.00
6 helpers setting up blocks, at \$2	12.00
7 wheelers, at \$2	14.00
4 sand cushion men and sweepers, at \$2	8.00
2 sand cushion men and sweepers, at \$2.25	4.50
2 sand cushion men and sweepers, at \$2.50	5.00
1 grader, at \$2.25	2.25
1 water boy, at \$1.20	1.20
Total (1,050 sq. yds.)	\$61.95

This gang averaged about 1,050 sq. yds. per 8-hr. day for the full season's work. This included waits for material at times and delays for other causes. Some days the gang laid as high as 1,400 sq. yds.

The detailed cost of the concrete base was as follows:

	Per sq. yd.
Crushed limestone, at \$1.65 per cu. yd.	\$0.2186
Sand, at \$0.60 per cu. yd.	0.0374
Cement, at \$1.12 per bbl.	0.1122
Labor	0.1303
Street railway concrete	0.0241
Total	\$0.5226

The above figures include, of course, a number of items peculiar to the city, which might not obtain in another community. For instance, the first item—removing old blocks (cedar) happens only in a few streets, but yet amounts in total to enough materially to affect the cost price and must be considered. Also in the detailed cost of the concrete, there is included an item for street railway concrete. This item would not appear elsewhere, but is a very considerable one in Minneapolis. The street railway company maintains paving from the outer edge of the rails in one track to the outer edge of the rail in the other track, and does not include the ties extending beyond the rail, 1½ ft. in each case, and for convenience to them and to the city, the railway company puts in the concrete base from the rail to end of the tie at the same time it puts

in the concrete for the tracks, the city paying the company for it. This constitutes the item of "street railway concrete." An item of "headers" also is included. This is a 4 x 10-in. plank set on edge at the returns on unpaved streets to protect the edge of the new paving.

The cost varies in different localities in the city, there being as much as 25 cts. per square yard difference. This is due to difference in length of hauls for materials, difference in the grading and from other local conditions.

The concrete is mixed by hand. It is 5 ins. thick and is mixed in the proportion of 1:3:7. The stone used in 1908 was a crushed limestone, costing on an average \$1.65 per cu. yd., on the basis of \$1 per cu. yd. at the crusher, the city doing the hauling. The cement cost \$1.12 per barrel f. o. b. Minneapolis, and the mason sand for concrete cost on an average 60 cts. per cu. yd.

The filler used in the work was distilled from coal tar and was furnished by the Barrett Manufacturing Co. It was brought on the streets in hot tanks. The season's work averaged about 10 lbs. of pitch filler to the square yard of finished pavement. This is a little less than one gallon to the yard.

The sand cushion was 1 in. thick and the fine sand used cost on an average 60 cts. per cu. yd.

The blocks used were Norway pine and tamarack, 4 ins. thick, and were treated with 16 lbs. of oil to the cubic foot.

Common labor was paid at the rate of \$2 per day, teams were paid \$4 per day, block layers \$2.50 per day, and a few special men from \$2.25 to \$2.50 per day. An 8-hr. day was worked.

All the work was done by force account under the direction of B. H. Durham, street engineer, to whom we are indebted for the above information.

Labor Cost of Creosoted Wood Block Pavement at Seattle.*—The following data abstracted from the "Pacific Builder and Engineer" show the labor cost of constructing some creosoted wood block pavement on 4th Ave. in Seattle. The blocks had a cross-section of 3 x 4 x 8 ins. and were made from selected Western Washington fir stock. They were treated by the Pacific Creosoting Co. at its Eagle Harbor works. The sub-base for the pavement consisted of 6 ins. of concrete, on which was placed a 1-in. cushion of cement and sand mixed 1:3, spread and sprinkled.

During one day's work 322 sq. yds. of the pavement were laid, the organization of the gang and wages being as follows:

	Per day.
16 laborers, at \$2 per day.....	\$32.00
1 paver, at \$5 per day.....	5.00
Superintendent, at \$5 per day.....	5.00
Total, 322 sq. yds., at \$0.1302.....	\$42.00

*Engineering-Contracting, Aug. 4, 1909.

This gang mixed the grout, spread it and laid the blocks at the following cost:

	Per sq. yd.
Laborers	\$0.0993
Pavers	0.0155
Superintendent	0.0155
Total	\$0.1303

The concrete base cost 90 cts. per sq. yd. by contract. Sand cost \$1.25 per cu. yd. delivered, and cement was \$2.25 per bbl. delivered. About 4,000 sq. yds. of pavement was constructed.

It should be noted that there was an unnecessarily large number of laborers (16) to one paver.

Cost of Cresseded Wood Block Pavement, Holyoke, Mass.*—The following work was done in 1906, by day labor, under the supervision of Mr. James L. Tighe, city engineer. About 5,500 sq. yds. of wood blocks were laid on a 5-in. concrete base, the concrete being a 1:3:6 mixture. The 1-in. cushion coat was a 1:7 mixture. An 8-hr. day was worked. The organization of the gang for excavating, concreting and paving with blocks was as follows:

Excavation:	Per day.
1 steam roller and engineman hauling plow.....	\$ 10.00
4 men on plow, at \$2.00.....	8.00
20 men loading earth, at \$2.00.....	40.00
4 teams hauling ($\frac{1}{2}$ mi.), at \$4.00.....	16.00
2 men finishing subgrade, at \$2.00.....	4.00
Total excavation	\$ 78.00
Hauling Stone and Sand:	
6 men loading stone from cars, at \$2.00.....	\$ 12.00
2 teams hauling stone, at \$4.00.....	8.00
2 men loading sand in pit, at \$2.00.....	4.00
2 teams hauling sand (0.8 mi.), at \$4.00.....	8.00
Total hauling broken stone and sand.....	\$ 32.00
Mixing Concrete:	
20 men mixing and placing by hand, at \$2.00.....	\$ 40.00
Paving:	
4 men mixing and placing cement cushion, at \$2.00..	\$ 8.00
2 pavers laying blocks, at \$2.00.....	4.00
6 pavers' tenders, at \$2.00.....	12.00
1 man spreading sand over pavement, at \$2.00....	2.00
Total paving	\$ 26.00
Supervision:	
2 foremen, at \$3.10.....	\$ 6.20
1 superintendent	5.00
Total supervision	\$ 11.20
Grand total labor	\$189.20

*Engineering-Contracting, May 13, 1906.

This gang excavated earth and laid 300 sq. yds. per 8-hr. day, hence the labor cost was:

	Per sq. yd.
Excavation	\$0.260
Hauling broken stone and sand.....	0.113
Mixing and placing 5-in. concrete.....	0.133
Paving	0.087
Supervision	0.037
Total	\$0.630

The cost of the concrete materials was about as follows:

	Per sq. yd.
0.14 cu. yd. broken stone for concrete, at \$1.20.....	\$0.17
0.07 cu. yd. sand (pit royalty), at \$0.10.....	0.01
0.14 bbl. cement for concrete, at \$1.67.....	0.24
Total materials for concrete.....	\$0.42

We have the following cost:

<i>Materials for Wearing Coat:</i>	Per sq. yd.
54 creosoted blocks, at \$3.95.....	\$2.140
0.03 bbl. cement for mortar cushion, at \$1.67.....	0.050
0.03 cu. yds. sand for mortar cushion, at \$0.55.....	0.017
Total materials for wearing coat.....	\$2.207

<i>Labor on Wearing Coat:</i>	
Men on cement cushion.....	\$0.027
Pavers laying wood blocks.....	0.013
Pavers' tenders	0.040
Man spreading sand over blocks.....	0.007
Supervision, 4% of labor.....	0.006

Total labor on wearing coat.....\$0.092

<i>Concrete Base:</i>	
Materials for 5-in. concrete base.....	\$0.420
Labor on concrete base, incl. 6% for supervision.....	\$0.140
Total, excluding grading	\$2.859
Grading, incl. 6% for supervision.....	0.276

Grand total**\$3.135**

Life of Wood Block Pavement.*—Mr. William Weaver gives the following English data:

Wood paving has received my special attention since 1872, when it came into extended use.

In Kensington, May, 1882, I had laid experimental areas of creosoted wood blocks, respectively 3 ins., 4 ins. and 5 ins. deep, jointed in different ways, and as the result of careful observation, I advised my board to lay 4-in. creosoted deal blocks in Sydney place, an omnibus route leading from Fulham road to South Kensington station. These blocks were laid close, and grouted first with pitch and then with Portland cement, the work being carried out in November, 1889, and the blocks lasted until June, 1901, when the road was repaved in a similar manner.

The conclusion at which I have arrived, after my experiments initiated in 1882, was that creosoted deal furnished the most

**Engineering-Contracting*, Sept. 15, 1909.

suitable and economical road pavement; further, that 5-in. blocks lasted as long as 6-in., and that 4-in. creosoted blocks answered all the requirements of roads where the traffic is not excessive. In order to understand that a 5-in. will last as long as 6-in. paving, it must be borne in mind that wood paving must be renewed as soon as its general surface ceases to drain itself; and this happens when the blocks forming the haunches of the road are reduced between 1 in. and 2 ins. in depth, the channel or watercourse meanwhile not being exposed to similar traffic, suffer no diminution of depth.

The above conclusions are fully borne out by Table XIV of instances, extracted from my annual reports, which furnishes details of 304,220 yds. of 5-in. and 137,164 yds. of 4-in. wood paving laid in Kensington since 1887.

In connection with that list, an instructive comparison is furnished by the history of the wood laid in the Hammersmith road in continuation westward of the area laid in Kensington; at the same time (May, 1886), Hammersmith laid down 6-in. plain deal blocks which lasted a little over six years, being replaced in July, 1892, with 5-in. jarrah blocks. After eight years the jarrah blocks were reversed and rebudded in July, 1900, and replaced with 5-in. creosoted deal in July, 1903. The 5-in. creosoted deal adjoining in Kensington, laid in May, 1886, lasted until September, 1901, equal to the combined lives (less two years) of the plain deal with jarrah together.

Further, with regard to the above schedule, I may add that all the roads enumerated are omnibus routes, but the traffic on each, of course, varies in severity.

In conclusion, I would point out that by reducing the depth of the wood (each inch of reduction means over a shilling per yard saved), and, further, by about doubling the life of the wood by creosoting, wood paving need no longer be considered an expensive luxury, but must be regarded as a sanitary and economical substitute for macadam, where costing over 8d. per yard annually to maintain. At the same time it must not be lost sight of that such substitution has a tendency to increase the rateable value of the abutting property, owing to the improved appearance, cleanliness and quietude of the road.

Cost of Asphalt Pavement in California.*—Through the kindness of Mr. Charles Kirby Fox, C. E., we are enabled to give the costs of two asphalt paving jobs in a Southern California city.

The first piece of work was done under a Vrooman act contract, the contract price being \$1.89 per sq. yd. It consisted of the construction of pavement on two blocks of street. The street was 48 ft. wide, had 2½ ft. concrete gutters, a rise of 6 ins. to 8 ins. and a grade of 1 per cent. It drained well and there were no water holes. The pavement consisted of a 5-in., 1:3:6 concrete base, a 1-in. binder course and a 2-in. asphalt wearing surface.

**Engineering-Contracting*, April 1, 1908.

TABLE XIV.

Name of road.	Sq. yds.	Description of wood.	Date when laid.	Life of wood years.
Westbourne grove and Archer street...	10,328	5-in. creosoted deal	Dec., 1887	20
		5-in. naphthalized blocks*	Dec., 1887	10.42
		5-in. plain deal*	Dec., 1887	6
		5-in. blocks dipped in creosote*	Dec., 1887	10.42
Kensington High street.....	1,714	4-in. jarrah	Oct., 1893	6.92
		4-in. creosoted deal	Sept., 1899	.7
		4-in. red gum (American)*	Sept., 1899	3
Kensington road, between Honton street and Russell road.....	16,550	5-in. creosoted deal	Mar., 1890	11.6
Kensington road, from Russell road to western boundary	1,528	5-in. creosoted deal	May, 1886	15.2
Brompton road	12,183	5-in. creosoted deal	Sept., 1893	10.08
Old Brompton road.....	25,307	5-in. creosoted deal	Oct., 1891	12
	2,509	4-in. jarrah	Oct., 1891	3
Pembroke Villas	6,543	5-in. creosoted deal	May, 1896	Still down
		5-in. jarrah*	May, 1896	8.16
		5-in. karri*	May, 1896	8.16
		6-in. red gum (Australian)*	May, 1896	9.60†
		6-in. Jodolized deal*	May, 1895	9.60†
Holland Park avenue.....	18,846	5-in. creosoted deal	Oct., 1893	14
Sydney place	2,509	4-in. creosoted deal	Nov., 1889	11.60
Cromwell road	16,504	4-in. creosoted deal	Oct., 1900	Still down
Holland road	16,160	4-in. creosoted deal	June, 1899	Still down

* Trial sections under equal conditions of traffic. † Extensively patched in 1902.

Grading.—The grading cost \$0.1223 per sq. yd. and was done by the following organization:

	Per day.
1 foreman, at \$5.....	\$ 5.00
1 timekeeper, at \$3.....	3.00
1 engineman, at \$3, part time on steam roller and part time on plowing.....	3.00
2 teams plowing, at \$4.....	12.00
6 teams hauling, at \$4.....	24.00
14 laborers shoveling, at \$2.....	28.00
Total, 610 sq. yds.....	\$75.00

Concrete Base.—The 5-in. concrete base was made of a 1:3:6 mixture. On Job No. 2 it was found, however, that these proportions did not work well, as all the voids were not filled, and that a 1:3:5 or 1:4:6 mixture made a better concrete. The concrete was hand mixed on two 7 x 7-ft. boards, in the following manner: First, the sand and cement were dumped on the board and hoed across and wet; then the stone was dumped on the mortar and the whole mess pulled back and forth across the boards and set on the ground in about the place it was to occupy. In the meantime the other board was being filled up and the operation repeated, the first board being pulled a little forward and refilled. The concrete secured was fair. The cost of mixing and placing the concrete was as follows:

	Per cu. yd.	Per sq. yd.
0.93 bbl. cement, at \$2.50.....	\$2.28	\$0.316
0.45 cu. yd. sand, at \$0.80.....	0.31	0.043
0.9 cu. yd. stone, at \$2.00.....	1.80	0.250
Tools and water.....	0.13	0.016
Labor and superintendence.....	1.20	0.166
Total	\$5.72	\$0.791

The wages and organization of the gang engaged in mixing and placing the concrete base were as follows:

	Per day.
1 superintendent, at \$5.....	\$ 5.00
1 timekeeper, at \$3.....	3.00
2 laborers, at \$2, wheeling sand.....	4.00
3 laborers, at \$2, wheeling stone.....	6.00
6 laborers, at \$2, mixing.....	12.00
1 laborer, at \$2, tending water.....	2.00
2 laborers, at \$2, leveling and spreading.....	4.00
1 laborer, at \$2, tamping.....	2.00
Total, 31.7 cu. yds., at \$1.20.....	\$38.00

The tools used were as follows:

Two 7 x 7-ft. mixing boards, 7 wheelbarrows, 12 picks, 12 shovels, 6 hoes, 300 ft. of hose, 1 tamper, 12 lanterns and 1 tool box.

Binder.—The 1-in. binder course cost as follows:

	Per sq. yd.
Asphalt, at \$20 per ton.....	\$0.063
Binder stone, at \$2 per cu. yd.....	0.081
Labor and plant	0.045
Total	\$0.189

The 2-in. asphalt wearing surface was mixed in a plant having a capacity of 3 cu. ft. The tools used in connection with the wearing surface work consisted of a $3\frac{1}{2}$ -ton (30-in.) roller, a 300-lb. hand roller, a fire pot, 2 Watson wagons, 2 smoothers, 6 tamper, 6 shovels, 2 dirt picks, 6 asphalt picks, 3 rakes, 5 brooms and 4 wheelbarrows.

The cost of the 2-in. asphalt wearing surface was as follows:

	Per sq. yd.
Asphalt, at \$20 per ton.....	\$0.198
Sand, at \$1 per cu. yd.....	0.045
Dust, at \$10 per ton.....	0.090
Labor	0.090
Plant	0.198
Total	\$0.621

The high plant charge of 19.8 cts. was due in part to the mixing plant. This occupied two cars. In addition the job was very small, consisting of two 330-ft. by 46-ft. blocks.

The wages and organization of the gang engaged in the wearing surface work were as follows:

	Per day.
Superintendent, at \$5.....	\$ 5.00
Timekeeper, at \$3.....	3.00
1 engineman, at \$3.50.....	3.50
1 mixer, at \$3.....	3.00
1 mixer helper, at \$2.50.....	2.50
1 mixer dipper, at \$2.50.....	2.50
2 men shoveling to heater, at \$2.00.....	4.00
3 men wheeling, at \$2.....	6.00
2 teams hauling to streets, at \$4.....	8.00
2 rakers, at \$3.....	6.00
3 shovelers, at \$2.50.....	7.50
1 smoother, at \$2.00.....	2.00
1 tamper, at \$2.10.....	2.10
2 roller men, at \$2.50.....	5.00
1 engineman on roller, at \$3.50.....	3.50
1 man sweeping, at \$2.....	2.00
Total	\$65.60

The second piece of work was done in the fall of 1907 by private contract, at a contract price of \$1.89 per sq. yd. The work consisted of the construction of pavement on five blocks of streets and four alleys. The streets were 48 ft. wide, had a rise of 6 ins., and a grade of 1 per cent; they had no gutters. The alleys were 20 ft. wide and had a grade of 0.4 per cent to 1 per cent. The alley that had a 1 per cent grade drained well, but those where grade was less had to be ironed out. The alleys had no gutters. Experience in the city where this pavement was laid has shown that if the gutters fall more than $\frac{1}{4}$ in. to the foot they can be made to drain by using the straight edge. If the fall is less than $\frac{1}{4}$ in. there will be water holes. Where the gutter has to be raked it was found advisable to have double the fall per foot. The pavement consisted of 4-in., 1:3:6 concrete base, a 1-in. binder course and a 2-in. wearing surface.

Grading.—The grading was done by another contractor and cost \$0.699 per square yard, the work being done by the following force:

	Per day.
1 foreman, at \$3.....	\$ 3.00
1/2 timekeeper, at \$3.....	1.50
1 engineman, at \$3, part time on steam roller and part time plowing.....	3.00
2 teams plowing, at \$4.....	8.00
2 teams hauling dirt away, at \$4.....	32.00
12 laborers shoveling, at \$2.....	24.00
Total	\$83.50

Concrete Base.—The concrete base was laid by the contractor who did the grading. The concrete was mixed in a Ransome mixer, a 3 cu. ft. barrow of sand being dumped into the mixer first, then 1 cu. ft. of loose cement and finally two barrows of stone. After several turns of the mixer the mass was discharged and taken in scoops by the laborers and put in place. Two laborers spread the mixture, two laborers leveled it, and two more laborers tamped it. The mixture was as wet as it could be without the mortar running from the stone. Each wheelbarrow man had two helpers. The gang usually consisted of 28 men; 42 men were the most that could be used to advantage. The concrete on this job was better than that on the first job. The cost of the 4-in. concrete base was as follows:

	Per cu. yd.	Per sq. yd.
0.95 bbl. cement, at \$3.00.....	\$2.85	\$3.16
0.45 cu. yd. sand, at \$0.80.....	0.31	0.034
0.91 cu. yd. stone, at \$2.00.....	1.82	0.202
Labor and superintendence.....	0.974	0.108
Rent of machine, repairs, oil.....	0.246	0.027
Total	\$6.20	\$0.687

The stone used in the concrete was hauled from cars about 1/2 mile distant, the cost of unloading and hauling being as follows:

	Per cu. yd.
Foreman, at \$3.....	\$0.03
Laborers, at \$2.....	.16
Teams, at \$4.....	.19
Total	\$0.37

This cost is included in the \$2 in the table.

The wages and organization of the force engaged in mixing and placing the concrete base were as follows:

	Per day.
1 foreman, at \$100 per month.....	\$ 4.00
1 engineman on mixer, at \$2.50.....	3.50
1 handyman, at \$2.50.....	2.50
1 team, at \$4.....	4.00
1 laborer tending mixer discharge, at \$2.....	2.00
2 laborers carry and measure cement, at \$2.....	4.00
1 laborer at \$2 wheeling sand, and 1 laborer at \$2 helping.....	4.00
2 laborers at \$2 wheeling stone, and 2 laborers at \$2 helping	8.00
2 laborers dumping concrete, at \$2.....	4.00
2 laborers tamping, at \$2.....	4.00
3 laborers taking concrete from machine, at \$3..	18.00
Total, 40 cu. yds.	\$52.00

These concrete men evidently worked with no energy, as is shown by their miserably small output with a good plant.

The plant used consisted of a Ransome concrete mixer with 6 h.p. gasoline engine mounted on wheels, one 1 cu. ft. cement box, four 3 cu. ft. wheelbarrows, 29 scoops, 12 short-handled shovels, 18 long-handled shovels, 12 picks, 400 ft. of hose, three tampers, 12 lanterns and one tool box.

Binder.—The stone used in the binder had the dust screened out and was passed through a 1½ in. screen. It was found, however, that this did not leave enough fine stuff, pea size or thereabouts, so screenings from the sand were taken and from this was screened out all particles above 1 in. in size. One part of these screenings was mixed with two parts of broken stone and heated to 200° F. Four cubic feet of this was mixed with 27 lbs. of melted asphalt, making a strong binder. The cost of the binder was \$0.171 per square yard.

The wearing surface was mixed in batches of the proportion of 4 cu. ft. of sand, heated to about 300° F., 30 lbs. of cold dust, and 50 lbs. of melted asphalt. These were mixed very thoroughly, usually taking 1½ minutes to the batch. The mixture usually arrived on the street at about 280° F. It was found that a 4 cu. ft. batch would lay about 20 sq. ft. of 2 in. surface. The cost of the wearing surface was \$0.549 per square yard.

The wages and organization of the force engaged in preparing and laying the binder and the wearing surface were as follows:

	Per day.
Superintendent, at \$120 per month.....	\$ 5.00
1 engineman, at \$3.50.....	3.50
1 mixer, at \$3.00.....	3.00
1 mixer helper, at \$2.50.....	2.50
1 heater, at \$2.50.....	2.50
1 man shoveling sand and 1 man shoveling marble dust, at \$2.50.....	2.50
1 scraper team, at \$4.00.....	4.00
2 teams hauling to street, at \$4.50.....	9.00
1 engineman on roller, at \$3.50.....	3.50
2 rakers, at \$3.00.....	6.00
2 shovelers, at \$2.50.....	5.00
2 hand roller men, at \$2.50.....	5.00
2 tampers, at \$2.50.....	5.00
Total	\$56.50

The plant used consisted of a 4 cu. ft. mixer, a 5 ton (38 in.) roller, a 500 lb. hand roller, a fire pot, 3 Watson wagons and teams, a scraper, 3 rakes, 3 shovels, 2 tampers, 3 smoothers, 1 asphalt pick and 2 brooms.

Summary.—A summary of the costs of the two jobs is as follows:

	Job 1. Per sq. yd.	Job 2. Per sq. yd.
Grading	\$0.125	\$0.099
Concrete	0.791	0.687
Binder	0.189	0.171
Surface	0.621	0.549
Office, collection and general expense estimated	0.180	0.180
Total	\$1.904	\$1.686

Job 2 had more material and better workmanship per unit than Job 1. It was better managed, especially in the asphalt department. Job 1 had an asphalt mixer requiring two cars to move, while on Job 2 the mixer required but one car, but it cost more to move the latter. The small plant was the most economical. On concrete work the lost time of steady pay men when they were not mixing amounted to about 10 cts. per cubic yard; usually, however, when these men were not mixing they were engaged on other work.

Cost of 77,200 Square Yards Asphalt Pavement.*—Mr. F. E. Puffer gives the following.

The cost of laying 77,208 sq. yds. of asphalt pavement in an eastern city, which was a season's work, was as follows:

The price paid for common labor was \$1.50 a day, and \$5 a day for team and driver.

<i>Grading street:</i>	<i>Per sq. yd.</i>	<i>Total Per sq. yd.</i>
Sundries	\$0.021	
Labor	0.204	
Teams (\$5 a day)	0.087	\$0.312
<i>Concrete base (6-in.):</i>		
0.173 bbl. natural cement, at \$0.83	\$0.144	
0.055 cu. yd. sand delivered, at \$0.98	0.054	
0.176 cu. yd. stone delivered, at \$1.62	0.285	
Sundries	0.015	
Labor laying	0.094	
Labor, general	0.001	\$0.592
<i>Binder (1½ ins.):</i>		
Materials	\$0.188	
Fuel	0.016	
Tools and sundries	0.001	
Labor, yard (mixing, etc.)	0.026	
Labor, laying	0.022	
Labor, general	0.001	
Teams, hauling (\$5 a day)	0.024	\$0.279
<i>Surface (2-in.):</i>		
Materials	\$0.445	
Fuel	0.022	
Tools and sundries	0.054	
Labor, yard (mixing, etc.)	0.053	
Labor, laying	0.047	
Labor, general	0.028	
Teams, hauling	0.025	\$0.884
<i>General expense:</i>		
Salaries ..	\$0.018	
Rent and expenses	0.014	
Plant, etc.	0.025	\$0.057
Grand total		\$2.125

The exact proportions of the materials used in the binder and in the surface coats are not available, but the prices paid for materials and supplies were as follows:

Binder stone, per cu. yd.	\$ 1.00
Asphalt, per ton	50.75
Petroleum residuum, per gal.07%
Sand, per cu. yd.65
Pulverized limestone, per ton	3.50
Coal (anthracite) used in dryers, per ton	3.00
Coal (soft) used under boilers, per ton	2.85
Wood to heat asphalt tanks, per cord	4.00

**Engineering-Contracting*, Feb. 5, 1908.

It will be noted that the cost of the asphalt was much higher than it is at present, the present price being about \$30 a ton. Since there are about 4 lbs. of asphalt per sq. yd. of binder, and about 19 lbs. per sq. yd. of surface coat, the difference of \$20 a ton (or 1 ct. per lb. of asphalt) would reduce the above given costs by 4 cts. per sq. yd. of binder and 19 cts. per sq. yd. of surface coat.

An old plant having a value of about \$22,000 was used. The plant repairs amounted to \$1,525, or 2 cts. per sq. yd., which is unusually low. Ordinary plant charges are about 7½ cts. per sq. yd. where a modern plant is used, but in such cases the labor cost is lower than in this case. I have made no allowance for interest on and depreciation of plant.

The fallacy of attempting to estimate the cost of asphalt pavements from a single day's operation is clearly shown by comparing the records of costs on different jobs extending over considerable periods of time. Marked differences of cost occur, arising partly from variations in local conditions, and partly from the varying efficiency of the workers, and partly from the exactions of the inspector.

The following are the costs of three different streets, showing how costs vary.

Contract A was performed under favorable weather conditions on a suburban street, close to the source of supply of concrete materials and far from the paving plant. The cost was a little below the season's average above given:

CONTRACT A.
(3,284 sq. yds.)

<i>Grading street:</i>	Per sq. yd.	Total Per sq. yd.
Sundries	\$0.019	
Labor	0.123	
Teams	0.089	\$0.231
<i>Concrete base (6-in.):</i>		
Natural cement, at \$0.866 per bbl.	\$0.138	
Sand, at \$0.92 per cu. yd.	0.051	
Stone, at \$1.77 per cu. yd.	0.295	
Sundries	0.015	
Labor	0.092	\$0.592
<i>Binder (1½-in.):</i>		
Materials	\$0.192	
Fuel	0.011	
Tools and sundries	0.002	
Labor, yard	0.024	
Labor, laying	0.024	
Teams hauling	0.024	\$0.277
<i>Surface (2-in.):</i>		
Materials	\$0.673	
Fuel	0.026	
Tools and sundries	0.055	
Labor, yard	0.047	
Labor, laying	0.042	
Labor, general	0.029	
Teams hauling	0.035	\$0.907
General expense	\$0.042	\$0.042
Grand total		\$2.049

Contract B was the last contract of the season. Weather was unfavorable but not severe. Length of haul was less than the average for the season. The forces, except asphalt, were somewhat demoralized by the fact that the job would soon end. The cost was naturally high.

CONTRACT B.
(5,278 sq. yds.)

<i>Grading street:</i>	<i>Per sq. yd.</i>	<i>Total Per sq. yd.</i>
Sundries	\$0.021	
Labor	0.138	
Teams	0.139	\$0.238
<i>Concrete base (6-in.):</i>		
Cement, at \$0.845 per bbl.....	\$0.142	
Sand, at \$1.18 per cu. yd.....	0.063	
Stone, at \$1.93 per cu. yd.....	0.321	
Tools and sundries	0.015	
Labor	0.104	\$0.645

Fuel	0.011	
Labor, yard	0.030	
Labor, laying	0.026	
Teams hauling	0.025	\$0.287
<i>Surface (2-in.):</i>		
Material	\$0.666	
Fuel	0.023	
Tools and sundries	0.056	
Labor, yard	0.041	
Labor, laying	0.052	
Labor, general	0.029	
Teams hauling	0.035	\$0.903
General expense	\$0.057	\$0.057
Grand total		\$2.180

Contract C varies from the others in having a 1-in. binder and a 1½-in. surface specified. As a matter of fact, however, the asphalt was laid thicker than specified, due to the fact that the men had not been used to laying any light pavement that year. The work was located near the paving plant, also near the source of supply of cement, etc. The weather was good. The cost was naturally low.

CONTRACT C.
(2,404 sq. yds.)

<i>Grading street:</i>	<i>Per sq. yd.</i>	<i>Total Per sq. yd.</i>

Cost of Asphalt Pavements at Winnipeg.—The following data are given by H. N. Ruttan, City Engineer of Winnipeg, Manitoba, on the cost of laying asphalt with a municipally owned plant. In 1899, the city purchased a second-hand stationary plant for \$12,322, and made the following additions:

New 10-ton roller	\$ 3,500
New sheds, etc.	783
Tools bought 1899....	262
Tools bought 1900....	121
Maintenance 1899	568
Maintenance 1900	1,048
	<u>\$ 6,232</u>
Second-hand plant	12,322
Total	\$18,554

The maintenance items consisted largely in repairs to the second-hand plant necessary to put it in first-class condition. The plant includes 2 asphalt melting tanks, sand drum, cold and hot sand elevators, millstone for grinding limestone, storage tank for hot asphalt, storage bins for ground limestone and hot sand, mixer of 7 cu. ft. capacity, 60-hp. boiler, 30-hp. engine, air compressor and receiver, 5-ton roller, 10-ton roller, and accessories. The force required to operate the mixing plant was as follows:

1 superintendent	\$ 8.00
1 engineman	3.00
2 firemen	4.00
2 asphalt melters	4.00
1 asphalt dipper and mixer....	2.00
1 measurer of sand and limestone....	2.00
2 sand and limestone shovelers....	2.00
1 record keeper	4.00
1 man for odd jobs.....	2.00

Total labor for 9 hrs.....\$21.00

I have assumed the above rates of wages, but it is stated that the

total cost of operating was \$40 a day, which doubtless includes the cost of $1\frac{1}{2}$ or 2 tons of coal. It is stated that in 1900 the prices of materials and labor were as follows, on cars:

Asphalt, per short ton.....	\$26.00
Portland cement, per bbl.....	3.65
Sand, per cu. yd.....	1.35
Broken stone, per cu. yd.....	1.10

* Common labor is said to have been $17\frac{1}{2}$ to 20 cts. per hr.; teams, 40 cts. per hr.

Asphalt pavement, consisting of $1\frac{1}{2}$ -in. binder and 2-in. wearing surface, laid on a $4\frac{1}{2}$ -in. Portland cement concrete foundation, cost \$2.04 per sq. yd. for materials and labor. The concrete foundation cost \$0.74 per sq. yd., leaving \$1.30 per sq. yd. for the asphalt and the grading. It will be noticed that interest and depreciation are not included.

The plant has a capacity of 1,000 sq. yds. of 2-in. wearing surface, or 1,500 sq. yds. of $1\frac{1}{2}$ -in. binder, which is equivalent to saying that it has a capacity of about 60 cu. yds. of asphalt, measured in the street, per day of 9 hrs.

In 1899 the city laid 46,800 sq. yds.; in 1900, it laid 22,000 sq. yds. If we assume 30,000 sq. yds. as a fair average for a term of 10 years, the plant would pay for itself by charging 6 cts. per sq. yd. for plant, and it would be occupied about 60 days of actual work per year. But we should not lose sight of the fact that the services of an expert to run the plant could not be secured on the basis of a few dollars a day for only a small fraction of the year. Indeed the cost of an expert's annual salary alone might very easily run up the cost an amount equivalent to 10 cts. per sq. yd.

Since the above was written I have secured the following additional data for the year 1903. The plant has been enlarged and its estimated value is now \$21,082. The charges against this plant for the year 1903 were as follows:

Maintenance and repairs.....	\$2,297
$\frac{1}{4}$ cost of new tools.....	236
4% interest on \$21,082.....	843
6% depreciation on \$21,082.....	1,054
Lost taxes.....	100

Total plant charge, 65,381 sq. yds. at 6.93 cts..\$4,520

In 1903 there were laid 65,381 sq. yds., so that the charge for plant was 6.93 cts. per sq. yd. The soil is clay and upon it is spread 3 ins. of sand and gravel before laying the concrete base. The cost of the pavement in 1903, including grading, was as follows:

	Per sq. yd.
Grading, including cross-drains.....	\$0.15
Sand, 3-in. foundation.....	0.15
Concrete, $4\frac{1}{2}$ ins. thick.....	0.65
Binder coat.....	0.23
Surface coat.....	0.60
Plant charges.....	0.07
Total.....	\$1.90

The prices paid for materials, f. o. b. Winnipeg, in 1903, were as follows:

Portland cement, per bbl.....	\$ 2.96
Broken stone, per cu. yd.....	1.30
Sand and gravel, per cu. yd.....	1.00
Crushed granite, per cu. yd.....	5.00
Asphalt, per ton.....	26.87
Maltha, per imp. gal.....	0.12
Common labor, per 9-hr. day.....	\$1.80 to 2.25
Skilled labor, per 9-hr. day.....	3.70
Foremen.....	\$3.00 to 4.00
Superintending chemist (for 5 or 6 mos.).....	8.00

Mr. Rutten informs me that a 2-in. surface coat (Bermudes) costs as follows at the mixer:

	Per sq. yd.
0.06 cu. yd. (135 lbs.) sand, at \$1.35.....	\$0.081
21 lbs. dust, at \$2.60 per ton.....	0.027
3.5 lbs. oil, at 1½ cts.....	0.048
15 lbs. Bermudes (gross), at 1.93 cts.....	0.291
Labor at the mixing plant.....	0.048
Fuel (wood).....	0.018
Total, at the mixer.....	\$0.517

This gives a weight of 117 lbs. per cu. ft.

Cost of Laying Asphalt Pavement.—The following shows the labor cost of laying asphalt on a concrete base at Rochester, N. Y. A binder coat, ½-in. thick, was first laid; then a wearing, or surface coat 1½ ins. thick; making a total of 2 ins. The gang consisted of 16 men, working part of the time on the "binder" and part of the time on the "surface coat," as follows:

Binder gang.	Surfacing gang.
4 barrow loaders.	4 shovelers.
4 barrow wheelers.	5 rakers.
2 rakers.	2 tamperers.
2 tamperers.	2 smoothers.
1 wagon unloader.	1 cement spreader.
1 tar melter.	1 iron heater.
1 iron heater.	1 foreman.
1 foreman.	
16 men.	16 men.

The binder gang averaged 2,250 sq. yds. (= 31 cu. yds.) in 10 hrs. of ½-in. binder coat laid, although they frequently laid 390 sq. yds. in an hour. The surfacing gang averaged 1,800 sq. yds. (= 75 cu. yds.) of 1½-in. surface coat in 10 hrs., although they frequently laid 260 sq. yds. in an hour. There were two asphalt steam rollers constantly at work, with this gang of 16 men. In laying several thousand yards of this 2-in. asphalt pavement, I found the average labor cost to be as follows, the gang laying 1,000 sq. yds. per day:

15 laborers, at \$1.50.....	\$22.50
1 foreman, at \$4.00.....	4.00
2 roller engineers, at \$3.00.....	6.00
Fuel for rollers.....	2.50

Total for 1,000 sq. yds. of 2-in. asphalt, at 3½ cts...\$35.00

This is equivalent to 3½ cts. per sq. yd. for laying and rolling, or \$3 cts. per cu. yd.

The haul from the mixer to the street was 3 miles, and each

team made 4 trips daily, averaging only $1\frac{1}{2}$ cu. yds. of loose material per load. It took 2% cu. yds. of loose material in the wagons to make 2 cu. yds. packed by the roller, or a shrinkage of 25%. The wagons were flat-bottom wagons, and it took about 8 mins. to dump a wagon, but fully as much more time was lost waiting for other wagons, turning around, etc., which time was made up by trotting back. There were 17 teams kept busy, at \$3 per day each, making the cost 5 cts. per sq. yd. for hauling the asphalt 3 miles.

Cost of Asphalt Pavement, New York.*—In the following tabulation is given the labor cost to the contractor of laying 8,900 sq. yds. of asphalt pavement on Broadway, from 110th street to 119th street, west side, New York. The work was done in November, 1904. The wages paid were on the basis of an 8-hr. day. The concrete foundation for the asphalt pavement was 5 ins. thick and was composed of 1 part of cement, 3 parts of sand and 5 parts of broken stone. In preparing the concrete for the foundation a Foote mixer was used. The inefficiency of the concrete workmen is well shown by the following cost:

Concrete:	Per sq. yd.
0.008 day foreman, at \$3.75.....	\$0.03
0.162 day laborers, at \$1.50.....	.243
0.008 day teams, at \$5.00.....	.04
0.008 day steam engine, at \$3.50.....	.028

Total concrete labor, per sq. yd.....\$0.34

Binder:

0.0004 day foreman, at \$4.00.....	\$0.0016
0.0008 day engineman, at \$4.00.....	.0032
0.0062 day labor, spreading, at \$1.75.....	.011
0.0009 day labor, ramming, at \$2.25.....	.002

Total binder, per sq. yd.....\$0.018

Wearing surface:

0.0005 day foreman, at \$4.00.....	\$0.002
0.0040 day laborers, at \$1.75.....	.007
0.0010 day engineman, at \$4.00.....	.004
0.0070 day labor, spreading, at \$1.75.....	.012
0.0008 day labor, raking, at \$2.50.....	.002
0.0009 day labor, ramming, at \$2.25.....	.002
0.0016 day labor, ironing, at \$2.50.....	.004

Total surface coat, per sq. yd.....\$0.023

The binder was 1 in. thick, and the surface coat was $1\frac{1}{2}$ ins. thick, making a total of $2\frac{1}{2}$ ins. of asphalt. It will be seen that the laying cost of laying this asphalt was 1.8 cts + 2.3 cts = 4.1 cts. per sq. yd.

Cost of Patching Asphalt, Indianapolis, Ind.†—Mr. S. R. Murray gives the data upon which the following is based.

Work on the municipal repair plant of Indianapolis, Ind., was begun on April 16, 1908, and on June 16, 1908, the first asphalt mixture was turned out. The plant was made by Werthington & Berner and has a capacity of 1,200 sq. yds. of 2-in. asphalt. The total cost of the plant, one 5-ton steam asphalt roller, four dump wagons, fire wagons, office building, roller, stone dust and tool sheds and all tools

*Engineering-Contracting, May 16, 1904.

†Engineering-Contracting, Feb. 27, 1909.

necessary to carry on the work, amounted to \$20,557.68. This also includes the cost of grading off the yard for plant, putting brick driveway under mixer and cement floor around cold sand elevator. The plant itself cost \$15,535.

Between June 16 and Dec. 31, the following was the plant output:

	Boxes
Surface mixture	18,691
Binder	1,780
Total	18,421

A "box" was 9 cu. ft. of mixed material measured at the plant. Hence the total output was 165,789 cu. ft. of surface and binder, measured before rolling. With this there were laid:

	Sq. yds.
Surface, or wearing coat.....	92,472
Binder	11,271

It will be seen that each box (9 cu. ft.) of surface mixture made 5.54 sq. yds. of wearing surface, indicating that the wearing surface measured 2.17 ins. thick before rolling. If it was compressed 33% under the roller, the thickness was reduced to 1.45 ins. If it was compressed 16½% (a common assumption) the thickness was reduced to 1.8 ins.

The total cost of 82,908 sq. yds. of wearing surface (without any binder) laid in repairing 50 different streets was \$51,900, or \$0.625 per sq. yd. for all expenses, including interest, at 5%, on the \$20,600 plant for 6½ mos., and depreciation at 5% for 5½ mos.

This \$0.625 per sq. yd. is equivalent to \$3.46 per box of 9 cu. ft., or \$0.39 per cu. ft.

The work was done on the same basis as other city work, 8 hrs. per day, and was performed under the most favorable conditions, as a great many of the repairs were large and close together. Only one day was lost account of rain, and four days lost waiting for material.

Only seven hours were lost on account of the plant not being ready when called upon; two hours on account of the breaking of a driving pinion and five hours for replacing brick work in the furnace under the sand drier. This, it will be noted, is a very small loss of time when it is considered that the plant turned out 18,421 boxes in all.

Malta California asphalt was used for the most part on the repair work; but on account of the West Michigan St. being under guarantee and specifications calling for this material, Trinidad Pitch Lake asphalt was used in its resurface, which involved 9,500 sq. yds.

Petroleum residuum was used as a flux and the very best of material and workmanship were used throughout.

The cost of materials used in the plant was as follows.

California asphalt, \$23 per ton.

Trinidad asphalt, \$29 per ton.

Limestone dust, \$3 per ton.

Residuum oil, average 5 cts. per gal.

Sand, 90 cts. per cu. yd.

Common labor was paid 20 cts. per hour, skilled asphalt men re-

team made 4 trips daily per load. It took to make 2 cu. yds. per wagon. The wagons were slat-dump a wagon, but full other wagons, turning, trotting back. There was making the cost 5 cts. per

Cost of Asphalt Pavement is given the labor of asphalt pavement on west side, New York. wages paid were on the

received \$2.50 per 6-hr day. These were paid for at rate of \$3.50 per day. Further, engineers received \$1.50 per day, and foremen received \$1 per day.

High Cost of Patching Asphalt, New Orleans.—The total amount of asphalt pavement in New Orleans, maintenance of which by its contractors had expired prior to Jan. 1, 1901, was 549,749 sq. yds. Of this amount 292,536 sq. yds. is to be maintained by the city, and 157,213 sq. yds. by the New Orleans Ry. & Light Co.

In order to care for this pavement the city decided to erect a plant, and accordingly in 1904 asked bids for furnishing and erecting a repair plant. The specifications under which bids were asked gave the fullest latitude to bidders in designing the arrangement of the plant and in selecting the machinery, apparatus, fixtures, etc. It was, however, that the plant be operated with coal as a

ceived \$2.50 per 8-hr. day, teams were paid for at rate of \$3.50 per day, roller engineers received \$3.50 per day, and foremen received \$4 per day.

High Cost of Patching Asphalt, New Orleans.*—The total amount of asphalt pavement in New Orleans, maintenance of which by its constructors had expired prior to Jan. 1, 1908, was 549,749 sq. yds. Of this amount 398,536 sq. yds. is to be maintained by the city, and 151,213 sq. yds. by the New Orleans Ry. & Light Co.

In order to care for this pavement the city decided to erect a plant, and accordingly in 1904 asked bids for furnishing and erecting a repair plant. The specifications under which bids were asked gave the fullest latitude to bidders in designing the arrangement of the plant and in selecting the machinery, apparatus, fixtures, etc. It was required, however, that the plant be operated with coal as a

Fig. 12. Asphalt Plant.

fuel, and that it be capable of turning out each 10-hr. working day not less than 1,000 sq. yds. of binder when laid $1\frac{1}{2}$ ins. thick after compression on the street, or 1,000 sq. yds. of pitch asphalt wearing surface when laid 2 ins. thick after compression. The Warren Bros. Asphalt Paving Co., of Cambridge, Mass., was the only bidder, and on Dec. 5, 1905, its bid was accepted. The plant was accepted by the city on Aug. 21, 1906. A report on the operation of the plant for the year ending Aug. 31, 1907, has just been made by Mr. W. J. Hardee, City Engineer, and from this report has been taken the matter in this article.

The plant, Fig. 12, was erected in a lot of ground 175 ft. x 260 ft., owned by the city and formerly employed for garbage disposal purposes. The plant, furnished and erected by the Warren Bros. Asphalt Paving Co., covers about 1,500 sq. ft. of ground and consists of a building formed of concrete foundation, brick walls and floors and roof of steel beams, expanded metal and cinder concrete. The boiler and engine section is 1 story high; the dryer section and the asphalt melting tanks section are each 2 stories high, and the central or tower section, containing the sand bin, the mineral dust bin, and the mixer, is 3 stories, or 32 ft. high. The boiler and

**Engineering-Contracting*, Feb. 5, 1908.

engine, the dryer, and the asphalt melting tanks each have a substantial foundation of concrete, independent of the foundation of the buildings. The hot sand, or stone bin, and the mixer, together with their auxiliary apparatus, are carried on a conical-shaped steel frame, 4-legged tower erected just within the building and resting on pier concrete foundations independent of building foundations.

The cost of the plant and the appurtenant structures was as follows:

Demolition of old garbage plant buildings.....	\$ 475
Asphalt plant—Warren Bros. Asphalt Paving Co.'s contract, \$16,862.50; city alterations and additions, \$2,736.50	19,599
Yard fences and gates.....	859
Switch tracks	1,129
Yard pavements and drains.....	6,721
Tower tank and filter.....	1,330
Water pipes and outlets.....	1,015
Warehouse and platform	1,471
Asphalt shed	289
Blacksmith shop and equipment.....	223
Stable, rolling pen and wagon shed.....	5,311
Stone crusher and storage bin.....	1,966
Yard material bins	332
Office and store room building.....	5,509
Landing bins and roads.....	1,432
Lighting	352
General cleaning of premises.....	298
Total	\$48,345

Note.—No allowance is made for value of the land.

The live stock consist of 17 mules and 3 horses; the mules are used in wagons and carts and the horses in buggies.

The rolling stock consists of 10 Watson (2-cu. yd.) asphalt dump wagons; 8 (1-cu. yd.) single-mule dump carts; 2 Tennessee 4-wheel wagons with capacity of 4,000 lbs. each; 1 (4-wheel) float dray, 6-in. tires, with capacity of 6 tons; and 1 single-horse storm buggy. Each wagon and cart is equipped with a canvas (tarpaulin) cover.

In addition to 134 tools of various kinds necessary to operate the plant furnished by the Warren Bros. Asphalt Paving Co., the plant is equipped with the following: 1 Fairbanks platform scales mounted on rollers for weighing materials; 1 (4-wheel) 3 ft. 10 in. by 2 ft. 10 in. Fairbanks wagon hand truck; 12 iron frame and bed wheelbarrows; 6 short-handle shovels; 12 long-handle shovels; 19 axes; 6 picks; 8 crowbars; 8 sledgehammers, assorted sizes; and a number of small tools of various kinds.

The street tools consist of the following: 2 large-size tool boxes; 13 wooden street barriers; 1 Universal 8-ton steam asphalt roller; 1 Universal 3½-ton steam asphalt roller; 1 1,000-lb. iron hand asphalt roller; 1 (4-wheel) fire wagon for heating, tamping and smoothing irons; 1 (2-wheel) 100-gal. mixing kettle; 18 asphalt tamping irons; 15 asphalt smoothing irons; 66 asphalt axes; 107 picks; 13 mattocks; 102 long-handle shovels; 40 short-handle shovels; 24 iron frame and bed wheelbarrows; 6 axes; 200 lin. ft. of 1-in. diameter wire wrapped rubber hose; 8 sledgehammers; 3

chisels of various sizes; 10 crowbars; and a number of small tools of various kinds.

The testing laboratory, operated in connection with the plant, is equipped with cement testing apparatus, oil tester, brick tester, etc.

The cost of this equipment may be summarized as follows:

Live stock, harness and stable equipment.....	\$ 8,187
Rolling stock and equipment.....	3,180
Plant tools	837
Street tools	5,492
Office furniture	447
Laboratory equipment.....	1,490
Total	\$17,644

Soon after the plant was placed in operation the city ordered it to do a considerable amount of work not originally contemplated. This included the repairing of streets other than those paved with asphalt, and accordingly the following additional equipment was purchased:

Pioneer 7-ton steam road roller.....	\$1,113
Champion steel road grading machine.....	150
Austin 700-gal. capacity road sprinkler.....	398
Rolling stock	1,027
Railroad plows with extra points.....	29
Wheel scrapers	140
Harness	139
Live stock	1,760
Total	\$4,704

For the plow and grading machine mules 17½ hands high and weighing about 1,600 lbs. were secured.

Summarizing, the total cost of the plant and equipment is seen to be as follows.

Structures and their equipment.....	\$48,385
Equipment	17,672
Additional equipment	4,704
Total cost	\$70,583

The largest day's run made by the asphalt plant was on June 24, 1907, when surfacing (new pavement) the Esplanade-Claiborne Ave. intersection. In 9 hrs. 205 boxes, gross, of "wearing surface" mixture were turned out; 3 Watson wagons hauled this material from the plant to where it was laid, a distance of a little more than 2 miles; and this material completed 1,020 sq. yds. of pavement intended to be 2 ins. in thickness. The cost of the fuel and labor, including wages of plant foreman, employed in preparing the "wearing surface" mixture; the wages of wagon drivers and the care and feed of the teams; and the labor, including foreman, roller men and fuel, in laying this "naptha coat" and "wearing surface" amounted in all to \$127.23, or 12.47 cts. per sq. yd.

The repair plant force worked every working day of the year when it did not rain. The asphalt plant worked 141 days and turned out 9,883 boxes, or 88,947 cu. ft. of wearing surface mixture. It was estimated that a 9 cu. ft. box would lay 5 sq. yds. of 2-in. wearing surface, assuming that the loose material compresses 16½% under the roller. On this assumption 49,415 sq. yds. of 2-in.

wearing surface would have been laid. As a matter of fact, only 44,370 sq. yds. were laid, due to using a greater thickness than 2 ins. This greater thickness was necessitated because no "binder" coat was laid to replace any of the old binder removed from the street. Instead of a binder coat, the concrete was "painted" with a "naphtha coat."

Naphtha binder was not only much cheaper, but Mr. Hardee considers it also much more substantial and durable. Naphtha coat is formed of vaporized gasoline and asphalt mixed in equal proportions; it is put on the concrete foundation, when the same is perfectly dry, by hand, with brushes, just as paint would be applied, and to the least possible thickness; it is practically impervious to moisture and prevents the moisture that is commonly ever present in the concrete foundation of our pavements from attacking, through capillary attraction, the base of the asphalt "wearing surface" and rotting it; additionally, the "naphtha coat" effects a strong union of the concrete foundation and the asphalt "wearing surface" and prevents the latter from being displaced in warm weather, as is so frequently the case in old pavements in which gravel "binder" has been employed. In repairing old pavements, where the combined thickness of the "binder" and "wearing surface" was considerably more than 2 ins., concrete was generally added to the original concrete foundation.

From time to time such laborers, additional assistant foremen and other employees, as were required, were hired by the day. When operations were first commenced nearly all the plant and street employees were negroes, but as fast as white men who could satisfactorily do the work were found, the negroes were displaced; within a few months six negroes only remained and these were engaged at the plant on a class of work for which white men were not well

suited. Teamsters and some of the laborers were paid at the rate of \$1.75 per day; but the large majority were paid at the rate of \$2 per 10-hr. day. Pavers, stone workers and brick masons were paid from \$2.50 to \$4 per 8-hr. day.

The following is a list of the permanent employees:

	Annual wage.
Superintendent	\$ 2,500
Secretary	1,800
Stenographer	720
Street foreman	1,500
Assistant street foreman	1,200
Yard foreman	1,500
Engineman	1,500
Fireman	780
Steam roller engineman	1,380
Blacksmith	1,080
Yard clerk	720
Messenger	800
Hostler	720
Night watchman	720
Veterinary	180
Chemist, $\frac{1}{2}$ of \$1,800	900
Chemist helper, $\frac{1}{2}$ of \$720	360
Total	\$18,160

For reasons that are not made at all clear in his report, Mr. W. J. Hardee, City Engineer, deducts the following salaries from the above, and puts them in an account that he designates by the very ambiguous phrase "Special Charges":

Chemist	\$ 720
Chemist helper	310
Engineman	1,450
Fireman	725

Total salaries in "Special Charges".....\$3,205

Deducting this \$3,205 from the annual salaries of \$13,160, we have left \$14,955, which somehow becomes \$15,674 when recorded in the "Annual Employees' Salaries."

Then the account of "Special Charges" contains the following:

Salaries (as above given).....	\$ 3,205
1/2 laborer's wages at the plant.....	8,092
342 tons coal at the plant, at \$2.84.....	972
Supplies at the plant	606
Wood at the plant.....	76
Gas and laboratory supplies.....	16
Damaged cement	100

Total "Special Charges".....\$13,067

Then under an account designated as "General Charges" is placed the \$15,674 of "annual employees' salaries," also "one-half day laborer's wages at the plant"; but, unless the purpose is to confuse the analyst of these costs, there appears to be no sound reason for separating the "plant labor" into two halves, as is thus done.

The following is the statement of "General Charges":

Annual employees' salaries.....	\$15,673.96
One half day laborer's wages at plant.....	8,092.35
Live stock feed.....	3,032.78
Electric lighting	331.75
Electricity for crusher.....	133.35
Water at plant.....	300.00
Water on street.....	163.50
Blacksmith's supplies	87.52
Office supplies	436.00
Stable supplies	809.30
Horseshoeing	494.70
Extra teams.....	1,629.10
Car fare and incidental expenses.....	570.90
Lost and worn-out tools.....	265.80
Lost live stock.....	270.00

Total "General Charges".....\$31,790.99

The cost of 300 cu. yds. of concrete and 35,905 sq. yds. of "wearing surface" supposed to be 2 in. thick, was as follows per sq. yd. of 2-in. asphalt wearing surface:

	Total	Per sq. yd.
Materials	\$15,279	\$0.425
Special Charges (pro rated).....	6,761	0.189
General Charges (pro rated).....	11,090	0.309
Other labor	7,177	0.200
Total, Repairs to Asphalt.....	\$40,307	\$1.123

As I shall show presently, there is no valid excuse for prorating the "Special Charges" or the "General Charges" in this manner.

In addition to the above given repairs, 8,400 sq. yds. of new asphalt pavement, on a 6-in. concrete base, were laid, and excavation made for the same, at the following cost:

	Total.	Per sq. yd.
Materials (asphalt and concrete materials)	\$12,130	\$1.444
Special Charges (pro rated)	6,205	0.750
General Charges (pro rated)	10,342	1.231
Other labor	8,812	1.050
Total, New Pavement.....	\$37,589	\$4.475

This is "saving the contractor's profits" with a vengeance. A cost of \$4.48 per sq. yd. of 2-in. asphalt on a 6-in. concrete base, is approximately three times what it would cost any capable contractor. Bear in mind, also, that the \$4.48 does not include any allowance for plant interest and depreciation.

Finally, in addition to the asphalt repairs and the new asphalt pavement above given, there was a considerable amount of "Miscellaneous Improvements," such as curb setting, repairing with crushed stone, grading, filling, and the like, the total cost of which was:

Materials	\$13,854
General Charges (pro rated)	10,364
Other labor	7,129
Total, Miscellaneous Improvements.....	\$31,347

Analysis of the above costs discloses how the "special charges" and the "general charges" were prorated, namely, according to the cost of the materials used on the three classes of work, i. e., on (1) repairs, (2) new pavement, and (3) miscellaneous. A more absurd distribution could not be imagined, for here is an expensive (\$70,000) asphalt plant, with 34% of its "general charges" prorated to curb setting, grading, etc.! Were this not done, the costs of the asphalt repairing and new pavement would show up even higher than they do in the above tabulations.

I have arranged the cost of materials and supplies used during the year, under five heads, as follows:

Asphalt Materials and Supplies:

465.99 tons asphalt, at \$18.50	\$ 8,561
125,527 lbs. fluxing oil, at 7½ cts.	940
6,753 gals. naphtha, at 15 cts.	1,019
3,900 cu. yds. sand, at \$1.27	4,953
221 tons mineral dust, at \$5.50	1,764
289 tons coal, at \$2.84	1,105
90 cords wood	553
Total asphalt materials.....	\$18,905

Concrete Materials:

1,936 bbls. cement, at \$2.04	\$ 3,944
700 cu. yds. sand, at \$1.27	889
564 cu. yds. gravel, at \$2.27	1,272
696 cu. yds. brickbats (for crushing), at \$1.48	1,032
Total concrete materials.....	\$ 7,137

Miscellaneous Materials:	
3,178 cu. yds. clay gravel, at \$1.50.....	\$ 4,767
2,618 cu. yds. lake shells, at \$1.46.....	5,304
3,200 new granite blocks, at 7 cts.....	227
4,600 old granite blocks, at 4 cts.....	184
9,000 new building brick.....	98
8,600 old building brick.....	25
82,924 lbs. cast iron.....	1,389
3,028 lin. ft. drain pipe.....	979
Total	\$12,893
Office Supplies:	
Laboratory	\$ 24
Office	426
Engineer	606
Total supplies	\$ 1,056
Stable:	
122,172 lbs. oats, at 1 1/4 cts.....	\$ 1,820
6,600 lbs. bran, at 1 ct.....	66
39 3/4 tons hay, at \$24.72.....	983
Stable supplies \$309, blacksmith \$87.....	396
Total stable	\$ 3,265
Grand total	\$43,265

These prices are all for materials delivered at the plant.

The foregoing distribution, under the five heads, may be slightly in error. The sand, for example, is given as 4,600 cu. yds., without statement as to its use. About 1,400 cu. yds. of new concrete base were laid, which would require about 700 cu. yds. of sand, and I have, therefore, distributed it in that manner, although there was a certain small, but unstated, amount of concrete laid on old concrete base to bring it up to grade.

This distribution of the cost of materials shows conclusively the absurdity of prorating the "General Charges" and "Special Charges" according to the cost of materials. A glance at the items under "Miscellaneous Materials" proves that no appreciable part of the cost of operating a \$70,000 asphalt plant should be properly prorated to "Miscellaneous Improvements," as was done. It is true that a rock crusher (which crushed only 1,143 cu. yds. of stone and brick-bats during the year) and a road machine, and a few tools (worth about \$2,000, exclusive of mules) were used on the "Miscellaneous Improvements"; but so insignificant was the plant necessary for that work that it is manifestly wrong to prorate any asphalt plant charges or any asphalt plant operating expense to these "Miscellaneous Improvements." I have been at some pains to point out these details, for it is a very common practice for managers of municipally operated plants to conceal the true costs of operation by prorating charges in this fashion. The following is my own analysis of the year's operating expense, which errs, if at all, on the side of liberality toward the managers of this municipal plant. I shall not include the cost of the grading nor of the concrete for the new pavement laid, but confine the summary only to the cost of asphalt repairs, giving total costs, and cost per "box" (9 cu. ft.) of wearing surface, there being 9,883 boxes (88,947 cu. ft.), equivalent to 49,415 sq. yds. 2 ins. thick after rolling:

	Total.	Per box. (9 cu. ft.)
Salaried employees	\$18,160	\$1.833
Laborers' wages at plant	16,184	1.637
<i>Feeding Stock, Etc.:</i>		
Feed for regular teams	\$ 3,023	
Blacksmith supplies	88	
Stable supplies	309	
Horse shoeing	495	
Lost live stock	270	
Extra teams hired	1,629	
Total, feeding stock, etc.	\$ 5,824	\$0.689
<i>Street Labor, Teamsters, Etc.</i>		
On 35,900 sq. yds. repairs	\$ 7,177	
On 2,400 sq. yds. new 2-in. surface (estimated) ..	1,780	
Total street labor, teamsters, etc.	\$ 8,957	\$0.907
<i>Office Expense, Etc.:</i>		
Engineers' supplies	\$ 606	
Office supplies	436	
Laboratory supplies	24	
Total office expense, etc.	\$ 1,064	\$0.107
<i>Asphalt Materials and Supplies:</i>		
465.99 tons asphalt, at \$18.50	\$ 8,561	
125,527 lbs. fluxing oil, at 7 1/2 cts.	940	
6,753 gals. naphtha, at 15 cts.	1,019	
2,900 cu. yds. sand, at \$1.27	4,953	
321 tons mineral dust, at \$5.50	1,764	
289 tons coal, at \$2.84	1,105	
90 cords wood	563	
Total asphalt materials and supplies	\$13,905	\$1.914
<i>Miscellaneous Plant Expense:</i>		
Electric lighting	\$ 332	
Water	300	
Lost tools, etc.	266	
Total miscellaneous plant expense	\$ 898	\$0.091
<i>Plant Charges:</i>		
Interest, 5% of \$65,000	\$ 3,250	
Depreciation, etc., 10% of \$65,000	5,500	
Total plant charges	\$ 9,750	\$0.987
Grand total	\$79,724	\$8.076

Note.—I have made no allowance for "ground rental."

Upon Mr. Hardee's assumption that a "box" of wearing coat will lay 5 sq. yds. of 2-in. wearing coat, we have simply to divide all the above items of "cost per box" by 5, to arrive at the cost per sq. yd., which summed up is as follows:

	Per sq. yd.
Salaried employees	\$0.868
Laborers' wages at plant	0.327
Feeding stock, etc.	0.118
Street labor, teamsters, etc.	0.181
Office expenses, etc.	0.021
Asphalt materials and supplies	0.383
Miscellaneous plant expense	0.019
Plant charges	0.198
Total	\$1.614

The item of plant charges (interest, depreciation and repairs) does not appear in the report of the city engineer, although such an item should always appear, nor is there any allowance for interest on the ground occupied, although it certainly had value. I have assumed the conventional 5% interest and 10% depreciation and repairs on \$65,000 plant (omitting about \$5,000 of plant used on "Miscellaneous Improvements"). It should be noted that the first cost of this plant is unusually high.

A small part of the item of "Feeding Stock, Etc.," should unquestionably be charged to "Miscellaneous Improvements" and to hauling materials for concrete, but I am unable to segregate the amount, which is inconsiderable anyway.

The item of "Street Labor, Teamsters, Etc.," is exact for the \$5,900 sq. yds. of repairs, but the report gave no details that would enable one to arrive at the corresponding cost for the 8,400 sq. yds. of asphalt laid on the new concrete base, so I have prorated it at the same cost as for the \$5,900 sq. yds. of repairs, namely at 20 cts. per sq. yd. This cannot be far wrong, and, in any event, the new pavement was less than 20% of the total wearing coat.

We have in this work the highest cost of 2-in. asphalt wearing coat of which I have any knowledge. It even exceeds the cost of Brooklyn municipal work. It forms, indeed, an object lesson of the gigantic folly of doing public work with a municipal plant instead of by contract.

Note especially the fact that my analysis of the true cost of this repair work shows \$1.61 per sq. yd., as contrasted with the \$1.12 (which, even at that, was an enormously high cost). By improper prorating of "general and special expenses" and by entire omission of any plant interest and depreciation charges, ground rental, etc., it is an easy matter always to give an appearance of lower unit costs than actually exist.

In *Engineering-Contracting*, April 7, 1909, is given an abstract of Mr. W. J. Hardee's report for the year 1908, relating to this same plant. The following is a brief summary:

Repairs of asphalt pavements.....	\$ 27,545.69
New asphalt pavements.....	14,409.33
Other kinds of new pavements.....	23,445.84
Miscellaneous improvements	74,398.91

Total\$139,799.67

The repair work consisted of the construction of 2,640 sq. yds. of naphtha coat and 24,081 sq. yds. of asphalt wearing surface, the cost per square yard of wearing surface being as follows:

	Total.	Per sq. yd.
Materials	\$ 8,631	\$0.367
Labor	6,778	0.281
Proportion special charges.....	3,153	0.131
Proportion general charges.....	8,784	0.364
Total	\$27,546	\$1.143

It will be noted that the same misleading method of prorating "special and general charges" was used, and that the unit cost of these repairs exceeded the cost of work done the previous year.

The new asphalt pavement work consisted in the construction of 7,558 sq. yds. of pavement, the work including 14,520 cu. ft. of concrete, 7,500 sq. yds. naphtha coat and 7,500 sq. yds. 2-in. wearing surface. The gross cost of this was \$14,409 or about \$1.90 per sq. yd.

The other new pavement work consisted in the construction of vitrified brick and gravel roadways, the total cost of the work being \$23,445.84. The largest item of work was for miscellaneous improvements, these consisting of graveling roads, constructing oyster shell pavement, grading, etc. The total cost of these miscellaneous improvements was \$74,398. The output of the plant was 86,004 cu. ft. (9,778 boxes) wearing surface mixture, which was employed in new pavements and repair of old pavements. The crusher operated in connection with the asphalt plant crushed 7,834 cu. yds. of old stone at an average cost for labor and electricity of 51.4 cts. per cu. yd. The stone was furnished free of charge. The cost per cubic yard in the previous year was 46.66 cts. Including feed, hostler and stable boy's wages, veterinary's salary, shoeing, medicine, etc., it cost an average of 76 cts. per head per day to feed and care for the live stock, as against 64.9 cts. for the year ending Aug. 31, 1907.

In the first annual report the cost of the plant including equipment is given as \$79,583. Additions to the plant costing \$4,261 were made in the second year, bringing the total investment for plant and equipment up to \$74,844. The asphalt cost \$19 per ton delivered.

Cost of Patching Asphalt, Marion, Ind.*—Mr. T. E. Petrie gives the following:

The accompanying data relate to repair work in the city of Marion, Ind., throughout the month of September, 1908. This is a very good average of the season's work, after the force was thoroughly organized and all equipment put into service.

A city of the size of Marion could not afford a plant costing upwards of \$20,000, which would possibly remain idle eleven months out of the year; so we had to look for a smaller and less expensive repair plant. We have in our city 6.84 miles of asphalt streets, or 123,486 sq. yds. The first street was constructed in 1899 and the last in 1902. While we have some excellent asphalt streets, some are much below the average. We found in past experience that to rely on the asphalt companies to do our repair work, it was necessary that our streets should become quite bad before any company would agree to come in to do our repair work, as the repair yardage was so small that it would not pay them to move their plant to our city, so we could expect them once in two or possibly three years, even though the street was under guarantee.

In the spring of 1908, even though two of our streets were yet under guarantee, our Board of Public Works came to an agreement with the Barber Asphalt Co. that the city should take care of all streets under guarantee and that the Barber Asphalt Co. would relinquish all retainer claims that they held against the city.

**Engineering-Contracting*, Feb. 16, 1909.

In the meantime three of our streets became quite bad, so we began to look about for some relief, and finally purchased one of Hooke's largest combined asphalt plants and a carload of asphalt. To this plant was added another pan and a 700-lb. hand roller.

The cost of the plant was as follows:

Combined fire wagon and asphalt heater.....	\$465
Freight	42
Extra pan	43
Hand roller	65
Hand cart	10

Total cost of plant\$625

Depreciation on the plant was figured on the basis of 60 days' use for the season. This, at 10 per cent, amounted to \$62.50 or \$25.73 for the 25 days for which the cost records are given.

We began work July 20, 1908, and finished or rather run out of material, Nov. 28th. While not working quite all the time we laid 4,142 sq. yds. of patch work. Great care was taken about the work and it is almost impossible to detect many places where patches were made. We used the Acme asphalt, which came already fluxed, and three grades of sand, so as to obtain as nearly a standard mix as possible, as well as to make the mixture as dense as possible.

We used Portland cement as a filler, instead of stone dust, which caused the price per sq. yd. to run up somewhat higher than it would have had stone dust been used.

We had two experienced men in the gang and paid them 25 cts. per hour, all other men were paid 20 cts. per hour. A one-horse dump cart was used for hauling material from stock room to plant, also hauling prepared material to street, and cuttings or old asphalt away, usually hauling same on some nearby street as repairing material. The cart man was paid 27½ cts. per hour.

The full repair gang consisting of 3 men, 2 out on the street and 1 at the plant, and 1 horse cart and driver.

Orders were given to work until the pans were cleaned and filled with sand at the end of each day's work, ready for fire the next morning.

Four-foot wood was generally used for firing, costing \$5.50 per cord, yet some shorter wood was used, costing \$1.75 per cord. The Portland cement cost \$1.40 per barrel; sand cost \$0.75 at the plant and the asphalt cost \$30 per ton f. o. b. Marion.

During the 25 working days in September a total of 1,308 sq. yds. of asphalt pavement of an average depth of 2 ins. was laid, there being 2,742 cu. ft. of asphalt mixture used, costing 41 cts. per cu. ft. laid. The itemized cost was as follows:

	Total.	Per sq. yd.
Labor	\$ 483.64	\$0.3697
Asphalt (including freight), at \$30 ton.....	340.34	.2602
Sand, at \$0.75	70.12	.0534
Cement (instead of dust)	98.17	.0759
Fuel	72.93	.0557
Cartage, 30 tons asphalt	11.22	.0086
Interest, 6%	15.00	.0114
Depreciation, 10%	25.72	.0120
Total	\$1,117 14	\$0.8538

Last season was an excellent one to do repair work, on account of there being but little rain. The sand was kept as dry as possible, and therefore was covered at night, and at daytime in case of rain. This materially assisted in the progress of the work as well as in the saving of much fuel.

The plant was located at some convenient point, near where considerable patching was to be done and care was taken not to move the plant too frequently, as this expense will cause the price per square yard to rise quite rapidly. We were able to get out eight batches per day, providing everything worked well. It is intended to enlarge the mixing pans before beginning work this season, and by so doing it is hoped to increase the output fully 25 per cent, and by using stone dust instead of Portland cement for filler, to cut the price down to at least \$0.75 per sq. yd. or perhaps lower.

There has been nothing allowed for superintendence of the work as either the city engineer or his assistant will have time to see that work is going on as it should. However, last season I gave this work quite considerable attention, measuring all patches made, as I desired to know just what it was costing per square yard.

I do not anticipate that we will have as much repair work in the next two seasons as we had last season.

Cost of Patching Asphalt, Marion, Ind.*—In 1908 the city of Marion, Ind., had 6.84 miles of asphalt streets or a total of 123,486 sq. yds. of that kind of pavement. In that year the city took over the maintenance of all of the asphalt paved streets and purchased one of Hooke's largest combined asphalt plants for the work. To this plant was added another pan and a 700-lb. hand roller. The cost of the plant in 1908 was as follows:

Combined fire wagon and asphalt heater.....	\$465
Freight	42
Extra pan	43
Hand roller.....	45
Hand cart	10
Total	\$625

In 1908 a total of 4,142 sq. yds. of patch work was laid. Further details of that year's work are given in our issue of Feb. 10, 1909.

Before beginning work in 1909 a new bottom was put in the Hooke pan, and it was also enlarged so that a batch of 16 5/8 cu. ft. of loose mixture was turned out for the 1909 work, instead of 14 1/2 cu. ft. as in 1908. This should have increased the output as well as decreased the labor cost. Owing, however, to the fact that a different brand of fluxed asphalt was used in 1909, which, for the same amount of mixture, took about 25% more asphalt, the

**Engineering-Contracting*, Dec. 15, 1909.

material expense was increased, and also the labor cost as it took considerably longer to mix a batch.

In the 1909 work stone dust was used as a filler, whereas in 1908 Portland cement was used for this purpose. In this year's work the Portland cement was used as a top covering only.

The working force consisted of the following:

Plant:

1 man at 25 cts. per hr.
4 men at 20 cts. per hr.

Street:

1 man at 25 cts. per hr.
2 men at 20 cts. per hr.

A one-horse dump cart was used for hauling material from stock room to plant, also for hauling prepared material to street and cuttings or old asphalt away. The driver was paid 27½ cts. per hr. This was the same gang as in the 1908 work with the exception of one man. The men, however, were not as energetic to push the work, as they were in the previous year and this brought up the labor cost. In addition the patches were smaller in the 1909 work and this also caused the labor cost to increase, as when many small patches were made in succession the gang at the plant would be compelled to hold back waiting on the men on the street to prepare places to receive the material.

The working season in 1909 was 33 days, and in that time the gang placed 1,451.5 sq. yds. of patches of an average depth of 2 ins. This is an average of about 44 sq. yds. of patchwork per day. A total of 2,828.1 cu. ft. of loose mixture was produced in the season of 33 days or an average of 85.5 cu. ft. per day. This would be an average of about five patches per day, there being 16 5/8 cu. ft. to a patch. As 2,828.1 cu. ft. of loose mixture made 1,451.5 sq. yds. of compacted 2-in. patches, there was about 1.95 cu. ft. of loose mixture per square yard of 2-in. compacted asphalt. This is 1.3 cu. ft. of loose mixture compacted down to 1 cu. ft. For fuel cord wood was used, 16.8 cords being used for this purpose. As the season covered 33 days the average amount of wood consumed per day would be about ½ cord. As there was an average of five batches per day there was about 0.1 of a cord of wood used per batch.

The cost of the various materials used in the work in 1909 was as follows:

Asphalt, including freight, per ton.....	\$28.714
Sand at plant, per cu. yd.....	0.75
Cement, per bbl.....	1.40
Stone dust, including freight and drayage, per ton	3.52
Cordwood for fuel, per cord.....	4.50

Interest on the plant investment was figured at 6% per annum, or \$37.38 for the year. Depreciation on the plant was figured at 10% per annum, or \$62.50 per year.

The itemized cost of materials in the asphalt surface was as follows:

	Per sq. yd. 2 ins. thick.
27.17 lbs. fluxed asphalt, at 1.43 cts.....	\$0.388
14.47 lbs. stone dust, at .176 cts.....	.026
.069 cu. yds. sand, at 75 cts.....	.052
.0033 bbls. cement, at \$1.40.....	.005
Total materials for surface.....	\$0.470
Labor, at 20 and 25 cts.....	\$0.426
Wood, 16.8 cords, at \$4.50.....	.052
Cartage of asphalt.....	.005
Interest on plant.....	.026
Depreciation on plant.....	.043
Grand total	\$1.022

The average cost per cubic foot material and labor was 52½ cts.

A comparison of the 1908 costs and the 1909 costs may be of interest and accordingly we have abstracted the costs from the former year as given in our issue of Feb. 10, 1909. The costs for 1908 are for 25 working days in September, during which 1,303 sq. yds. of asphalt of an average depth of 2 ins. was laid. The costs in the two years were as follows:

	1908. Per sq. yd.	1909. Per sq. yd.
Labor	\$0.3697	\$0.426
Asphalt2602	.388
Sand0536	.052
Cement0750	.005
Stone dust026
Fuel0557	.053
Cartage0036	.005
Interest0114	.026
Depreciation0190	.043
Total	\$0.8537	\$1.022

In the 1908 work the asphalt, including freight, cost \$30 per ton, and wood cost \$5.59 per cord. With these exceptions the prices for material and labor are the same as in 1909. Portland cement was used for a filler in 1908, whereas stone dust was used in 1909. In the figures for the 1908 work the depreciation was figured for the 25 days in September only on the basis of 60 days' use for the season; while in the 1909 costs the depreciation is for the entire season.

All of the work was done under the direction of T. E. Petrie, city engineer.

High Cost of Patching Asphalt, Brooklyn, N. Y.—In *Engineering-Constructing*, May 27, 1908, a complete description is given of the municipal asphalt plant in Brooklyn, which was placed in operation, June 13, 1907. The plant was constructed by the Warren Asphalt Paving Co. A 60 h.p. Babcock and Wilcox boiler, and a 16 h.p. engine (Erie Engine Works) and a 9 h.p. engine (Sturdevant Blower Works), furnish the power. Without going further

into details of design, the following summary gives the cost of the plant:

Contract price	\$22,485.60
Engine and boiler foundations, piles, etc.....	509.54
Office and sheds	712.00
Fire ext'ing	150.00
Oil tank	365.00
Extra parts—machinery	411.76
Office furniture and equipment.....	174.28
Electrical work, wiring, lights, annunciators..	58.80
Four asphalt rollers	6,156.00
Twelve asphalt trucks at.....	4,920.00
Tools and gang equipment.....	2,000.45
Miscellaneous	327.35
Total	\$38,280.18

Fixed Charges.

Interest on payments on above at 5%.....	\$ 297.10
Depreciations on plant at 10% ($6\frac{1}{2}$ months) on \$37,892.08	2,052.49
Rent of plant grounds, \$1,440 per year, 7 mos.	840.00
Total per annum	\$ 3,789.59

The plant was in operation $6\frac{1}{2}$ mos., in 1907, beginning June 13, 1907, and there were 134 working days out of 202.

The output of the plant was 5,951 boxes of wearing surface mixture and 1,524 boxes of binder, total 3,475 boxes. Each of these boxes held 8 cu. ft. of the mixed product, as measured at the plant. It was found that, during the hauling in wagons from the plant to the street, the wearing surface mixture consolidates and looses about 3% of its volume, but the binder mixture does not consolidate appreciably.

The average wagon load is 8 boxes, or 72 cu. ft. of mixture, and the average distance from the plant to the point of repairs was 4.14 miles. Observations on 25 loads showed a traveling speed of only 2.15 miles per hr. A team and wagon cost \$6 per 8 hr. day. The cost of hauling, as given below, includes all delays at the plant and on the street, as well as the cost of hauling the old asphalt from the street to the dump, but it does not include the cost of hauling any materials to the plant, for all prices of materials include delivery at the plant. The wages for an 8 hr. day were:

Plant foreman	\$6.00
Foreman	4.00
Rakers	2.50
Tampers	2.50
Smoothers	2.00
Laborers	2.00
Team (with driver)	8.00

In making a box of wearing coat 0.3 cu. yd. of net measure of sand was used, but allowing for losses in the yard, shrinkage on drying, etc., 0.4 cu. yd. of sand were bought. According to the statement of total weight of stone dust used, there were 84 lbs. per box, but, according to the cost per box, at \$3.50 per ton, it would appear that 63 lbs. were used.

No record was kept of the number of square yards repaired, the

"box" (9 cu. ft.) being the unit of record. For purposes of comparison, however, I have assumed that a 9 cu. ft. box of wearing surface would make 5 sq. yds. of wearing surface measuring 2 ins. thick after rolling. If 9 cu. ft. of loose wearing surface shrinks $\frac{1}{6}$, or 16½%, under the roller, we have 7½ cu. ft. of compacted wearing surface, which will make exactly 5 sq. yds. 2 ins. thick. However, careful measurements on 27 sq. yds. made in 1906 by Mr. John C. Sheridan, Chief Engineer of the Bureau of Highways of Brooklyn, showed the following:

"When the concrete foundation was completed ordinates were taken every few feet from a line stretched from curb to curb. These sections were taken about 2½ ft. apart. After the 1-in. binder was laid, measurements were made from the line over the same points, and after the 2-in. wearing surface was laid, similar measurements were taken at the identical points, the material having previously been measured in the truck. It was found that there was a shrinkage of 21½ per cent from the loose measure in the truck to the measurement compacted in place, and that there was a shrinkage of 33 per cent from the plant measurement to the measurement compacted in place. This was on the wearing surface; the shrinkage in binder was not determined."

If we were to assume the greater shrinkage indicated by this experiment, instead of the 16½% shrinkage from the measurement at the plant, we should get a very much smaller yardage of 2-in. pavement, and a correspondingly higher cost. I prefer, therefore, to give the benefit of the doubt to the managers of the Brooklyn municipal plant, by assuming that a 9 cu. ft. box will make 5 sq. yds. of 2-in. wearing coat.

The following costs per box, are as I have deduced them from the annual report for 1907, and the costs per sq. yd. are based upon the assumption just stated.

COST OF WEARING SURFACE.

	Per box. (9 cu. ft.)	sq. yd. (2-in.)
Materials:		
0.4 cu. yd. gross (0.3 cu. yd. net) sand at \$0.75..	\$0.299	\$0.060
62 lbs. stone dust at \$3.50 ton.....	0.110	0.022
13 lbs., or 1.63 gals. flux at 6% cts. per gal.....	0.121	0.024
91 lbs. asphalt at \$24.80 ton.....	1.127	0.225
Total materials	\$1.657	\$0.331
Supplies:		
0.037 tons soft coal for plant at \$4.00 per ton.....	\$0.148	\$0.030
0.0056 tons hard coal for rollers at \$5.50.....	0.031	0.006
Oil and waste	0.030	0.006
0.008 cords wood for street fire wagon at \$11.34....	0.091	0.018
Miscellaneous supplies	0.030	0.006
Total supplies	\$0.330	\$0.066

COST OF WEARING SURFACE (CONTINUED).

<i>Plant Charges:</i>	Per box. (9 cu. ft.)	Per sq. yd. (2 in.)
Rent	\$0.099	\$0.020
Dump privileges	0.018	0.004
Interest on plant, 5% per yr.....	0.106	0.021
Depreciation, 10% per yr.....	0.242	0.048
Repairs to plant	0.091	0.018
Repairs to tools	0.024	0.005
Total plant charges.....	\$0.580	\$0.116
<i>Labor:</i>		
Plant labor (including foreman).....	\$1.438	\$0.288
Hauling, 4.14 miles	0.934	0.187
Street labor (including foreman)	2.356	0.471
Superintendent (\$1,363 for $6\frac{1}{2}$ mo.).....	0.161	0.032
Total labor	\$4.889	\$0.978
Grand total	\$7.456	\$1.491

Attention should be called to the fact that this plant is new, and that repair costs are therefore smaller than they will be later on. There is apparently nothing included for chemist's salary, etc. Nevertheless, the cost of \$7.45 per "box," or \$1.49 per sq. yd. of 2-in. surface, is enormously high. Note particularly the tremendously high cost of each of the labor items, except the superintendent. Here is a cost of almost \$1.00 per sq. yd. for labor alone on a 2-in. wearing surface! Compare this with records given elsewhere in this book. Even the outrageously high cost of similar municipal work at New Orleans is outdone by this municipal asphalt repairing in Brooklyn. (See page 402.) However, they are both typical of municipally-operated plants.

The cost of the binder was as follows:

COST OF BINDER.

<i>Materials:</i>	Per box (9 cu. ft.)
0.385 cu. yds. stone at \$1.45.....	\$0.558
0.46 gals. flux at 7 $\frac{1}{2}$ cts. per gal.....	0.034
25.5 lbs. asphalt at \$24.80 per ton.....	0.312
Total materials	\$0.904
Supplies (same as for wearing surface).....	\$0.320
Plant charges (same as for wearing surface).....	0.580
Labor (same as for wearing surface).....	4.889
Grand total	\$6.703

Table XV shows the output and cost by months:

Cost of Bitulithic and Asphalt Pavements and Repairs, Toronto.*
Mr. C. H. Rust, City Engineer of Toronto, is authority for the following:

Most of the streets in Toronto are of a uniform width of 66 ft., and the width of the roadway has been fixed as follows: In busi-

**Engineering-Contracting*, Nov. 17, 1909.

TABLE XV.
Brooklyn Asphalt Repair Plant—Monthly Costs, Total Product and Monthly Box Cost.

Month.	Plant Labor.	Street Labor.	Truck- ing.	Product. Boxes.	Labor Cost, Per Box.	Per Cent Street.	Per Cent Plant.	Per Cent Truck- ing.
June	\$ 1,004.37	\$ 303.75	\$ 387.25	331	\$6.57	37	46	17
July	1,114.00	3,129.00	1,066.00	1,201	4.42	53	21	26

* Average.

ness districts, where the traffic is fairly heavy, or where a double line of street car tracks exist, the width between curbs is 42 ft.; on residential streets the rule is to have the streets 34 ft. between curbs, and in a few cases this has been reduced to 18 ft., but the writer is not in favor of this. By reducing the width of these streets to the above dimensions, a considerable saving has been effected to the property owners, and also a very large saving in the general city taxes by reducing the maintenance, street cleaning, watering, etc.

Asphalt pavements have been in use in Toronto for the past 20 years, and have given general satisfaction. The first pavement laid was of Trinidad Pitch Lake, and several streets constructed of this material have been in use 16 or 17 years before the surface required to be renewed. A few years ago California asphalt was introduced and the pavements constructed of it have shown splendid wearing qualities, and may be expected to give as good satisfaction as the earlier pavements. Texas asphalt has only been used in Toronto for the last two years. The analysis, however, shows up as well as that of any other type of asphalt and may be expected to stand the wear and tear of general traffic equally as well as the others.

This class of pavement is easily cleaned, quickly laid and repaired, and at the present prices is the most economical and satisfactory pavement which can be laid.

Formerly two types were used, namely light and heavy, but experience has led to dividing this into three classes, light, medium and heavy. The light calls for 4 ins. of concrete with 2 ins. of asphalt; medium for 5 ins. of concrete, 1 in. binder and 2 ins. surface, the heavy having 6 ins. of concrete, 1 in. binder and 2 ins. of surface. The price at the present time for light asphalt is \$1.45 per sq. yd.; medium, \$1.75 per sq. yd., and heavy, \$2.00 per sq. yd.

In 1907 the city purchased an asphalt plant with a capacity of 1,500 sq. yds. per day of 8 hrs., and since then not only have some streets been constructed, but all the repairs have been made to pavements which are out of guarantee.

The cost of material and wages in paving work are as follows:

Material:

Asphalt, per net ton, f. o. b. Toronto.....	\$21.95
Screened gravel, per cu. yd., delivered on street.....	1.60
Pit gravel, per cu. yd., delivered on street.....	1.05
Sand for asphalt, per cu. yd., at plant.....	.84
Cement, per bbl., carload lots.....	1.29
Crushed limestone, per ton, on cars.....	1.28
Limestone rubble, per ton, on cars.....	1.10
Crushed granite, per ton, on cars.....	1.60
Limestone dust for asphalt mixture, per ton, in bags of 90 lbs., on cars.....	5.60
Granite blocks, per 1,000.....	67.00
Paving blocks (brick), per 1,000.....	24.50
Paving bricks, per 1,000.....	18.00

Wages:

Laborers, per day of 9 hrs.....	\$ 2.00
Pavers, per hr.....	.25 to .27 1/2
Concrete finishers, per hr.....	.25 to .35
Asphalt rakers, per hr.....	.25
Carters (single team), per hr.....	.35
Teamsters (double team), per hr.....	.55 5-9
Roller engineer, per hr.....	.25
Foremen, per day.....	\$3.00 to 4.00

The cost of cement curbs and sidewalks at Toronto is not reprinted here, but may be found in *Engineering-Contracting*, Nov. 17, 1909.

Plant Burden.—The charges for the plant during the year 1909 were as follows:

Sinking Fund on Investment:	
Cost of plant, \$23,522, at 7% (rate for 20 yrs.).....	\$ 2,346.54
Rental of site, one-half of \$1,000.....	500.00
Taxes	309.00
Miscellaneous Services:	
Phone	16.50
Railway siding	40.17
Insurance (fire)	342.00
Depreciation—(a) building, (b) machinery, 5% of \$23,522	1,676.10
Fuel:	
18,000 batches at this year's average cost, .04 cts. for fuel	1,080.00
Heat and light in winter.....	40.00
Management:	
1/4 of salary of chemist.....	300.00
Fixed Charges:	
Foreman	1,014.00
Watchman, summer and winter.....	608.30
Timekeeper	315.00
Engineer	577.50
Roller	255.00
Repairs	500.00

Total\$10,429.11

Note.—At full capacity the plant develops 28,000 batches in the season of 150 days. An estimate of 18,000 batches as safe, which gives a cost of 58 cts. per batch, burden. If binder is used as well as surface, it makes the cost per batch 75 cts. There are 6 sq. yds. of 2-in. surface to the batch, hence the plant burden is nearly 10 cts. per sq. yd. of 2-in. surface coat.

Cost of Repairs.—The following was the cost of resurfacing 8,117 sq. yds. during the month of June, 1909, with a 2-in. surface coat:

Materials:		Per sq. yd.
0.18 batch asphalt mixture, at \$2.12.....	\$0.380	
0.18 batch plant burden (as above), at \$0.53.....	0.104	
0.2 lbs. stone dust, at \$0.30 per cwt.....	0.006	
0.17 lbs. asphalt cement, at \$1.25.....		
0.006 cords wood, at \$5.11.....		
Total materials	\$0.490	
Labor on Street:		
Laying	\$0.082	
Carting	0.044	
Rolling, 0.028 hrs, at \$1.40.....	0.032	
Total labor on street.....	\$0.158	

Miscellaneous Charges:

Office expense	\$0.005
Engineering, 3%	0.020
Tools, 1%	0.007
Total miscellaneous	\$0.032
Grand total	\$0.680

Note that the item "Labor" includes only street labor, and that "asphalt mixture" and "plant burden" includes materials and labor at the plant.

Cost of a Light Asphalt Pavement.—A light asphalt pavement, 18 ft. wide and 544 ft. long, was laid on Broadway. It was begun May 27 and completed June 19, 1909. The 2-in. asphalt surface occupied 950 sq. yds. (after deducting the cement gutter area). The cost was as follows:

	Per sq. yd.
Grading	\$3.359
Concrete Foundation (4-in.)	0.577
Asphalt Surface:	
0.158 batch asphalt mixture, at \$2.70	0.427
Stone dust, asp. cement and wood	0.004
Carting asphalt mixture	0.038
Labor on street	0.017
Rolling, 0.005 hrs., at \$1.40	0.007
Total asphalt surface	\$0.488
Miscellaneous charges	\$0.100
Grand total	\$1.524

The labor on the concrete foundation, exclusive of carting the materials, was only 9 cts. per sq. yd.

Note that the \$2.70 per batch of "asphalt mixture" includes labor at the plant and plant burden, as well as materials.

Cost of Medium Asphalt Pavement.—An asphalt pavement (1,651 sq. yds.) consisting of a 5-in. concrete base, 1-in. binder, and 2-in. surface was laid on Hackville St., at the following cost:

	Per sq. yd.
Grading:	
Labor	\$0.176
Rolling, at \$1.40 per hr.	0.027
Total grading	\$0.203
Concrete Foundation	\$0.686
Asphalt:	
0.095 batch binder, at \$1.99	\$0.182
0.17 batch asphalt top, at \$2.70	0.450
Stone dust, cement and wood	0.005
Carting	0.037
Labor on street	0.043
Rolling, 0.011 hrs., at \$1.40	0.015
Total asphalt	\$0.722
Miscellaneous	\$0.090
Grand total	\$1.610

The labor on the concrete cost 8 cts. per sq. yd., exclusive of carting.

Cost of Bitulithic Pavement.—On Alhambra Ave., for a distance

of 104 ft., a bitullithic pavement was laid on 4-in. concrete, 719 sq. yds., at the following cost:

	Per sq. yd.
Grading	\$0.252
Concrete Foundation	0.592
Bitullithic Surface:	
Bitullithic materials	\$1.150
Carting	0.093
Labor on street	0.050
Rolling	0.015
Total bitullithic	\$1.308
Miscellaneous Charges	\$0.170
Grand total	\$2.322

Cost of Repairs to Asphalt Pavements, Syracuse, N. Y.—Valuable data on the amount and cost of repairs of asphalt pavements at Syracuse, N. Y., are given in his annual report by City Engineer H. C. Allen. In addition to the data on life and cost, the report presents a plan, which will interest city engineers, for determining when repairs should cease and the pavement be resurfaced. We quote Mr. Allen's report as follows:

The first asphalt pavements in Syracuse, N. Y., were laid in 1889, 20 years ago. Since that time more or less of this kind of pavement has been laid each year, excepting 1891 and 1892, until at present there are about 625,000 sq. yds., outside of the railroad strip and exclusive of asphaltina. In 1902, the Department of Public Works commenced to repair systematically all asphalt pavements out of guarantee and to make a record of the amount of work done and its cost.

Following is a table showing the total number of square yards of asphalt pavement out of guarantee, and the total cost of repairs each year from 1902 to 1908, both inclusive.

Year.	Total Sq. Yds.	Repairs Sq. Yds.	Total Cost.
1902	154,498	1,414	\$ 2,656.40
1903	241,126	2,710	4,586.46
1904	381,180	5,617	9,628.87
1905	396,814	9,308	13,275.43
1906	450,427	14,858	19,447.45
1907	467,162	17,574	24,092.24
1908	494,891	17,821	24,028.08
Totals	69,402		\$97,714.86

The total amount of asphalt pavement required was 69,402 sq. yds., and the cost \$97,714.86, or \$1.41 per sq. yd. of patching. Besides this, there has been a large amount of asphaltina pavement repaired. The laying of asphaltina ceased in 1899 and it has always been kept in repair with asphalt.

During the past two or three years it has been observed that the older asphalt pavements, those laid in 1895 and previous thereto, were fast reaching a condition impracticable to repair, and a time when a new surface must be laid. It was also noticeable that the

*Engineering-Contracting, Mar. 3, 1909.

greater part of the cost of repairs was upon these old pavements. Because of these observed facts, and the constantly increasing annual charge for repairs, a study and analysis of the records were undertaken with a view to recommending a policy on the part of the Department of Public Works with reference to the maintenance of this class of pavements. According to the provisions of the Charter, the cost of paving streets has been paid by the owners of abutting property and, after the expiration of the guaranty period, the Department of Public Works has made the necessary repairs. The analysis above referred to show that the cost per square yard per year for repairs to asphalt increases in an increasing ratio. This ratio has been estimated from experience with the pavements in this city as follows:

Year of the Pavement Life.	Cost Per Sq. Yd. Per Yr. at \$1.41 Per Sq. Yd.	Total Cost to Date Each Yr. Sq. Yd.
6th	\$0.003	\$0.003
7th	.011	.014
8th	.014	.028
9th	.028	.056
10th	.035	.091
11th	.056	.147
12th	.085	.232
13th	.127	.359
14th	.169	.528

It is apparent from these figures as well as from the contemplation of the increasing actual cost from year to year, that the repairs to asphalt pavements by the Department of Public Works can not go on indefinitely without involving the resurfacing of entire pavements.

The Charter provides that the resurfacing of street pavements shall be done at the expense of the owners of abutting property, and the problem here to be solved is the determination of the time at which the Department of Public Works shall cease making repairs, and leave the pavement to be resurfaced in the manner provided by law. Several suggestions have been made, one that a pavement having once been laid, the city shall keep it in repair for a certain period of years, say, until it is 15 years old; another that a pavement shall be kept in repair by the city until a certain percentage of its area shall have been repaired.

Objection is found to the first proposition in that the lives of pavements vary with their location and the volume of traffic to which they are subjected. Some of the asphalt pavements are found to have had as low as 1 per cent of the total surface repaired and to be still in fair condition at the end of 12 years, while others not so favorably located and sustaining heavy traffic have had more than 50 per cent of the total surface repaired in the same period, and are not capable of further repairs. It is evident that a hard and fast rule that all asphalt pavements must be resurfaced at the end of 15 years of life will not operate in an equitable and consistent manner, for the reason that in some cases the condition of the pavement, due principally to its use, will require resurfacing at an earlier period, and in others the rule will require the destruc-

tion and replacement of a pavement which still has in it the ability to render service for a longer period.

The proposition that the city keep an asphalt pavement in repair until such a time as a certain percentage of its total area has been repaired seems to meet the requirements of the situation in a more practical and equitable manner.

The study of the information contained in the record of repairs shows that after the tenth year of life, the amount of repairs per square yard per year increases at a much more rapid rate than in previous years. The results obtained by taking the mean or average of the quantity of repairs to pavements which have reached the age considered is as follows:

Year.	Amount of Repairs.	Sq. Yds.
11th Year—Per Sq. Yd., Per Year:.....		.04
12th Year—Per Sq. Yd., Per Year:.....		.06
13th Year—Per Sq. Yd., Per Year:.....		.09
14th Year—Per Sq. Yd., Per Year:.....		.12
Total repairs		0.31
Average from 6th to 10th year inclusive.....		0.065
Total for 14 years		0.275

It is also to be observed that in the majority of pavements the general condition at the time repairs to the extent of 27½ per cent have been made is such as to render further repairs impracticable, and resurfacing necessary.

Taking the average of all pavements of this kind, it is found that at the end of the 14 years of life the percentage of 27½ per cent of the total area has been repaired, the extremes being such streets as North and South Salina, which reach the limit in 11 years, and others such as Davis and Fitch streets which have not required 5 per cent repairs in 12 or 13 years.

It is therefore recommended that it be the policy of the Department of Public Works to keep up the repairs to asphalt pavements until such time as the total repairs thereon have reached 27½ per cent of the total area; that having made repairs to that extent upon any pavement it be abandoned for further repairs, and reported to the Common Council as a proper object for resurfacing. It should be noted in connection with this discussion and the general one of the participation by the city at large in the cost of pavements, that by paying the cost of repairs until the time the percentage of total surface above commended has been reached, the city at large participates in the cost of the pavement during the period of its life to the extent of about 53 cts. per square yard or about 30 per cent of the total cost of the perishable portion of the pavement.

[For a correct mathematical discussion of problems of this nature, consult Section I of this book.]

If it is thought to be advisable that the general scheme of paving assessment now in force should be changed by Charter amendment, so that the city at large is made to participate in a portion of the original cost of a pavement, it is suggested that it would be an equitable arrangement in making such assessments to consider that

the streets crossed by any proposed pavement are city property fronting the improvement, and to charge the cost of the pavement to this property at the same rate per foot front as other property along the line is called upon to pay.

Cost of Repairs and Life of Asphalt, Washington, D. C.—Capt. H. C. Newcomer gives the following: On July 1, 1903, there were 2,886,786 sq. yds. of sheet asphalt pavements, on 2,425,782 sq. yds. of which the 5 yr. guarantee had expired. The following is the number of sq. yds. of given age above 5 yrs.:

Age, Years.	Sq. Yds.	Age, Years.	Sq. Yds.
5	97,642	19	60,967
6	99,967	20	108,385
7	81,497	21	95,762
8	109,128	22	106,439
9	105,693	23	126,657
10	101,296	24	66,349
11	130,745	25	35,417
12	209,832	26	21,869
13	202,134	27	15,041
14	165,746	28	30,682
15	59,668	29	1,643
16	97,607	30	23,264
17	70,841	31	7,330
18	45,154
Total		2,277,144	

The average age of the above is 14.3 years. The average age of the areas patched during the fiscal year ending July 1, 1903, was 21 years. The patching is done by contract, and is not paid for by the sq. yd., but by the cubic foot of mixed materials measured in the cart, the price being as follows:

	Per cu. ft.
Asphalt surface	\$0.49
Asphalt binder	0.25

The standard pavement has a 6-in. concrete base, a 1½-in. binder course and a 1½-in. wearing surface—total 3 ins. of asphalt measured after rolling.

The contract price for a standard asphalt pavement is \$1.59 per sq. yd., the pavement having a 6-in. base (1 part Portland cement, 4 parts sand, 5 parts gravel and 5 parts broken stone), on which is laid 2 ins. of binder and 2½ ins. of asphalt surface, both measured before compression.

The cost of repairs during the year of 1903 was 2.8 cts. per sq. yd. for pavement of all ages, being distributed thus:

Age of Pavements, Years.	Cost Repairs Per Sq. Yd.
5 to 10	1.65 cts.
10 to 15	2.37 cts.
15 to 20	2.78 cts.
20 to 25	2.8 cts.

— This relates only to patching and does not include any entire renewals of worn out pavements.

Cost of Repairing Asphalt Pavement in Various American Cities.*—The committee appointed by the Municipal Engineers of the City of New York to investigate the cost of repairing asphalt pavement has submitted a report of their work, from which we take the following data. A blank prepared by the committee was sent to 30 of the leading cities in the country which have the largest amount of asphalt pavements, with the request that it be filled out in detail. The object was not only to ascertain the actual cost and method of repairing asphalt pavements, but if possible to determine the cost of repairs according to the age of the pavements. Only eight of the cities replying have kept their records in such shape that this could be obtained and the results are embodied in the accompanying table. The figures in Table XVI are all for the year 1905 except Washington, which is for the year ending June 30, 1905. Although not being able to furnish just what was desired, the following cities gave information regarding their methods:

In Philadelphia there are about 35 miles of asphalt out of guarantee and it is stated they all required resurfacing entire. The prices for resurfacing in patches of 100 sq. yds. or less for 1904 are \$1.19 per sq. yd., patches between 100 and 500 sq. yds. \$1.17 per sq. yd., for surfaces from 500 to 1,000 sq. yds., \$1.11 per sq. yd., for over 1,000 sq. yds. \$1.07 per sq. yd. It is said the amount expended per year depended upon the annual appropriation rather than the need of the streets.

In Minneapolis the area repaired last year was wholly in streets under guarantee where the contractor had failed to live up to his agreement. They were made at a cost of \$1.65 per sq. yd. The total yardage laid under this agreement was 4,525 sq. yds., but no statement was made as to the total area of the streets as repaired.

In Omaha the repairs are made by a municipal asphalt plant, and while no statement was made of the cost by the age of the pavements, the total of 8.8% of the entire yardage repaired was re-laid. This would mean at a cost of 82 cts. per sq. yd., an average of 4% cts. over the entire area.

In Kansas City the method of repairs is such that the following quotation is made from a letter of the Engineer:

"We have repaired since 1903, when the first repairing of asphalt pavements out of maintenance was begun, 41 miles of streets, amounting to 88,000 sq. yds., costing \$124,277.65. The cost of this work has been \$1.50 per square yard until within the last year, when the Economic Asphalt Repair Co. came into the field with their Surface Heater. Since then the price has been cut to 90 cts. per square yard. Previous to this time all repairing work was done by the Barber Asphalt Paving Co., and the method used was to cut out all worn asphalt and replace by new. This latter method was very unsatisfactory, leaving the street in a lumpy condition, and in a short while after this work was done a bad place or hole was

**Engineering-Contracting*, Sept. 19, 1906.

likely to develop alongside the place repaired. It is also very difficult under this method to get a good joint. These repair contracts are for two years—they agreeing to keep the street in condition during the two years of their contract and tax bills being issued for the work done on the street at the middle and end of the period of their contract. This has resulted in the work being in a state of continual repair, tax bills being issued at the end of each year, at the end of the period of the contract the street being in a little better condition than when started."

In New York City, Borough of Manhattan, it is reported, in 1904, 265,000 sq. yds. were maintained at a cost of \$291,167.38, or practically an average of 76 cts. per sq. yd.; in 1905, 460,882 sq. yds., at a cost of \$161,800.90, or an average of 34 cts. per sq. yd.; in 1906 there will be maintained 760,091 sq. yds., at an estimated cost of \$216,225, or 28½ cts. per sq. yd. The figures of Manhattan are very much more than for any other city. This is probably due, it is considered, to the heavy traffic of the Manhattan streets and the fact that many streets have been paved with asphalt where that material does not make an economic pavement.

[I do not concur with this conclusion at all. The City of New York is one of the most extravagant cities in the world, as well as one that has suffered most from "graft."]

Specific Gravity of Bitulithic and Asphalt Pavements.—Mr. J. W. Howard states that the specific gravity of a sample of bitulithic pavement in Baltimore was 2.69, as compared with 2.98, which was the specific gravity of the broken stone used in its construction, the pavement being only 9% less dense than the stone. He states that asphalt pavements have a specific gravity of 1.90 to 2.24, as compared with 2.60 or 2.70, which is the density of the sand and limestone dust used in their construction, indicating that the pavement averages about 20% less dense than the minerals of which it is made.

Cost of Asphalt Cross Walks.—Mr. H. B. R. Craig gives the data upon which the following is based:

In Kingston, Canada, the crossing of macadam streets are made of asphalt, which has been found to have a life of 10 to 20 years. A small plant, costing only \$100, is used. It consists of a 40-gal. asphalt boiler, a sand heater (100 sq. ft. of surface), and a mixing board of the same size. The sand heater is a ½-in. sheet iron plate resting on four brick walls 2 ft. high and 1 ft. thick, enclosing an oven. The fuel (wood) is fed through a hole in the wall.

The following is the gang:

	Per day.
3 men heating asphalt and sand and mixing, at \$1.50.....	\$ 4.50
1 cart hauling to the street.....	2.25
3 men laying and finishing the asphalt surface.....	3.00
Total, 300 sq. ft., at 3.25 cts.....	\$ 9.75
2 men preparing the foundation, at \$1.50.....	3.00
Grand total, 300 sq. ft., at 4.25 cts.....	\$12.75

The following was the cost of 15,000 sq. ft. of asphalt crossings laid in 1905:

	Per sq. ft.
<i>Materials:</i>	Cts.
Stone	0.267
Asphalt, at 1.57 cts. per lb.....	3.690
Cement, at \$1.70 per bbl.....	0.080
Tarred gravel, at 75 cts. per cu. yd.....	0.510
Sand, at 90 cts. per cu. yd.....	0.530
Fuel (very cheap).....	0.110
Hardware	0.015
Total materials	5.302
<i>Labor:</i>	
Boiling asphalt, heating sand, etc.....	1.250
Carting	1.088
Laying and finishing surface.....	0.917
Preparing foundation	1.020
Total labor	4.275
Grand total	9.577

The fuel was old wood and its cost was merely the cost of hauling it.

The method of construction is as follows: The macadam is shaped to the desired cross-section, and a load or two of tarred gravel is spread across the street. The asphalt mixture is laid on this foundation to a thickness of 2 ins. It is well tamped along the edges and rolled with a 2-man roller. The tamper and roller must be oiled to prevent the mixture from adhering. A thin coating of cement is sprinkled over the surface and wetted down, about 1 lb. of cement for every 10 sq. ft.

The surface mixture is made by heating 270 lbs. of Acme asphalt to 300° F. and maintaining that temperature for 2 hrs., constantly stirring. Twenty bushels of medium coarse sand (screened through $\frac{1}{2}$ -in. screen) are heated to drive off moisture. The asphalt and sand are mixed by hand on a mixing board.

Asphalt walks are similarly constructed on a base of 4 ins. of tarred gravel laid on rammed cinders.

Cost of Mixing Concrete Base By Hand.—The ordinary labor cost of concrete foundations is 0.4 to 0.5 of a 10-hr. day's wages per cubic yard of concrete, although occasionally it may be as low as 0.3 of a day where two mixing gangs are worked side by side under separate foremen, and under an exacting contractor. In such a case, the rivalry between the two mixing gangs where the progress of the work can be seen at a glance, as in laying pavement foundations, will insure a saving of at least 25% in the labor item. The following, taken from my note-books and time-books, indicates the ordinary cost of concrete mixing and laying:

Case 1. Laying 6-in. pavement foundation. Stone delivered and dumped upon 2-in. plank laid to receive it. If dumped directly upon the ground it costs half as much again to shovel it up. Sand and stone were dumped along the street, so that the haul in wheelbarrows to mixing board was about 40 ft. Two gangs of men worked

under separate foremen, and each gang averaged 4.5 cu. yds. concrete per hour.

The labor cost was as follows for 45 cu. yds. per gang:

	Per day.	Per cu. yd.
4 men filling barrows with stone and sand ready for the mixers, wages 15 cts. per hr.....	\$ 6.00	\$0.13
10 men, wheeling, mixing and shoveling to place (2 or 4 steps), wages 15 cts. per hr.....	15.00	0.33
2 men ramming, wages 15 cts. per hr.....	3.00	0.07
1 foreman at 30 cts. per hr. and 1 water boy, 5 cts.	3.50	0.08
Total	\$27.50	\$0.61

Case II. Sometimes it is desirable to know every minute detail of cost, for which purpose I give the following:

	—Per cu. yd.—	
	Day's labor.	Cost.
2 men loading stones into barrows.....	.06	\$0.09
1 man loading sand into barrows.....	.03	0.03
2 men ramming04	0.06
1 foreman and 1 water boy equivalent to.....	.035	0.05
9 men { wheeling sand and cement to mix. board	.02	0.03
{ wheeling stone to mixing board.....	.026	0.04
{ mixing mortar013	0.02
{ mixing stone and mortar.....	.049	0.07
{ placing concrete (walking 15 ft.).....	.072	0.11
Total335	\$0.50

In one respect this is not a perfectly fair example (although it represents ordinary practice), for the mortar was only turned over once in mixing instead of three times, and the stone was turned only twice instead of three or four times. Water was used in great abundance, and by its puddling action probably secured a very fair mixture of cement and sand, and in that way secured a better mixture than would be expected from the small amount of labor expended in actual mixing. About 9 cts. more per cu. yd. spent in mixing would have secured a perfect concrete without trusting to the water.

Case III. Two gangs (34 men) working under separate foremen averaged 400 sq. yds., or 100 cu. yds. of concrete per 10-hr. day for a season. This is equivalent to 3 cu. yds. per man per day. The stone and sand were wheeled to the mixing board in barrows, mixed and shoveled to place. Each gang was organized as follows:

	Per day.	Per cu. yd.
4 men loading barrows	\$ 6.00	\$0.13
9 men mixing and placing.....	13.50	0.27
2 men tamping	3.00	0.06
1 foreman	2.50	0.05
Total	\$25.00	\$0.50

These men worked with great rapidity. The above cost of 50 cts. per cu. yd. is about as low as any contractor can reasonably expect to mix and place concrete by hand in pavement work.

Case IV. Two gangs of men, 34 in all, working side by side on

separate mixing boards, averaged 720 sq. yds., or 120 cu. yds., per 10-hr. day. Each gang was organized as follows:

	Per day.	Per cu. yd.
6 men loading and wheeling.....	\$ 9.00	\$0.15
3 men mixing and placing.....	12.00	0.20
2 men tamping	3.00	0.05
1 foreman	3.00	0.05
Total	\$27.00	\$0.45

Instead of shoveling the concrete from the mixing board into place, the mixers loaded it into barrows and wheeled it to place. The men worked with great rapidity.

Case V. Mr. Alfred F. Harley is authority for the following: In laying concrete foundations for street pavement in New Orleans, a day's work, in running three mixing boards, covering the full width of the street, averaged 900 sq. yds., 6 ins. thick, or 150 cu. yds. with a gang of 40 men. With wages assumed to be 15cts. per hr. the labor cost was:

	Cts. per cu. yd.
6 men wheeling broken stone.....	6
3 men wheeling sand	3
1 man wheeling cement	1
2 men opening cement	2
7 men dry mixing	7
8 men taking concrete off.....	8
3 men tamping	3
8 men grading concrete	8
1 man attending run planks.....	1
3 water boys	1
2 extra men and 1 foreman.....	4
Total labor cost.....	39 cts.

Case VI. The following cost of a concrete base for pavements at Toronto has been abstracted from a report (1892) of the City Engineer, Mr. Granville C. Cunningham. The concrete was 1:2½:7½ Portland; 2,430 cu. yds. were laid, the thickness being 6 ins.; at the following cost per cu. yd.:

0.77 bbl. cement, at \$2.78.....	\$2.14
0.76 cu. yd. stone, at \$1.91.....	1.45
0.27 cu. yd. sand and gravel, at \$0.80.....	0.22
Labor (15 cts. per hour).....	1.03
Total	\$4.84

Judging by the low percentage of stone in so lean a mixture as the above, the concrete was not fully 6 ins. thick as assumed by Mr. Cunningham. Note that the labor cost was 1½ to 2 times what it would have been under a good contractor.

It is also noteworthy that Portland cement was used. Until quite recently natural cement has been used almost exclusively in pavement foundations in America. A natural cement concrete is usually made 1:2:5, the cement being measured loose, so that about 1.15 bbls. of cement are required per cubic yard of concrete. A sufficiently good Portland cement concrete can be made with ¾ bbl. cement per cubic yard; and, if the mixing is well done in a mechanical mixer, it is safe to make concrete for pavement founda-

ions 6 ins. thick using not more than $\frac{1}{2}$ bbl. of Portland cement per cubic yard.

Case VII Mr. Charles Apple gives the following data on the cost of a 6-in. concrete foundation for a brick pavement at Champaign, Ill. The concrete was 1:3:3, natural cement, mixed by hand. The material was brought to the steel mixing plate from piles 20 to 60 ft. away.

	Cost per cu. yd.
1.2 bbls. cement, at \$0.50.....	\$0.600
0.6 cu. yd. sand and gravel, at \$1.....	0.600
0.6 cu. yd. broken stone, at \$1.40.....	0.840
6 men turning with shovels, at \$2.....	0.080
4 men throwing into place, at \$2.....	0.053
2 men handling cement, at \$1.75.....	0.023
1 man wetting with hose, at \$1.75.....	0.012
2 men tamping, at \$1.75.....	0.023
1 man leveling, at \$1.75.....	0.012
6 men wheeling stone, at \$1.75.....	0.070
4 men wheeling gravel, at \$1.75.....	0.047
1 foreman, at \$4.....	0.027
Total per cu. yd.....	\$2.387

The cost of mixing and placing this concrete was only 35 cts. per cu. yd., a gang of 26 men and 1 foreman placing 150 cu. yds., or 900 sq. yds., per day. I do not believe these figures of Mr. Apple to be trustworthy, for reasons given on page 360.

Cost of Machine Mixing and Wagon Hauling.—Mr. G. D. Fisher, Asst. Engr., The Laclede Gas Light Co., St. Louis, has given the following data on the mixing, delivering and placing of Portland cement concrete for a pavement base 6 ins. thick.

The gravel was dumped from wagons into a large hopper, raised by a bucket elevator into bins, and drawn off through gates into receiving hoppers on the charging platform where the cement was added. The receiving hoppers discharged into the mixers, which discharged the mixed concrete into a loading car that dumped into wagons, which delivered it on the street where wanted. The longest haul in wagons was 30 mins., but careful tests showed that the concrete had hardened well. The wagons were patent dump wagons of the drop-bottom type.

Mr. Fisher says:

"You may consider the following figures a fair average of the plant referred to, working to its capacity. To these amounts, however, must be added the interest on the investment, the cost of wrecking the plant and the depreciation of the same, superintendence, and the pay roll that must be maintained in wet weather. I am assuming the street as already brought to grade and rolled.

"With labor at \$1.75 per day of 10 hrs., teams at \$4, engineer and foremen at \$3, and engine at \$5 per day, concrete mixed and put in place by the above method costs:

	Per cu. yd.
To mix	\$0.12 to \$0.15
To deliver to street.....	0.10 to 0.14
To spread and tamp in place.....	0.08 to 0.11
Total	\$0.30 to \$0.40

the concrete approached the mixer, less hauling was required, and finally only 2 carts were used.

The Briggs cart is provided with an ingenious dumping device that is operated by the driver, who does not leave the horse's head to dump the cart. As is customary with all one-horse carts on short haul work, the driver leads the horse. The cart dumps from the bottom and spreads the load in a layer about 8 or 9 ins. thick, so that no greater amount of spreading with shovels is necessary than where the concrete is delivered in wheelbarrows. Another feature about the cart that is worthy of mention is the fact that no appreciable amount of the material leaks out, even when the concrete is mixed very wet. It takes about 20 seconds for a cart to back up and get its load and about 5 seconds to dump and spread the load.

On another job where wheelbarrows were used for conveying the concrete, the gang was organized as follows:

- 8 men loading and wheeling gravel in barrows.
- 2 men assisting in loading gravel into barrows.
- 1 man dumping barrows into hopper.
- 3 men loading and wheeling sand.
- 1 man dumping barrows into hopper.
- 7 men wheeling concrete in barrows.
- 3 men spreading concrete.
- 2 men tamping concrete.
- 1 man opening cement and filling buckets.
- 1 man pouring cement into hopper.
- 1 man operating mixer.
- 1 man shovelling up concrete spilled at outlet of mixer in loading barrows.
- 1 engineman.

32 Total.

In dumping the wheelbarrows into the hopper, one man assisted the barrow men at each of the two side hoppers. The wheelbarrow loads of concrete were very small, probably not more than 1 cu. ft. and were wheeled only a short distance over the dirt. The mixer was moved forward at frequent intervals, the stock piles of sand and gravel being continuous piles dumped in advance along the street, sand on one side, gravel on the other side of the street.

Portland cement concrete was used in the proportion of 1:3:6.

The average day's output of this gang was 150 cu. yds., or 900 sq. yds., in 8 hrs.; but on the best day's work the output was 200 cu. yds., or 1,200 sq. yds., in 8 hrs., which is a remarkable record for 32 men and a mixer working only 8 hrs.

When one remembers that an excellent day's work is 8 cu. yds. of concrete per man, where no mixer is used, and that 2 to 2½ cu. yds. is a more common record for hand work on streets, we realize that concrete mixers are bound to become universally used on street work in the very near future, for a mixer practically doubles the output of every man, if the work is properly handled with a mixer adapted to the purpose.

Cost of Concrete Pavement, Windsor, Ont.*—Concrete pavement

**Engineering-Contracting*, Nov. 20, 1907.

is constructed in all essential respects like cement sidewalk. The subsoil is crowned and rolled hard, then drains are placed under the curbs; if necessary to secure good drainage a subbase of gravel, cinders or broken stone 4 to 8 ins. thick is laid and compacted by rolling. The foundation being thus prepared a base of concrete 4 to 5 ins. thick is laid and on this a wearing surface 2 to 3 ins. thick.

In constructing concrete pavement at Windsor, Ont., the street is first excavated to the proper grade and crown and rolled with a 15-ton roller. The drains are then placed directly under the curb line and a 6 x 16-in. curb is constructed, using 1:2:4 concrete faced with 1:2 mortar. Including the 3-in. tile drain this curb costs the city by contract 38 cts. per lin. ft. The pavement is then constructed between finished curbs.

The fine profile of the subgrade is obtained by stretching strings from curb to curb, measuring down the required depth and trimming off the excess material. The concrete base is then laid 4 ins. thick. A 1:3:7 Portland cement concrete is used, the broken stone ranging from $\frac{1}{4}$ in. to 3 ins. in size, and it is well tamped. This concrete is mixed by hand and as each batch is placed the wearing surface is put on and finished. The two layers are placed within 10 mins. of each other, the purpose being to secure a monolithic or one-piece slab. The top layer consists of 2 ins. of 1:2:4 Portland cement and screened gravel, $\frac{1}{4}$ in. to 1 in., concrete. This layer is put on rather wet, floated with a wooden float and troweled with a steel trowel while still wet. Some 20,500 sq. yds. of this construction have been used and cost the city by contract:

	Per sq. yd.
Bottom 4-in. layer 1:3:7 concrete.....	\$0.57
Top 2-in. layer 1:2:4 concrete.....	0.32
Excavation	0.10
Total	\$0.99

This construction was varied on other streets for the purpose of experiment. In one case a 4-in. base of 1:3:7 stone concrete was covered with 2 ins. of 1:2:2 gravel concrete. In other cases the construction was: 4-in. base of 1:3:7 stone concrete; $1\frac{1}{2}$ -in. middle layer of 1:2:4 gravel concrete and $\frac{1}{2}$ -in. top layer of 1:2 sand mortar. All these constructions have been satisfactory; the pavement is not slippery. The cost to the city by contract for the three-layer construction has in two cases been as follows:

Church St., 8,000 sq. yds.:	Per sq. yd.
4-in. base 1:3:7 concrete.....	\$0.57
$1\frac{1}{2}$ -in. 1:2:4 and $\frac{1}{2}$ -in. 1:2 mixture.....	0.32
Excavation	0.10
Total	\$0.99
Albert and Wyandotte Sts., 400 sq. yds.:	Per sq. yd.
4-in. base 1:3:7 concrete.....	\$0.84
$1\frac{1}{2}$ -in. 1:2:4 and $\frac{1}{2}$ -in. 1:2 mixture.....	0.39
Excavation	0.10
Total	\$1.15

The cost of materials and rates of wages were about as follows:

Portland cement f. o. b. cars Windsor, per bbl.....	\$2.05
River sand, excellent quality, per cu. yd.....	1.15
River gravel, screened, per cu. yd.....	1.25
Crushed limestone, $\frac{1}{4}$ to $\frac{3}{4}$ in., per ton.....	1.15
Labor, per day.....	\$1.75 to 2.00

At these prevailing prices the contractor got a fair profit at the contract price of \$1.15; at 99 cts., any profit is questionable, according to City Engineer George S. Hanes, who gives us the above records. Expansion joints are located from 20 to 30 ft. apart and are filled with tar. Mr. Hanes writes that a large amount of this pavement will be built during 1908.

Cost of Excavating Concrete Base (Street Railway) and Laying New Concrete.—In the spring of 1906 the United Railways Company, of St. Louis, Mo., undertook the reconstruction of six miles of its tracks on Olive St., in St. Louis. The reconstruction of these tracks is described by Mr. Richard McCulloch as follows:

Excavating Old Concrete Foundation.—In order to build the track it was necessary to make an excavation 21 in. in depth in a concrete which had been setting for 18 years, and which experience in whatever excavations had been made had shown to be extremely hard. The method adopted for excavating the concrete was by blasting with small charges of dynamite, the object being to make these charges strong enough to shatter the concrete so that it could be taken out in large pieces, but not heavy enough to do other damage. Holes were drilled 7 to 8 in. deep in the concrete, 16 in. from the center of each rail, and 24 in. apart, four holes coming between each pair of yokes. (The Olive St. line was at one time a cable road, a double cable track having been built for a distance of $2\frac{1}{2}$ miles. In this construction a girder rail was laid on cast-iron yokes weighing 300 lbs. each, set in concrete 4 ft. apart. These yokes were 48 in. in depth and inclosed a conduit for the cable 18 in. in depth. In subsequent reconstructions when the road was converted into an electric line these yokes were left in place and the electric cars operated over the cable roadbed without change.) The hole was so located that the bottom of the hole was a little below the center of gravity of the section of concrete to be removed.

For drilling the holes there were used No. 2 Little Jap drills made by the Ingersoll-Rand Co., operated by compressed air at 90 lbs. pressure. This tool drills a 1.25-in. hole. A dry hole was drilled, the exhaust air from the hollow drill steel blowing the dust from the hole and keeping it clean. Common labor was used to run the drills and very little mechanical trouble was experienced. Three cars were fitted up, one for each gang, each car being equipped with a motor-driven air compressor, water for cooling the compressors being obtained from the fire plugs along the route. The air compressors were taken temporarily from those in use in the repair shops, no special machines being bought for the purpose. Electricity for

* *Engineering-Contracting*, Dec. 5, 1906.

operating the air compressor motors was taken from the trolley wire over the tracks. The car was moved along as the holes were drilled, air being conveyed from the car to the drills through a flexible hose. Two drills were operated normally from each car. One of the air compressors was exceptionally large and at times operated four drills.

The total number of holes drilled in the reconstruction of the track was 31,000. The total feet of hole drilled was 20,700 ft. The following figures give the average performance of the best one of the drilling outfits, which operated from two to three drills:

Depth of hole.....	8 ins.
Number of holes per hour per drill.....	30
Feet of hole drilled per hour per drill.....	20.2
Labor cost per foot of hole drilled.....	\$0.027
Labor cost of drilling per cu. yd. blasted.....	\$0.085
Drilling cost per lin. ft. of track.....	\$0.017
Drilling cost per mile of track.....	\$89.76

In these figures there is no charge for electric power or for depreciation of machinery.

For blasting, a 0.1-lb. charge of 40 per cent dynamite was used in each hole. A fulminating cap was used to explode the charge, and 12 holes were shot at one time by an electric firing machine. The dynamite was furnished from the factory in 0.1-lb. packages, and all the preparation necessary on the work was to insert the fulminating cap in the dynamite, tamp the charge into the hole and connect wires to the firing machine. In order to prevent any damage being done by flying rocks at the time of the explosion, each blasting gang was supplied with a cover car, which was merely a flat car with a heavy bottom and side boards. When a charge was to be fired, this car was run over the 12 holes and the side boards let down, so that the charge was entirely covered. This work was remarkably free from accidents. There were no personal accident claims whatever, and the total amount paid out for property damages for the whole six miles of construction was \$685. Most of this was for glass broken by the shock of explosion. There was no glass broken by flying particles. The men doing this work, few of whom had ever done blasting before, soon became very expeditious in handling the dynamite, and the work advanced rapidly. The report made by the firing of the 12 holes was no greater than that made by giant firecrackers.

For the drilling and blasting the old rail had been left in place to carry the air compressor car and the cover car. After the blasting, this rail was removed and the concrete excavated to the required depth. In most cases the cable yokes had been broken by the force of the blast. Where these yokes had not been broken, they were knocked out by blows from pieces of rail. The efficacy of the blasting depended largely upon the proper location of the hole. Where the holes had been drilled close to the middle of the concrete block, so that the dynamite charge was exploded a little below the center of gravity of the section, the concrete was well shattered and could be picked out in large pieces. Where the hole had been located too close to either side of the concrete block, however, the

charge would blow out at one side and a large mass of solid concrete would be left intact on the other side. The total estimated quantity of concrete blasted was 8,558 cu. yds., or 0.3 cu. yds. of concrete per lineal foot of track. The cost of the dynamite delivered in 8.1-lb. packages was 13 cts per lb. The exploders cost \$0.0255 each.

The following data represent the average work of the three gangs working on the westbound track between 14th St. and Boyle Ave.:

Cost of dynamite charge per hole.....	\$0.013
Cost of exploder per hole.....	\$0.0255
Four holes blasted in each 4 ft. of track:	
Lin. ft. of track blasted per hour.....	128
Cu. yds. of concrete blasted per hour.....	27.6
Cu. yds. of concrete blasted per lb. of dynamite....	2
Labor cost per cu. yd. blasted.....	\$0.076
Cost dynamite and exploders per cu. yd. blasted...	\$0.192
Cost labor and material per cu. yd. blasted.....	\$0.268
Cost blasting per lin. ft. of track.....	\$0.064
Cost blasting per mile of track.....	\$255.12
Cost drilling and blasting per cu. yd.....	\$0.353
Cost drilling and blasting per lin. ft. of track.....	\$0.071
Cost drilling and blasting per mile of track.....	\$274.88

When the excavation was completed, the ties were placed in the trench, the rail spiked down, the tie rods pulled up to gage and temporary fishplates put on the joints. Work trains were then run on this track and the excavated material hauled away. The excavated material in this job amounted to 11,410 cu. yds., or 0.348 cu. yd. per lineal foot of track. The United Railways Company purchased a sink hole and completely filled it with excavated material. All excavated material and all new material with the exception of the cement used in this work was handled on cars, no teams being used at all. It would have been impossible to do the work in the time occupied had wagons and teams been depended upon.

The ties were of hewn cypress, 8 in. x 8 in., in sections, and 7 ft. long, and were spaced 2 ft. between centers. Tie plates were used under the rail, each alternate tie plate being a brace plate. The rail used weighed 118 lbs. per yard and was furnished in 60-ft. lengths.

Mixing and Placing New Concrete.—After the excavated material had been hauled away and the street cleaned up, the track was lined and surfaced by means of wooden blocks and wedges placed beneath the ties. Concrete was then tamped beneath and around the ties, the concrete being deposited in the track from a concrete mixing machine running on the rails. The concrete used was composed of a mixture by volume of 1 part of Portland cement, 2½ parts of river sand and 6½ parts of crushed limestone rock. The cost (delivered) of the materials composing this concrete was as follows:

Crushed rock.....	\$2.85 per square	{ = \$0.0285 per cu. ft.
Sand	\$2.50 per square	{ = 0.77 per cu. yd.
Portland cement	\$1.70 per barrel	{ = 0.025 per cu. ft.
		{ = 0.675 per cu. yd.
		{ = 0.425 per sack.

For the track work, 7.36 cu. ft., or 0.272 cu. yd., were required per

lineal foot of track, $1\frac{1}{2}$ sacks of cement per lineal foot of track, or 1,450 bbis. of cement per mile of track, were used in this work.

The value of the cement, rock and sand used was \$0.108 per cu. ft. of concrete, or \$2.92 per cu. yd. of concrete.

The material for the concrete was distributed on the street beside the tracks in advance of the machine, the sand being first deposited, then the crushed rock piled on that, and finally the cement sacks emptied on top of this pile. The materials were shoveled from this pile into the concrete mixing machine without any attempt at hand mixing on the street. Great care was taken in the delivery of materials on the street to have exactly the proper quantity of sand, rock and cement, so that there would be enough for the ballasting of the track to the proper height and that none would be left over. Each car was marked with its capacity in cubic feet, and each receiver was furnished with a table by which he could easily estimate the number of lineal feet of track over which the load should be distributed.

The concrete mixing machines were designed and built in the shops of the United Rys. Co. Three machines were used in this work, one for each gang. The machine is composed of a Drake continuous worm mixer, fed by a chain dragging in a cast-iron trough. The trough is 26 ft. long, so that there is room for fourteen men to shovel into it. Water is sprayed into the worm after the materials are mixed dry. This water was obtained from the fire plugs along the route. In the first machine built, the Drake mixer was 8 ft. long. In the two newer machines the mixer was 10 ft. long. Both the conveyor and the mixer were motor driven, current being obtained for this purpose from the trolley wire overhead. Two types of machines were used, one in which the conveyor trough was straight and 45 in. above the rail, and the other in which the conveyor trough was lowered back of the mixer, being 25 in. above the rail. The latter type had the advantage of not requiring such a lift in shoveling, but the trough is so low that a motor truck cannot be placed underneath it. In the high machine the mixer is moved forward by a standard motor truck under the conveyor. In the low machine the mixer is moved by a ratchet and gear on the truck underneath the mixer. A crew of 27 men is required to work each machine, and under average conditions concrete for 80 lin. ft. of single track, amounting to 22 cu. yds., can be discharged per hour. The following figures give the average performance of the three machines in concreting the westbound track from 14th St. to Boyle Ave.:

Number men employed at machine.....	27
Number men shoveling into machine.....	14
Lin. ft. track concreted per hour.....	80.95
Cu. ft. concrete discharged per hour.....	595.79
Cu. yd. concrete discharged per hour.....	22.06
Labor cost concrete per lin. ft. of track.....	\$0.071
Labor cost concrete per cu. yd.....	\$2.26
Cost of materials composing concrete per lin. ft. of track	\$0.791
Cost of materials composing concrete per cu. yd....	\$2.92

Total cost of concrete (labor and material) per lin. ft. of track.....	\$0.862
Total cost of concrete (labor and material) per cu. yd.	\$3.18
Total cost of concrete (labor and material) per mile of single track	\$4,551.36

In these figures there is no charge for electric power or for depreciation.

The section between 14th St. and Boyle Ave. (5.51 miles long) was divided into three sections, and three foremen, with independent gangs, were put on each section. Work was carried on day and night. The Olive St. line is a double-track road, and during construction one track was kept open for traffic in one direction. Cars going in the opposite direction were sent by another route.

The work was begun April 30, 1906, and the cars were turned back on the street, exactly six weeks having elapsed since ground was broken. Of this time two weeks were allowed for the setting of the concrete, so that the entire work, with the exception of paving, was done in four weeks, an average of 1,040 lin. ft. of single track per day. The cost of this 5½ miles of track was about \$170,500. For the entire work, after allowing for scrap material from the old track, the average cost per mile was about \$27,000.

Cost of Excavating an Asphalt Pavement and Its Concrete Base.*
—In relaying a street car track it was necessary to excavate the pavement between the rails, and for two feet outside the rails. The pavement was asphalt 2½ ins. thick laid on a concrete base 8 ins. thick. The concrete was made with natural cement and was consequently by no means as difficult to excavate as it would have been if Portland cement had been used.

In taking up the asphalt between the tracks it was found that the progress depended very much upon the temperature of the day. On cool days when the asphalt was brittle and the men worked rapidly, it was possible for three men to excavate 4,800 sq. ft. between the tracks in 10 hours. This is equivalent to nearly 180 sq. yds. per man per day. Of course, it was not necessary to cut the asphalt loose from the rails on each side, so the work consisted merely in prying up the asphalt with crow bars and breaking it with a sledge. Two men pried the asphalt up, while a third man used the sledge, and cast the pieces aside ready to be hauled away.

During most of the time, however, the asphalt was hot enough not to be brittle, and had to be cut up with a grub ax. In that case two men would pry up the asphalt, using picks, while the third man would cut off a strip 1½ ft. wide and as long as the distance between the tracks. Then he would cut this strip in two pieces with the grub ax. In the meantime the two men with the picks would be prying up some more of the asphalt. These three men worked very deliberately and averaged 1,700 sq. ft. per day. This is

**Engineering-Contracting*, Sept. 19, 1906.

equivalent to 63 sq. yds., or $4\frac{1}{4}$ cu. yds. per man per day. Wages were \$1.76, hence the cost of excavating the asphalt was 2½ cts. per sq. yd., or 40 cts. per cu. yd. This does not include the cost of loading and hauling it away.

In excavating the strip 1 ft. wide outside the rails, it was, of course, necessary to cut through the asphalt along a line parallel with the rail and 1 ft. away. To do this cutting a chisel having a bit 3 ins. wide and provided with a handle, was held by one man while a second man struck it with a sledge. These two men, when working rapidly, would cut 1,200 lin. ft. in 10 hours; hence one man cut 600 lin. ft., thus loosening 600 sq. ft. of asphalt ready to be pried up. A third man would pry up the asphalt with a pick and cut it off in sections, and he averaged 600 sq. ft. a day, working very deliberately. Hence the average output of each of the three men was 200 sq. ft., or 23 sq. yds., per man per day, cut out, pried up, and cast aside. This is equivalent to a little more than $2\frac{1}{4}$ cu. yds. per man per day, and the cost was 76 cts. per cu. yd., or 6½ cts. per sq. yd.

As above stated, the concrete was 9 ins. thick and was made with natural cement. It was loosened with picks, usually without great difficulty, and was shoveled aside ready to be hauled away. Each laborer averaged 3 cu. yds., or 12 sq. yds. per day. Hence the cost was practically 60 cts. per cu. yd., or 15 cts. per sq. yd. To this should be added the cost of loading into wagons, which was 16 cts. per cu. yd., or 4 cts. per sq. yd. The cost of hauling depends upon distance to be hauled, and can be easily estimated for any given conditions.

Amount of Materials Required for Cement Sidewalk Construction.*

— The great majority of cement sidewalks come within the range of 3 ins. to 7 ins. in thickness; the most common base mixtures are 1:2:5 and 1:3:6 and the most common finishing mixtures are 1:1, 1:1½ and 1:2. The accompanying tables have been computed to give by simple arithmetic, the volume of concrete, and the quantities of cement, sand and stone required per 100 sq. ft. of sidewalk, ranging from 3 ins. to 7 ins. thick and constructed of the above named mixtures. Table XVII gives separately the volume of base concrete and of surfacing mortar in 100 sq. ft. of walk of the different thicknesses; Table XVIII gives for each of the thicknesses and mixtures named the amount of cement, sand and stone required per 100 sq. ft.

The tables have been calculated on the assumption that—the cement being measured loose as is usual in sidewalk work—a barrel of cement measures 4.4 cu. ft. For finishing mortar the voids in the sand amount to 45 per cent; for base concrete the voids are assumed to be 40 per cent for sand and 45 per cent for broken stone. On these assumptions according to the theory of proportioning and the tables of mortar given in the section on Concrete, the

**Engineering-Contracting*, Nov. 4, 1902, and Jan. 13, 1903.

TABLE XVII.—SHOWING QUANTITIES OF CEMENT, SAND AND BROKEN STONE REQUIRED FOR 100 SQ. FT. OF SIDE-WALK SEPARATELY FOR RASH AND FOR SURFACE FINISH FOR DIFFERENT PROPORTIONS OF CONCRETE AND DIFFERENT THICKNESSES OF WALK.

6	2.45	0.73	1.57	2.17	0.71	1.78	1.59	0.82	1.64	2	2.38	0.371	2.06	0.494	1.79	0.556					

amount of materials per cubic yard of mortar and of concrete are as follows:

<i>Mortar proportions:</i>		1:1	1:1½	1:2
Barrels of cement.....	2.94	3.34	2.90	
Cubic yards of sand.....	0.6	0.8	0.9	
<i>Concrete proportions:</i>		1:2:5		1:3:6
Barrels cement.....	1.16		0.90	
Cubic yards sand	0.38		0.44	
Cubic yards stone	0.95		0.88	

Table XVIII has been computed from the above quantities and those given in Table XVII; thus for a 3-in. base (Table XVII) 0.93 cu. yd. of concrete is required per 100 sq. ft.; if the base be a 1:2:5 mixture, then the

Cement = 0.93 cu. yd. × 1.16 bbl. = 1.08 bbl.

Sand = 0.93 cu. yd. × 0.38 cu. yd. = 0.35 cu. yd.

Stone = 0.93 cu. yd. × 0.95 cu. yd. = 0.88 cu. yd.

The final results are the quantities given in Table XVIII, and the other quantities given in this table are obtained in a similar manner.

TABLE XVII.—SHOWING VOLUME OF CONCRETE BASE AND MORTAR WEARING SURFACE PER 100 SQ. FT. OF CEMENT WALK OF VARIOUS THICKNESSES.

—Concrete Base.—		—Mortar Wearing Surface.—	
Thickness, ins.	Volume, cu. yds.	Thickness, ins.	Volume, cu. yds.
2½	0.77	¾	0.155
3	0.93	¾	0.232
3½	1.08	1	0.309
4	1.24	1½	0.386
4½	1.39	1½	0.464
5	1.55	1¾	0.541
6	1.87	2	0.618

Note.—100 sq. ft. of walk 1 in. thick has a volume of 0.309 cu. yd. To get the volume in a walk of any thickness, multiply 0.309 by the thickness of the walk in inches, e. g., 0.309 cu. yd. × 6 ins. = 1.87 cu. yd.

Table XVIII is used in estimating as follows:

Problem: Find the amount of cement, sand and stone required for 1,000 ft. of sidewalk, 5 ft. wide; base 4 ins. thick of 1:2:5 concrete; wearing surface 1 in. thick of 1:1½ mortar.

From Table XVIII we have:

Per 100 sq. ft.	Cement, bbls.	Sand, cu. yds.	Stone, cu. yds.
Base, 4 ins.....	1.43	0.47	1.16
Wearing surface 1 in.	1.03	0.247	...
Total per 100 sq. ft.....	2.46	0.717	1.16
	50*	50	50
Total per 5,000 sq. ft.....	123.00	35.850	59.00

*1,000 × 5 = 5,000 ÷ 100 = 50.

Cost of Cement Walks.—The cost of cement walks is commonly estimated in cents per square foot, including the necessary excavation and the cinder or gravel foundation. The excavation usually costs about 13 cts. per cu. yd., and if the earth is loaded into wagons the loading costs another 10 cts. per cu. yd., wages being 15 cts. per hr. The cost of carting depends upon the length of haul, and may be estimated from data given on page 121. If the total

cost of excavation is 27 cts. per cu. yd., and if the excavation is 12 in. deep we have a cost of 1 ct. per sq. ft. for excavation alone. Usually the excavation is not so deep, and often the earth from the excavation can be sold for filling lots.

The base of the walk is often made 3 in. thick, of 1 : 3 : 6 concrete, and the top wearing coat is often made 1 in. thick of 1 : 1½ mortar. The cement is invariably Portland.

Such a walk is frequently laid on a foundation of gravel or cinders 4 in. thick.

And by using the table on page 443, we can estimate the quantity of cement required for any given mixture.

As the average of a number of small jobs, my records show the following costs per sq. ft. of 4-in. walk such as just described:

	Cts. per sq. ft.
Excavating 8 in. deep	0.65
Gravel for 4-in. foundation, at \$1.00 per cu. yd.	1.20
0.018 bbl. cement, at \$2.00	3.60
0.009 cu. yd. broken stone, at \$1.50	1.35
0.008 cu. yd. sand, at \$1.00	0.80
Labor making walk	1.60
Total	3.00

This is 9 cts. per sq. ft. of finished walk. The gangs that built the walk were usually 2 masons at \$2.50 each per 10-hr. day with 2 laborers at \$1.50 each. Such a gang averaged 500 sq. ft. of walk per day.

Cost of Cement Walk.*—The following notes, based on actual experience, relative to the cost of a walk, are taken from a pamphlet prepared by Mr. C. W. Boynton and published by the Universal Portland Cement Co. Experience has shown that a gang of six men can lay between 600 and 800 sq. ft. of walk in a day of 10 hrs. and 700 sq. ft. is considered as a day's work in arriving at the figures given below. This estimate is based on a 6-ft. walk having a 4-in. base, consisting of 1 part cement, 2½ parts sand and 5 parts crushed stone, covered with a ¾-in. top of 1 part cement and 1½ parts sand. The stone ranged in size from ¾-in. to ¾-in. and contained 48% voids. A good grade of lake sand passing a ¾-in. screen was used. The sand contained 36% voids. The mixing was done by hand, and the cost of materials includes delivery on the work. The costs were as follows:

Labor:	
One finisher at \$5 per day	\$ 5.00
Five laborers at \$2 per day	10.00
Total, 700 sq. ft. at 2.14 cts.	\$15.00
Materials:	
Cement, 2.5 bbls. at \$2.00	\$ 5.00
Stone, 1.11 cu. yds. at \$1.50	1.66
Sand, .77 cu. yds. at \$1.0077
Cinders, 2.7 cu. yds. at 50c.	1.35
Total cost materials for 100 sq. ft. at 3.78	
cts.	\$ 3.78
Total labor and materials, per sq. ft., 10.92 cts.	

*Engineering-Contracting, Aug. 26, 1908.

It should be noted that this estimate provides for a walk where an excavation for the sub-base was necessary.

Cost of Cement Walks in Iowa.—Mr. L. L. Bingham sent out letters to a large number of sidewalk contractors in Iowa asking for data of cost. The following was the average cost per square foot as given in the replies:

	Cts. per sq. ft.
Cement, at \$2 per bbl.....	3.8
Sand and gravel	1.6
Labor, at \$2.30 per day (average).....	2.3
Incidentals, estimated	0.7
Total per sq. ft.	8.0

This applies to a walk 4 ins. thick, and includes grading in some cases, while in other cases it does not. Mr. Bingham writes me that in this respect the replies were unsatisfactory. He also says that the average wages paid were \$2.30 per man per day. It will be noted that a barrel of cement makes 55½ sq. ft. of walk, or it takes 1.8 bbls. per 100 sq. ft.

The average contract price for a 4-in. walk was 11½ cts. per sq. ft.

Cost of Cement Walk, San Francisco.—Mr. George P. Wetmore, of the contracting firm of Cushing & Wetmore, San Francisco, gives the following:

The foundations of cement walks in the residence district of San Francisco are 2½ ins. thick, made of 1:2:6 concrete, the stone not exceeding 1 in. in size. The wearing coat is ½ in. thick, made of 1 part cement to 1 part screened beach gravel. The cement is measured loose, 4.7 cu. ft. per bbl. The foundation is usually laid in sections 10 ft. long; the width of sidewalks is usually 15 ft. The top coat is placed immediately, leveled with a straight edge and gone over with trowels till fairly smooth. After the initial set and first troweling, it is left until quite stiff, when it is troweled again and polished—a process called "hard finishing." The hard finish makes the surface less slippery. The surface is then covered with sand, and watered each day for 8 or 10 days. The contract price is 9 to 10 cts. per sq. ft. for a 3-in. walk; 12 to 14 cts. for a 4-in. walk having a wearing coat ¾ to 1 in. thick. A gang of 3 or 4 men averages 150 to 175 sq. ft. per man per day of 9 hrs. Prices and wages are as follows:

Cement, per bbl.	\$2.50
Crushed rock, per cu. yd.....	1.75
Gravel and sand for foundation, per cu. yd.....	1.40
Gravel for top finish, per cu. yd.....	1.75
Finisher wages, best, per hr.....	0.40
Finisher helper, best, per hr.....	0.25
Laborer, best, per hr.....	0.20

Cost of Cement Sidewalks, Toronto, Ont.*—A considerable part of the public improvement work of Toronto, Ont., is done by day labor under the supervision of the city engineer. In the following article is given the actual unit costs of the construction of 4½-in. concrete sidewalks, 4 ft. and 6 ft. wide, built by day labor.

**Engineering-Contracting*, Aug. 29, 1906.

The sidewalks have a 4-in. foundation of coarse gravel or soft coal cinders, thoroughly consolidated by pounding or rolling, upon which is placed a 3½-in. layer of concrete, composed of 1 part Portland cement, 2 parts of clean, sharp, coarse sand, and 5 parts of approved furnace slag, broken stone or screened gravel. The wearing surface is 1 in. thick and is composed of 1 part Portland cement, 1 part of clean, sharp, coarse sand and 3 parts of screened pea gravel, crushed granite, quartzite or suitable hard limestone.

COST OF 6-FT. SIDEWALK.

	Per sq. ft.
Labor	5.59 cts.
0.018 bbla. cement, at \$1.54.....	2.49 cts.
0.027 cu. yds. gravel, at \$0.80.....	2.21 cts.
0.0048 cu. yds. sand, at \$0.80.....	0.37 cts.
Water	0.05 cts.
Total	10.71 cts.

COST OF 4-FT SIDEWALK.

	Per sq. ft.
Labor	6.73 cts.
0.0204 bbla. cement, at \$1.54.....	3.15 cts.
0.0206 cu. yds. gravel, at \$0.80.....	1.65 cts.
0.0049 cu. yds. sand, at \$0.80.....	0.39 cts.
Water	0.07 cts.
Total	11.93 cts.

The rates of wages and the number of men employed were as follows:

1 foreman	\$3.50 per day.
1 finisher ..	0.50 per hour.
1 helper	0.22 per hour.
15 laborers	0.20 per hour.

We are indebted to Mr. C. H. Rust, City Engineer of Toronto, Ont., for the above information.

Note how these labor costs are double what it costs a capable contractor to do the same class of work.

Cost of a Cement Walk, Forbes Hill Reservoir.—Mr. C. M. Saville, M. Am. Soc. C. E., gives the following data relating to 6,250 sq. ft. of cement walk built by contract:

	Per cu. yd.	Per sq. ft.
Stone foundation		
Broken stone for 12-in. foundation.....	\$0.40	\$0.015
Labor placing same, 15 cts. per hr.....	1.50	0.058
Total	\$1.90	\$0.071
Concrete base (4½ in. thick).		
1.22 bbla. cement per cu. yd., at \$1.53..	\$1.87	\$0.026
0.50 cu. yd. sand per cu. yd., at \$1.02..	0.51	0.007
0.84 cu. yd. stone per cu. yd., at \$1.57..	1.32	0.019
Labor (6 laborers and 1 team).....	3.48	0.050
Total (for 90 cu. yds.).....	\$7.18	\$0.102
Top finish (1 in. thick).		
4 bbla. per cu. yd., at \$1.53.....	\$6.12	\$0.019
0.8 cu. yd. sand, at \$1.00.....	0.80	0.002
Lampblack	0.29	0.001
Labor (2 walk masons and 1 helper)...	6.36	0.016
Total	\$13.57	\$0.038
Grand total		\$0.211

This walk was 6 ft. wide laid on a 12-in. foundation of broken stone. On top of this foundation was the concrete base, 5 in. thick in the middle and 4 in. thick at the sides. This base was surfaced with a top granolithic finish about 1 in. thick.

It is difficult to account for the high labor cost (\$1.50) of placing the 12-in. stone foundation except on the supposition that the stones were broken by hand.

The work on the concrete base was unusually expensive, for no apparent reason except inefficiency of the men.

The two masons received \$2.25 each per day, and their helper \$1.50, and they averaged 360 sq. ft. per day, or 60 lin. ft. of walk 6 ft. wide, which is equivalent to 1½ cts. per sq. ft.

Atlas cement was used, and in measuring was assumed to be 3.7 cu. ft. per bbl.

It is perhaps useless to comment on the extravagantly large amount of stone used in the foundation.

Cost of Acid Finish on Cement Walk.*—In making 86,650 sq. ft. of cement walks (25 ft. wide), the South Park Commission of Chicago did the work by day labor (in 1908) at the following cost:

	Per sq. ft. Cts.
Cement, at \$1.35 per bbl.....	3.46
Sand and broken stone.....	4.70
Forms	0.29
Labor	3.70
Superintendence and tools (10% of above).....	1.23
Total	13.47
Grading and filling with cinders.....	4.73
Finishing surface with acid.....	1.67
Grand total	20.17

The cement walk was 5 in. thick (a 4-in. base of 1:2:4 concrete and a 1-in. surface of 1:2½), resting on 12 in. of cinders. In spite of the fact that a machine mixer was used, the labor and superintendence on the cement work cost the very high sum of 4.92 cts. per sq. ft., which did not include the labor on the acid finish nor on the grading and cinders. This furnishes another example of an ill-advised attempt to "save the contractor's profits."

The cost of finishing 29,395 sq. ft. of the surface by acid was as follows:

	Total.	Per sq. ft. Cts.
10,800 lbs. (\$0 carboys) muriatic acid, at 1¼ cts.	\$135 00	0.46
26 deck brushes, at 50 cts.....	13 00	0.06
Labor	290 00	1.00
Add 10% for superintendence.....	44 00	0.15
Total	\$482 00	1.67

*Engineering-Contracting, Dec. 9, 1908.

Cost of Cement Curb and Sidewalks, Gary, Ind.*—Mr. E. M. Schedow gives the following:

The improvement of Madison St. at Gary, Ind., from the south line of the Wabash R. R. to the north line of the Pittsburg, Ft. Wayne & Chicago R. R., a distance of 3,800 ft., has been recently completed. The improvement consisted of brick pavement (see page 364 for cost), concrete curbs 5 ins. x 18 ins., with 5 ft. radii at street intersections and cement sidewalk 5½ ft. wide. The grading was all done during the winter while the ground was frozen and all the material was hauled at that time. These costs do not include grading.

Cost of Placing Curb.—The mixture for curbs was 1:3:5 Portland cement, torpedo sand and broken limestone, with a facing 1½ ins. thick composed of 1:1:5 of Portland cement, sand and granulated granite. The concrete was mixed dry by hand and then mixed wet in a worm screw mixer operated by a gasoline engine. Wooden forms were used.

The labor cost was as follows:

	Total.	Per lin. ft.
Laborers, mixing, 128 days, at \$2.00.....	\$256.00	\$0.0851
Laborers, wheeling and tamping, 127 days, at \$2.....	254.00	0.0348
Finishers, 51 days, at \$5.50.....	280.50	0.0383
Form setters, 80 days, at \$3.....	240.00	0.0330
Total, 7,368 lin. ft.....	\$1,030.50	\$0.1412

Labor Cost of Laying Sidewalks.—The sidewalk was laid with a concrete foundation 3¾ ins. thick of the same proportions as that given for curbs and a wearing surface ¾ in. thick composed of five parts of Portland cement to seven parts of sand. The labor cost was as follows, the same method of mixing the concrete being used as for curbs:

	Total.	Per sq. ft.
Laborers, mixing, 117 days, at \$2.....	\$234.00	\$0.0060
Laborers, wheeling, spreading and tamping, 142 days, at \$2.....	284.00	0.0072
Finishers, 47 days, at \$5.50.....	258.50	0.0066
Form setters, 37 days, at \$3.....	111.00	0.0029
Total, 28,920 sq. ft.....	\$887.50	\$0.0228

Cost of Cement Curb, Iowa.†—Data were given by Mr. M. G. Hall, in "Engineering News," April 2, 1908, relating to cement curb work. We have rearranged and analyzed the costs as follows. (For comments on the brick paving laid at the same time and place, see page 361.)

The cement curb material was mixed, 1 of cement to 3 of sand, in a ½-cu. yd. Smith mixer. The average cost of the three jobs, A, B and C, reduced to the same rates of wages, is given below. Job A was 2,000 lin. ft.; B was 10,000 lin. ft.; C was 20,000 lin. ft. The

*Engineering-Contracting, Oct. 14, 1908.

†Engineering-Contracting, June 23, 1909.

curb measured 5 x 18 ins. and was backed with cinders as shown in Fig. 13. The following costs are in cents per lin. ft.

	Job		
	A	B	C
Trenchmen, 20c per hr.....	3.44	3.50	1.70
Form setters, 35c per hr.....	2.74	4.03	1.63
Filling cinders, 20c per hr.....	0.47	0.62	0.50
Wheelers, 20c per hr.....	0.58	0.68	0.50
Shovelers (concrete), 20c per hr.....	0.50
Tampers, 20c per hr.....	0.24	0.37	0.40
Finishers, 35c per hr.....	0.42	0.70	0.56
Men on mixer, 22c per hr.....	0.99	1.34	0.44
Removing forms, 20c per hr.....	0.48	0.24	0.30
Backfilling, 20c per hr.....	0.78	0.64	0.80
Miscellaneous, 20c per hr.....	0.72	1.00	0.05
Water boy, 10c per hr.....	0.33	0.31	0.20
Team and driver, 40c per hr.....	3.86	3.71	0.50
Concrete wagon, 40c per hr.....	1.20
Foreman, 35c per hr.....	2.28	1.50	1.13
Total labor	17.33	18.62	10.41
Cement, at \$1.40 bbl.....	7.65	7.76	7.73
Sand, at \$1.05 ton.....	3.45	3.51	3.50
Cinders	2.00	2.00	1.00
Total materials	13.10	13.28	12.23
Grand total	30.43	31.89	22.64

Since it takes 43 lin. ft. of 5 x 18-in. curb to make 1 cu. yd., the above items must be multiplied by 43 to reduce to a cubic yard basis. Omitting the items of trenching, backfilling and handling

Eng. Conty.

Fig. 13. Cement Curb.

cinders, we see that the labor on Job C cost 7.4 cts. per lin. ft., which is equivalent to \$3.18 per cu. yd. of cement curb. The other two jobs were considerably more expensive, particularly in the items trenching and teaming.

None of the three was economically handled, as may be seen by comparison with the costs given on page 451, where the labor cost about half as much per cubic yard as on Job C, and far less than half as much as on Jobs A and B.

I would call attention to the fact that curbs often differ considerably in cross-section, and the labor of mixing and placing the concrete therefore differs materially when compared in terms of the

lineal foot as the unit. Hence all costs should also be reduced to the cubic yard basis also. When this is done, a contractor will frequently find that his work is not being handled with the expedition that it should be; for comparison with the cubic yard cost of other jobs of similar character may disclose to the contractor a weakness of management or laziness of men on his own job. This is well exemplified in the above costs recorded by Mr. Hall.

Cost of Cement Curb.*—The concrete curb shown in Fig. 14 was built at an average labor cost of 6 cts. per lin. ft. The labor force employed on the work was as follows:

	Per day.
3 laborers, at \$1.75.....	\$14.00
1 finisher, at \$3.00.....	3 00
1 working foreman, at \$4.00.....	4 00
Total, 350 lin. ft., at 6 cts.....	\$21.00

This force averaged 350 lin. ft. of curb per day of 10 hrs. For the body of the curb, $1\frac{1}{4}$ yds. gravel and 7 sacks of Portland cement in

Fig. 14. Cement Curb.

a batch would make 60 lin. ft. of curb. For the outside finish a batch was made of 18 pails of screened gravel mixed with 4 sacks (12 pails) of Portland cement

The cost of the materials was as follows, not including the outside cement finish.

	Per lin. ft.
0.03 cu. yd. gravel, at \$1.25.....	\$0.0375
0.03 bbl. cement, at \$2.40.....	0.0720
Total	\$0.1075

For the above information we are indebted to Mr. A. W. Saunders, of Johnstown, Pa.

Cost of Cement Curb and Gutter.—The following costs were recorded by Mr. Charles Apple, and relate to work done at Champaign, Ill., in 1902. The work was done by contract, at 45 cts. per lin. ft. of the curb and gutter shown in Fig. 15.

The concrete curb and gutter was built in a trench as shown in the cut. The earth was removed from this trench with pick and shovel at a rate of 1 cu. yd. per man per hour. The concrete work was built in alternate sections, 7 ft. in length. A continuous line of planks was set on edge to form the front and back of the concrete

**Engineering-Contracting*, June 10, 1903.

curb and gutter; and wood partitions, staked into place, were used. The cost of the work was as follows:

COST OF CURB AND GUTTER.				
	No. of men.	Lin. ft. per day.	Total wages.	Cost per 100 ft.
Opening trench, 18 x 30-in.....	2	144	\$3.50	\$2.43
Placing and tamping cinders.....	2	350	3.50	1.00
Setting forms:				
Boss setter	1	...	3.00	...
Assistant setter	1	...	2.00	...
Laborer	1	...	1.75	...
Total setting forms.....	3	400	\$6.75	\$1.69
Mixing and placing concrete:				
Clamp man	1	...	\$1.75	\$0.50
Wheelers	3	...	5.25	1.50
Mixing concrete	4	...	7.00	2.00
Mixing finishing coat.....	2	...	3.50	1.00
Tamperers	1	...	1.75	0.50
Finishing:				
Foreman and boss finisher.....	1	...	4.00	1.14
Assistant finisher	1	...	3.00	0.88
Water boy	150	1.14
Total making concrete....	14	350	\$26.75	\$ 7.64
Total for labor per 100 ft....				\$12.76
Materials for 100 lin. ft.:				
	Quantity.		Price.	
Portland cement	8½ bbls.		\$1.85	\$15.42
Cinders	7½ yds.		.50	3.75
Gravel	2.5 yds.		1.00	2.50
Broken stone	2.5 yds.		1.40	3.50
Sand	1.0 yds.		1.00	1.00
Total for material per 100 ft.....				\$26.17
Total for material and labor per 100 ft.....				\$38.93

Fig. 15. Cement Curb and Gutter.

This is the total cost, exclusive of lumber, tools, interest, profits, etc., and it is practically 40 cts. per lin. ft.

In 100 lin. ft. of curb and gutter there were 46 cu. yds. of concrete and mortar facing, 4 cu. yds. of which were concrete; hence the 9 men in the concrete gang laid 14 cu. yds. of concrete per day, whereas the 4 men mixing and placing the mortar finishing laid

only $2\frac{1}{2}$ cu. yds. of mortar per day, assuming that the mortar finishing averaged just 1 in. thick. Since these 4 men (2 mixers and 2 finishers) received \$10.50 a day, it cost more than \$4 per cu. yd. to mix and place the 1:2 mortar, as compared with \$1.41 per cu. yd. for mixing and placing the concrete. The concrete was built in alternate sections 7 ft. long. The 3 men placing forms averaged 400 lin. ft. a day, so that the cost of placing the forms was \$1 per cu. yd. of concrete. The 2 men placing and tamping cinders averaged 16 cu. yds. of cinders per day, or 8 cu. yds. per man. This curb and gutter was built by contract at 45 cts. per lin. ft.

For several jobs, in which a curb and gutter essentially the same as shown in Fig. 15 was built, my records show a general correspondence with the above given data of Mr. Apple. Our work was done with smaller gangs, 1 mason and 2 laborers being the ordinary gang. Such a gang would lay 80 to 100 lin. ft. of curb and gutter per 10-hr. day, at the following cost:

1 mason, at \$2.50.....	\$2.50
2 laborers, at \$1.50.....	3.00
Total	\$5.50

This made a cost of $5\frac{1}{2}$ to 7 cts. per lin. ft. for labor, and it did not include the cost of digging a trench to receive the curb and gutter.

Cost of Cement Curb, Baltimore, Md.—I give the following abstract from an article in *Engineering-Contracting*, Sept. 22, 1909, merely to show how high the cost of a cement curb may be when built by day labor instead of by contract. This work was done in Baltimore, in 1908, by city forces, at the following cost:

	Per lin. ft.
0.037 cu. yd. crushed stone, at \$1.75.....	\$0.065
0.02 cu. yd. sand, at \$0.80.....	0.015
0.05 bbl. cement, at \$1.29.....	0.064
Total concrete materials.....	\$0.144
Wainwright iron bar.....	0.150
Frogs	0.010
Total materials	\$0.304
Labor	0.506
Grand total	\$0.810

The gang engaged in making this curb was as follows per 8-hr. day:

	Per day.
1 foreman	\$ 4.00
1 finisher	2.50
3 laborers, at \$1.66 $\frac{2}{3}$	5.00
1 cart, horse and driver.....	2.50
Total, 28 lin. ft., at 50 cts.....	\$14.00

The curb measured 6 ins. thick by 24 ins. high, or 1 cu. ft. per lin. ft., and the concrete was mixed 1:2 $\frac{1}{2}$:5. Since the labor cost 60 cts. per lin. ft., this is equivalent to \$13.50 per cu. yd.! So far as I know, this breaks all records for high cost of cement curb work. Of course the "contractors' profits" were saved.

Cost of Cement Curb and Gutter, Ottawa, Ont.*—The method and cost of constructing 1,336 ft. of cement curb and gutter at Ottawa, Ont., are given in some detail by Mr. G. H. Richardson, Assistant City Engineer. We have remodeled the description and rearranged the figures of cost in the following paragraphs.

The concrete curb was built before doing any work on the roadway, and the first task was the excavation of a trench $2\frac{1}{2}$ ft. wide and averaging 1 ft. 8 ins. in depth through light red sand. On the bottom of this trench there was placed a foundation of stone spalls 8 ins. thick; in width this foundation reached from 3 ins. back of the curb to 6 ins. beyond the front of the water table. The curb was made 6 ins. thick and ran from 10 ins. to $5\frac{1}{2}$ ins. in height, and the water table was 14 ins. wide and 4 ins. thick, with a fall of $1\frac{1}{2}$ ins. from front to back. The concrete used was a mixture of 1 of Portland cement, 3 of sand, 3 of $\frac{1}{2}$ -in. screened limestone, and 4 of 2-in. stone. It was deposited in forms and tamped to bring the water to the face and then smoothed with a light troweling of stiff mortar.

The forms were constructed by first setting pickets and nailing to them a back board 2 ins. thick and 12 ins. wide and a front board 2 ins. thick and 6 ins. wide. The concrete for the water table was deposited in this form in sections and brought to surface by straight edge riding on wooden strips nailed across the form and properly set to slope, etc. After the water table had been troweled down and brushed a 1 x 10-in. board was set to mold the front face of the curb. This board was sustained by small "knee frames" made of three pieces of 1 x 2-in. stuff, one conforming to the slope of the water table and long enough to extend beyond the front of the 2 x 6-in. front board, a second standing plumb and bearing against the 1 x 10-in. face board, and the third forming a small corner brace between the two former to hold them in their proper relative positions. The 1 x 10-in. face board, etc., was separated from the 2 x 12-in. back board by a 5-in. block at each end, and then braced by the knee frames every 3 or 4 ft. In this way it was possible to bring this 1 x 10-in. board into perfect line by moving the knee braces in or out, and when correct nailing them to the 2 x 6-in. front board. The 1 x 10-in. face board being in position and braced and lined, the curb material was thoroughly tamped in, and when ready was troweled and brushed on the top, a small round being worked onto the top front corner with the trowel.

Expansion joints were provided for by building into the curb every 12 ft., a piece of $\frac{1}{2}$ -in. boiler plate, which was afterward withdrawn and the joint filled with sand and faced over. As soon as the concrete had set sufficiently the face board was taken down and face of curb finished and brushed, the fillet between curb and water table being finished to $2\frac{1}{2}$ ins. radius. Circular curb and gutter of same construction was built at each corner, $\frac{1}{2}$ -in. bass-wood being used for forms, instead of 2 x 1-in. lumber.

**Engineering-Contracting*, Nov. 12, 1907.

In addition to the actual construction of curb and gutter the cost given below includes the cleaning up of the street, spreading or removal of all surplus material from excavation, and the extension of all sidewalks out to the curbs at the corners. It was also necessary to maintain a watchman on this work, which duty, under ordinary circumstances, would be done by the general watchman. The total length built was 1,326 ft., of which 1,209 ft. is straight and 117 ft. curved to a 12-ft. radius.

The rates of wages paid were \$2 for horse and cart, \$1.65 for watchman, and an average of \$1.90 per day for labor, including foreman; all for nine hours' work per day. The working force consisted of 1 foreman, 1 finisher, 1 handy man, 4 concrete men, and 3 laborers, total 10 men.

The labor cost of the work was as follows:

Labor:	Total.	Per lin. ft. Cts.
Excavation and setting boards.....	\$ 88.90	0.7
Laying stone foundation.....	43.30	3.2
Concreting	61.30	4.6
Finishing	45.15	3.4
Carting	9.85	0.76
Watchman	25.00	1.89
Clearing up	13.60	1.04
Extras (sidewalk extensions).....	17.28	1.31
Total	\$304.33	23.00

The cost of materials for curb and foundation were as follows:

Materials:	Total.	Per lin. ft. Cts.
171.112 tons spalls.....	\$103.93	7.76
42 tons 2-in. stone.....	41.16	3.09
30.8 tons $\frac{3}{4}$ -in. stone.....	42.67	3.21
33,000 lbs. cement	161.70	12.19
24 cu. yds. sand.....	19.20	1.46
Total	\$367.56	27.70

The cost of supplies and tools was as follows:

Supplies, Etc.:	Total.
1,000 ft. B. M. 2 x 12 boards charged off.....	\$ 9.25
500 ft. B. M. 2 x 6 boards charged off.....	4.12
1,000 ft. B. M. 1 x 10 boards charged off.....	14.25
$\frac{1}{2}$ -in. basswood	4.30
$\frac{1}{2}$ keg 3-in. nails.....	1.42
$\frac{1}{2}$ keg 4-in. nails.....	1.43
Pickets	2.25
Tools charged off.....	3.16
Total	\$41.17

This total, when divided by 1,326 lin. ft. of curb, gives the cost per lineal foot as about 3 cts. We can now summarize as follows:

Item.	Total.	Per lin. ft.	P. C. of total.
Labor	\$304.33	\$0.23	43
Material	367.56	.28	51
Supplies	41.17	.03	6
Total	\$713.06	\$0.54	100

As indicated above, on more extensive work the costs of carting, watchman, cleaning up, and extras would be avoided. They cost

on this work 5 cts. and the work could therefore be done for 49 cts. if no such charges were included. On such work also the charge for supplies would be lower per foot and on any future work the labor cost could be materially lowered, this curb having been somewhat of an experiment as to method of construction. It is thought that with no charges for carting, cleaning, watchman, and extras, and with the experience obtained, this curb could be built for about 46 cts. The proportions adopted and the method of construction followed, produce a very strong, dense, homogeneous curb and gutter.

Cost of Setting Stone Curbs.—After the trench has been dug and foundation prepared, a mason and a helper will set 225 lin. ft. of stone curb in 10 hrs. If the mason receives 35 cts. per hr., and his helper receives 20 cts. per hr., the placing of the curb costs 2½ cts. per lin. ft. This cost is based upon the work of laying several thousand feet of dressed Medina sandstone curb, 24 ins. deep, and does not include any dressing of the stone. The men were not very efficient.

Cost of Cutting and Setting Granite Curb, N. Y.*—The work was done by a contractor on a New York City street, and involved the dressing and setting of 1,560 lin. ft. of granite curb. Each curb cutter cut 28½ lin. ft. of curb per day, and each curb setter set 184 lin. ft. per day. The labor cost was as follows:

	Per lin. ft.
0.0352 day curb cutter, at \$4.00.....	\$0.141
0.0058 day curb setter, at \$4.00.....	0.023
0.0120 day curb setter's helper, at \$2.00.....	0.024
Total	\$0.188

These men were very inefficient or poorly managed.

Cost of Resetting Curb, N. Y.†—On Broadway, between 110th and 119th street, 2,253 lin. ft. of stone curb was set in 1904. Of this only 500 ft. was new curb, the rest being old curb that was taken up, dressed and reset. The work was done by a contractor, whose men worked an 8-hr. day, and the actual costs were as follows:

<i>Excavation:</i>		Rate per day.	Per lin. ft.
Foreman		\$3.75	\$0.004
Laborers		1.50	.020
Total per lin. ft.....			\$0.024
<i>Concrete:</i>		Rate per day.	Per lin. ft.
Foreman		\$3.75	\$0.004
Laborers		1.50	.026
Total per lin. ft.....			\$0.03
<i>Setting and Dressing Curbs:</i>		Rate per day.	Per lin. ft.
Stonecutters		\$5.00	\$0.12
Curb setters		4.00	.012
Curb setters' help.....		2.50	.025
Total per lin. ft.....			\$0.157

*Engineering-Contracting, June 20, 1906.

†Engineering-Contracting, May 16, 1906.

It should be noted that in the table the excavation under curb is for the taking up of the old curb and making excavation for new curb.

The concrete for the curb foundation required twenty-nine loads of stone costing \$72, sixteen loads of sand at a total cost of \$35, and 160 bags of cement at a total cost of \$64. The total cost of the material for the curb foundation amounted to \$171.

Recording Cost of Street Sprinkling.—No record of the cost of street sprinkling is entirely satisfactory unless it shows:

1. The average daily wage of team and driver on the sprinkling wagon.
2. Number of miles of street of given width kept sprinkled each day by each sprinkling wagon.
3. Number of gallons of water averaged per day per square yard of street, of given kind of pavement, during the sprinkling season (usually Apr. 1 to Oct. 31 in the North).
4. Number of days that sprinkling was done during the year.
5. Cost per sq. yd. for the year for (a) water and (b) team time sprinkling it.

Contracts have often been let on the basis of a given price per 1,000 sq. yds. for sprinkling during the dry season. This form of contract is objectionable in that disputes are very apt to arise over the inspection of the work. What seems sufficient sprinkling to the contractor may seem quite insufficient to the inspector. I am strongly in favor of doing all sprinkling by contract, but the contract should be based, not upon the number of square yards sprinkled a stated number of times daily for a stated number of days, but upon the number of gallons sprinkled from a nozzle of specified kind. This involves metering the sources of water supply, which, however, is an expense of slight consequence.

The cost of sprinkling depends primarily upon the amount of water loaded into the tank, hauled and spread upon the street; hence the gallon is the proper unit of cost. Obviously, however, the kind of sprinkler or nozzle from which the water flows should be specified, so that too much water will not be put upon the street at one time and place.

Such a contract is flexible as to the number of sprinklings—depending on the weather—and is exact as to its payment in proportion to work done. Nor can it fail to be far cheaper, in the long run, than any attempt to do the sprinkling by day labor forces working for the city.

Cost of Street Sprinkling, Washington, D. C.*—About 40 miles of streets and roads in the District of Columbia are sprinkled each day upon which weather conditions were such as to render it necessary. The District owns its own sprinklers and teams and hires the drivers. In all 19 sprinklers are used, four on the heavily traveled

**Engineering-Contracting*, Dec. 4, 1907.

car-track paved streets, and 15 on macadam and dirt streets or roads.

Each sprinkler is required to cover two miles of territory from 8 a. m. to 5 p. m., at least three times each day. The sprinklers are 2-horse wagons, and have a capacity of 450 gallons each. On the average, it is necessary to fill the tanks about every $2\frac{1}{2}$ squares, or a distance in one direction of 1,750 ft.

The dimension of the spray nozzle on the inside is $4\frac{1}{2}$ ins. in diameter, and the holes through which the water-flows vary from $\frac{2}{32}$ ins. to $\frac{4}{32}$ ins. and cover a diameter of $2\frac{1}{2}$ ins.

The water is supplied free of charge, and drivers are paid \$1.75 per day, in addition to which it is estimated that the cost of maintaining the 2 horses, repairs, etc., is about \$1.25 per day, or a total of \$3.00 for each day per wagon for each day upon which work is performed.

The cost of the sprinkling for the fiscal year ending June 30, 1907, was as follows:

Drivers	\$ 4,621.27
Forage, pro rata.....	4,863.77
Horseshoes and nails, pro rata.....	218.55
Incidental expenses, pro rata.....	419.13
Miscellaneous expenses, pro rata.....	830.48
Wages of extra laborers.....	1,289.18

Total, 40 miles, at \$306.....\$12,242.31

The total number of days worked was 195.

The cost of maintaining and operating each sprinkler for the fiscal year was about \$644, or \$3.30 per sprinkler per day worked. Since each sprinkler covered 2 miles of street, or about 37,500 sq. yds. daily, the total cost of sprinkling (exclusive of the cost of the water) was $\$644 \div 37,500 \text{ sq. yds.} = 1.72 \text{ cts. per sq. yd. per season}$ (of 195 days), for sprinkling three times daily.

Cost of Sprinkling Streets and Roads.—Mr. J. J. R. Croes says that to keep down the dust in Central Park, N. Y., from April 1 to Oct. 31 (7 mos.), about 100 cu. ft. (750 gals.) of water were used daily per 1,000 sq. yds. of macadam, the greatest amount on any one day being 157 cu. ft. per 1,000 sq. yds. Carts holding 41 cu. ft. of water were used. From the above it appears that about 160 gals. of water were used per sq. yd. of macadam during the 7 mos.

Mr. E. P. North states that to keep down the dust on an earth road, water applied twice daily, there were 143 cu. ft. (1,070 gals.) of water used daily per 1,000 sq. yds. A sprinkling cart holding 60 cu. ft. covered 850 sq. yds., or about $\frac{1}{2}$ gal. per sq. yd.

Mr. E. W. Howe gives the cost of sprinkling park (macadam) roads. The road was sprinkled 10 times daily to keep the dust down, a sprinkler with fine holes being used.

	Per mile per year.
1,170,000 gals. water, at 16 cts. per 1,000 gals.....	\$187
Teams	533
Total	\$720

Unfortunately the width of these park roads is not given, so that it is impossible to arrive at the amount of water or cost per sq. yd.

Amount of Water for Sprinkling Streets, Indianapolis and Minneapolis.—Mr. F. A. W. Davis gives the following. In Indianapolis, during the year of 1892, from Apr. 1 to Oct. 31 (7 mo.), 14,800,000 sq. ft. of streets were sprinkled, using 7.1 gals. per sq. ft., or 64 gals. per sq. yd., for the season. The water was metered and paid for at 8 cts. per 1,000 gals. (or \$80 per 1,000,000 gals.). Hence the water cost \$0.005, or $\frac{1}{2}$ ct. per sq. yd., or about $\frac{1}{2}$ mill per sq. ft. The sprinkling was done by contract, the prices ranging from \$38 to \$48 per 10,000 sq. ft., which is equivalent to 3.4 ct. to 4.3 ct. per sq. yd., for the season. The streets were sprinkled 3 to 4 times daily. Hence these contract prices were high.

During 1893 there were 8 gals. used per sq. ft., or 72 gals. per sq. yd.

It is stated that in Minneapolis, during 1893, each team on a sprinkling cart averaged 7,100 lin. ft. of street sprinkled per day, which is nearly 1.4 miles of street, there being 150 carts employed in sprinkling 207 miles of street. During two of the driest months of summer, 10,000,000 gals. were used per day, which is nearly 50,000 gals. per mile per day. The width of streets is not stated, but if they averaged 32 ft., there were 2.67 gals. of water per sq. yd. per day, during the two driest months.

Sprinkling Car Tracks.—The cost of sprinkling the street car tracks of the Detroit United Railway of Detroit, Mich., amounts to \$4,123 per season; the company has eight sprinkling cars in operation, the cost for each car per year thus being \$511. Two of the cars have tanks of a capacity of 3,870 gallons each, and six cars have a tank capacity of 3,702 gallons each. A car having a tank capacity of 3,702 gallons sprinkles at one filling 3.3 miles of track to a width of 8 ft. The rate per hour is $10\frac{1}{2}$ miles.

Recording Cost of Street Sweeping.—Very rarely does an annual report on municipal street sweeping contain the data in form that admits of comparison with other cities. Sweeping cost data should be so compiled as to show the following:

1. The organization of the workmen, the numbers in each class, and their respective daily wages.
2. The average daily wage.
3. The number of days worked by the average workman during the fiscal year.
4. If possible, the average number of times all streets were swept during the year.
5. The cost of this sweeping per sq. yd. of street per year.
6. The cost per 1,000 sq. yds. for one sweeping.
7. The number of loads and cu. yds. of sweepings removed.

It is further desirable, where there are several different kinds of pavements, to give the unit costs of sweeping each class.

Where machines are used, their kind and number, as well as the methods of doing the work should be stated.

A common cost of sweeping is about 20 cts. per 1,000 sq. yds. swept once. Hence if a street is swept 3 times a week, or 156 times a year, the cost is 3.12 cts. per sq. yd. per year for sweeping.

It is commonly believed that street cleaning can not be well done by contract, due to the difficulty of specifying exactly what is wanted and of determining by inspection whether the contract is being lived up to. This is undoubtedly true where the attempt is made to contract at a given price per sq. yd. of street per year. On the other hand, it has been demonstrated in Washington, D. C., and elsewhere, that much of the difficulty vanishes when a contract is made on the basis of 1,000 sq. yds. swept once. Then, if, say, 3 sweepings a week does not give satisfactory cleanliness, the number of sweepings can be increased and paid for at the contract price of, say, 20 cts. per 1,000 sq. yds. swept once.

Under such a contract, the contractor should be required to work his men in fairly large gangs, and under the general direction of the city's representative. Under the "patrol system" of sweeping, each street cleaner is assigned a certain length of street to keep clean. This is a fairly satisfactory method where work is done by day labor by the city; but it is not an economic method, nor one to be generally used. The German method of having men work in large gangs is far more economic. It possesses the very important advantage of enabling one to know exactly how many times each street has been actually swept over each week, and thus makes it possible to determine what it has cost per 1,000 sq. yds. for each sweeping. As this is the only unit of cost of sweeping that admits of a rational comparison of the cost in different cities, or of the cost in different sections of the same city, it is obviously of the utmost importance to adopt the "gang system" and abandon the "patrol system" of sweeping.

Cost of Street Sweeping in 35 Cities.—In January, 1900, Mr. Andrew Rosewater, City Engineer of Omaha, Neb., collected the data shown in Table XIX. It will be noted that he secured the actual costs for the year 1898; and that the costs for 1899 were estimated, but probably close to actual. It is unfortunate that the data were not secured to show how many times the average street was swept in each city, for then we could have determined what it cost per 1,000 sq. yds. swept once.

Excluding New York, Chicago, Philadelphia and Pittsburg, the 31 remaining cities have 3,670 miles of paved streets with an area of 71,439,091 sq. yds. Hence the average width of pavement is 33½ ft., which is equivalent to 3.7 sq. yds. per lin. ft. of street, or 19,800 sq. yds. per mile. The estimated cost of cleaning these 31 cities in 1899 was \$2,305,895 (including Newark and Minneapolis on the basis of 1898). This is equivalent to 3.23 cts. per sq. yd. of pavement for the year, or \$32.30 per 1,000 sq. yds.

Assuming that the pavements of Chicago, Philadelphia and Pitte-

burg also averaged 33 1/2 ft. wide, the cost of cleaning the four large cities was:

	Per sq. yd. Cts.
New York	18.0
Chicago	2.8
Philadelphia	3.1
Pittsburg	3.8

The shameful record of New York is well seen by this contrast.

There has been no improvement in New York since 1899. In fact the unit costs of cleaning have risen. In 1906 the boroughs of Manhattan and the Bronx, had 635 miles of paved streets, 12,366,000 sq. yds. and a population of 2,516,502. The cost of street sweeping alone was \$1,586,482, or 12 7 cts. per sq. yd. The cost of carting all the refuse, ashes, garbage, and street sweepings, was \$1,211,899. This material was carried away in scows and deposited in dumps at a cost of \$775,249, making a total of nearly \$2,000,000, of which at least 17% should be charged against the street sweepings, or \$340,000, as that was their relative number of cart loads. This is equivalent to 2.8 cts. per sq. yd. of pavement. Administration expenses added 6%, or another 1.0 ct. per sq. yd., making a total of 16.5 cts., without any allowance for interest and depreciation on the plant (horses, carts, etc.), or for rents and miscellaneous, which were fully 2 cts. more per sq. yd. The city accounts are so kept that complete unit costs are almost impossible to secure from the annual reports. Political misrule is written all over these New York City cost records.

Cost of Street Cleaning, Washington, D. C.—The street cleaning work of Washington covers an area of 7,686,936 sq. yds. Of this amount 1,745,452 sq. yds. of paved streets are cleaned by hand patrol work; 3,246,297 sq. yds. of paved streets are cleaned by machine sweeping; 1,734,400 sq. yds. are unpaved streets; and 961,737 sq. yds. are public alleys, paved and unpaved.

The hand patrol work is done by municipal forces, a summary of the work done by them during the fiscal year ending June 30, 1907, being as follows:

Number of days worked.....	381
Number of men employed.....	184 to 215
Area cleaned, sq. yds.....	497,811,216
Area cleaned, miles	22,230
Debris removed, cu. yds.....	38,952
Bags of paper removed.....	56,292

From this it is evident that since 1,745,452 sq. yds. of street involved sweeping an area of 497,811,216 sq. yds., these streets must have been swept 385 times during the year, or not quite once every day.

The cost of the work was as follows for each sweeping:

	Total.	Per 1,000 sq. yds.
Labor	\$82,336.91	\$0.165
Materials, etc.	5,238.14	.017
Total	\$90,675.05	\$0.182

*Engineering-Contracting, Nov. 27, 1907.

TABLE XIX.—STREET CLEANING IN 25 AMERICAN CITIES.

Cities.	Popula- tion.	Sq. yds. of paving.	Paved streets, miles.	Cost of cleaning paved streets,†		Per 1,000 sq. yds.	—†Wages—		Re- marks.
				Actual 1898.	Estimated 1899.		Men.	Team.	
New York, N. Y.	2,550,000	30,423,800	1,396	\$4,258,707	\$5,476,088	\$179.99	\$723	\$3.50	
Chicago, Ill.	1,351,000	1,248	675,000	510,722	
Philadelphia, Pa.	1,250,000	850	645,451	245,000	1.50	2.76	
St. Louis, Mo.	630,000	3,783,428	422	220,856	245,000	64.75	1.66%	2.35

*Includes \$2,000 for removal of snow and ice. †Assuming that all paved streets in each city are cleaned.
 ‡Per annum.

§Cleveland reported that 9 hours constituted a day's work; 8 hours was reported for Buffalo, Detroit, Pittsburgh, Omaha, Allegheny, Los Angeles, Albany, and St. Joseph; the other places did not report.

Note.—The letters in the Remarks Column indicate the following: C, sweeping and sprinkling at the time of sweeping done by contract; D, sweeping and labor; E, sweeping done by contract but sprinkling at the time done by day labor. All cities except Dayton and Trenton, reported that machines were

The item materials, etc., included the following:

Bamboo, bass and blocks	\$1,268.47
Bags	1,920.00
Corn brooms	108.00
Horse shoes and nails, pro rata.	141.85
Forage, pro rata	3,157.18
Incidental expenses, pro rata.	279.12
Miscellaneous	1,415.52
Rent of tool house	48.00
Total	\$8,318.14

The cost of hand cleaning per cubic yard of debris removed, exclusive of waste paper, was \$2.269, as against \$2.091 in 1906, the increase being due to the longer haul.

The average width of the streets cleaned was 38 ft., and the cost per mile of cleaning was \$4.05. A total area of 1,745,452 sq. yds. was gone over each day. The wage paid laborers was \$1.50 per 8-hr. day, and each laborer had an average street service area of between 9,000 and 10,000 sq. yds.

The cost of this hand sweeping was 5.2 cts. per sq. yd. of pavement per year, which is just twice what the machine sweeping cost, due principally to the fact that the machine swept streets were only swept 115 times during the year.

A total of 55,292 large sacks of paper was gathered in the hand cleaning district alone, an average of 200.3 sacks per working day. Only a small proportion of this amount was taken from the waste paper boxes placed at different points throughout the business district. In order to keep the streets and sidewalks within the hand cleaning territory free of paper during the daytime an average of two hours out of the eight was devoted by the laborers to picking it up. For this purpose the men were required to go over their respective sections four times per day the first thing in the morning, before lunch, after lunch, and toward the end of the working day.

The machine sweeping of paved streets (3,245,297 sq. yds.) was done by contract, a summary of the work accomplished for the fiscal year 1907 being as follows:

Number of days worked	241 1/4
Area cleaned, sq. yds.	373,029,844
Area cleaned, miles	16,732
Debris removed, cu. yds.	86,814
Contract price per 1,000 sq. yds. per sweeping	\$0.22%
Cost per mile per sweeping.	\$5.07

The area covered by machine sweeping was as follows:

Area, sq. yds.	3,245,297
Cost per sq. yd. per year.	2.62 cts.
Area, miles	145.6
Average width of paved street, ft.	38
Area cleaned per day, sq. yds.	1,991,465
Area cleaned 6 times per week, sq. yds.	737,638
Area cleaned 3 times per week, sq. yds.	1,253,832
Average number of times streets were swept.	115

A summary of the work of cleaning the unimproved streets

(1,734,440 sq. yds.), consisting of rough cobblestone, macadamized, gravel and dirt roads and streets is as follows:

Number of days worked	276
Area cleaned, sq. yds.	31,007,419
Area cleaned, miles	1,652
Debris removed, cu. yds.	20,235
Contract price per day for full force	\$73.80
Cost per 1,000 sq. yds. per sweeping	\$0.586
Cost per mile per sweeping	\$11
Average number of times streets were swept	18

The total area of unpaved streets was 1,734,440 sq. yds., the average width being 32 ft. A total area of 214,195 sq. yds. was cleaned each day.

The cleaning of public alleys (941,737 sq. yds. paved and unpaved) was done by contract, a summary of the work done being as follows:

Number of days worked	250
Area cleaned, sq. yds.	44,131,506
Area cleaned, miles	6,269
Average width of alleys, ft.	12
Debris removed, cu. yds.	12,288
Contract price per 1,000 yds. per sweeping ..	\$0.40
Cost per mile per sweeping	\$2.816
Average number of times swept	46

Cost of Sweeping Streets Washington, D. C.—Mr. Warner Stutler gives the following:

During the year, July 1, 1901-02, 1,565,809 sq. yds. asphalt were swept daily by hand. There were 200 men, at \$1.25, and 9 teams. The total area cleaned was 413,765,028 sq. yds., at a cost of 13.6 cts. per 1,000 sq. yds. for each sweeping.

The number of times swept during the year was $413,765,028 \div 1,565,809 = 264$. Hence the cost per sq. yd. of pavement per year, for sweeping, was 4.9 cts.

Then a "pick-up" sweeper ("The Peerless," made by Barron & Cole, of New York City) was adopted, with which a laborer could clean 32% more area daily than with hand brooms and do better work.

Cost of Sweeping With a "Pickup" Sweeper.*—During the summer of 1907 Mayor Geo. B. McClellan appointed Mr. H. de B. Parsons, Dr. Rudolph Hering and Mr. Samuel Whinery a commission to report on an improved and more effective system of street cleaning and waste disposal than is now in operation in New York City. At the end of the year this commission made its report, which has since been printed by the city.

The report covers nearly 250 pages, and has in it much valuable information on street cleaning and waste disposal. The commission has made a study of many features of this kind of work, and has collected a large amount of data on the subject.

The report discusses at some length the various methods used

**Engineering-Contracting*, May 6, 1908.

in street cleaning, and gives an estimated cost for each method described, thus allowing a comparison of each with the other. The estimate on hand sweeping by the "patrol method" is as follows:

Cost of one outfit:

One hand cart	\$10.00
Five cans for sweepings, at \$2.50.....	12.50
Four hand brooms, at 65 cts.....	2.60
One shovel	0.75
Two steel scrapers, at \$2.....	4.00

Total

\$29.85

Annual charges:

Interest on outfit at 4%	\$ 1.19
Repairs and depreciation at 60%.....	17.01

Total annual charges

\$18.10

Or for 310 days, per day.....

\$0.062

Cost of operation per day, 1 man sweeping

2.190

Total cost per day.....

\$2.252

On the basis that one sweeper will clean satisfactorily 8,000 sq. yds. of pavement per day the cost per 1,000 sq. yds. will be 28.1 cts.

In closing their remarks on hand sweeping the commissioners said:

"A modified method of hand sweeping in use in a number of American and foreign cities consists in substituting for the ordinary push broom a small machine with a revolving broom. This machine is generally similar to the large machine sweeper, except that it is designed to pick up its own sweepings and deposit them in an attached receptacle, which is emptied when necessary. This small machine is pushed over the street by the street sweeper and does its work quite well when the street is dry. It is extensively used in Washington, where it is well liked. One objection is that on heavy traveled streets there is difficulty in working it among horses and vehicles. Upon the whole, this hand sweeping machine is not in general favor in American cities."

It is to be very much regretted that this commission of eminent engineers did not make a thorough investigation of this sweeping machine and report their findings on it. This type of machine seems to us to solve some of the problems of street cleaning, and in this article we give some data that we have collected. We realize that there can be some objection to any method, but on good pavements these machines can effect a saving over the patrol hand sweeping, and at the same time do much more efficient work.

This style of machine has been used in Washington, D. C., since the summer of 1901, and, as the commission states, "it is well liked." The name of the machine used in Washington is the "Peerless," sold by Barron & Cole, of New York City.

Prior to the installation of these machines in Washington a patrol sweeper swept daily 7,458 sq. yds., and with the pick-up machine the same man covered 9,145 sq. yds., an increased area of more than 22 per cent. In order to compare this with the costs given above the same wages will be applied. Thus we have:

<i>Cost of one outfit:</i>	
One Peerless hand sweeper.....	\$75.00
Forty bags	4.00
Four upright brooms at 35 cts.....	1.40
One shovel75
One steel loosener40
Total	\$81.55
<i>Annual charges:</i>	
Int. on outfit at 4%.....	\$ 2.26
Four new brooms at \$4.....	16.00
Depreciation at 20%.....	16.31
Total annual charges.....	\$25.57
Or, for 310 days, per day.....	\$0.114
One man	2.190
Total cost per day	\$2.304

With the area of 9,145 sq. yda. swept per day this gives a cost per 1,000 sq. yda. of 25.1 cts., or just 3 cts. less than the estimated cost of the patrol sweeping.

The working day in Washington, like New York, is 8 hrs., but the machines are only operated 6 hrs. each day, as the men spend 2 hrs. each day in picking up paper. For this purpose the men are required to go over their respective sections four times per day—the first thing in the morning, before lunch, after lunch, and towards the end of the working day. It would seem possible that this paper could be cared for in some other way. With ordinances properly enforced the greater part of it should be put into boxes on the sidewalks by the users of the street, thus preventing the paper from being scattered in the street. With the waste paper eliminated and the men employed on the machines operating them 8 hrs., the area covered per day would be between 11,000 and 12,000 sq. yda. at a cost of about 20 cts. per 1,000 sq. yda. The style of box for depositing waste paper should be somewhat similar to the package mail boxes used by the government, as the self-closing lids prevent the paper from being blown out of the boxes by the wind.

Burlap bags should likewise be used for collecting the street sweepings, instead of cans. The bags are cheaper and better adapted to the work. The dirt receptacle on a sweeper ordinarily holds the sweepings of about 800 sq. yda. When the dirt is dumped from the sweeper it can be shoveled into a bag, the bag being held open on hooks made for the purpose on the handle of the machine. The bag can be tied up and placed on the sidewalk for the pick-up wagon to carry away. With a bag it is not possible, either, for the wind or some boy to scatter the dirt as with an open top can. With the machine carrying a bag on the hooks on the handle paper can also be picked up by the operator as he passes a piece and placed in the bag. With bags a larger load, without chance of spilling any dirt, can be carried on the pick-up wagon or cart.

Upright brooms are cheaper than push brooms, and can be used with this machine, as brooms are only needed to sweep the dirt away from curbs or in taking up the sweepings after the machines have been emptied.

The steel loosener has a long handle and is used to loosen any

materials that have become stuck to the pavement, the length of the handle admitting of this being done without the operator leaving his position behind the machine.

The machine uses up four brooms a year, and these have been charged in the annual expenses. The life of a machine is from 8 to 10 years, hence a depreciation of 20 per cent per year is more than ample to allow, and this will also cover renewals, as we are informed by the manufacturer that for about 200 machines used by the city of Washington the repair parts ordered during the past two years have not amounted to quite \$200, or a yearly expense of less than 50 cts. for each machine.

The great problem in street cleaning is the removing of the finer particles and the dust. The commission, in its report, dwells at some length on this. The coarser particles, they state, are easily cleaned up, but even when a street has been swept there still remains the dust, which is a "serious menace to health and a destructive and discomforting element of city life." The hand pick-up sweeper does not take up all of this dust, but it does take up the greater part of it, as is evident when one walks along Pennsylvania Ave. in Washington on a windy day, for it is possible to keep one's eyes open without having them filled with dust. In New York a puff of wind means a cloud of dust. On this point the superintendent of the street cleaning department of Washington, in his report dated June 30, 1902, in commenting on the work of these machines, said:

"The daily area cleaned, therefore, was not only enlarged and the expenses reduced, but the streets were kept cleaner than ever before."

Estimated Cost of Machine Sweeping.—In the Parsons-Hering-Whinery report, above mentioned, the cost of sweeping with horse-drawn machines (having revolving brooms) is estimated as follows:

<i>Cost of one outfit:</i>	
1 sweeping machine	\$ 275.00
1/2 of 1 one-horse sprinkling cart.....	104.00
12 hand brooms at \$0.65.....	7.80
6 shovels at \$0.75.....	4.50
2 horses for sweeper	600.00
1/2 horse for 1/2 sprinkler.....	150.00
2 1/2 sets of harness at \$25.....	62.50
Total outfit	\$1,203.80
<i>Annual plant charges:</i>	
Interest on \$1,203.80 at 4%.....	\$ 48.15
Repairs and depreciation on tools, at 20%....	90.76
Depreciation on horses, at 15%.....	112.50
Total, 310 days at \$0.81.....	\$ 251.41
<i>Operating expenses—</i>	
	<i>Per day.</i>
Maintenance of 3 1/2 horses at \$1.35.....	\$ 3.38
Rent, storage of sweeper.....	0.20
Wages, 1 sweeper driver	2.19
Wages, 1/2 sprinkler driver	1.09
Wages, 6 gutter sweepers, at \$2.19.....	13.14
Plant charges	0.81
15,000 gals. water at \$90 per million.....	1.35
Total, 70,000 sq. yds. at 31.7 cts. per 1,000	
sq. yds.	\$ 22.16

This is estimated for an 8-hr. day in New York City, and for an asphalt pavement. It does not include loading the sweepings into carts and carting away.

Estimated Cost of Flushing Streets.—In the Parsons-Hering-Whinery report, above mentioned, the cost of flushing New York streets with a horse and with a machine are estimated as follows:

Using a 2½-in. fire hose with a 1¼-in. nozzle, under a pressure of 40 lbs. per sq. in., 235 gals. per min. are discharged, and 4,000 to 10,000 sq. yds. are washed per hour. Assuming an average of 6,000 sq. yds. per hr., and that the water jet is operating 80% of the time, there would be 188 gals. used per sq. yd.

<i>The cost of one outfit is:</i>	
100 ft. of 2½-in. hose at \$1.10.....	\$110.00
1 fire nozzle	12.50
6 brooms	3.90
	<hr/>
	\$126.40

<i>Annual plant charges:</i>	
Interest on \$126.40 at 4%	\$ 5.06
Repairs and depreciation 150%.....	189.60
	<hr/>

Total, 310 days at \$0.63.....	\$194.66
--------------------------------	----------

<i>Operating expense:</i>		Per day.
3 men at \$2.19	\$ 6.57	
90,000 gals. water at \$90 per million.....	8.10	
Plant charges	0.63	
	<hr/>	

Total, 48,000 sq. yds. at 31.9 cts. per M....	\$15.20
---	---------

It was estimated that as rapid and as thorough work could probably be secured with a 1-in. special nozzle (on a 2-in. hose), throwing a fan-shaped jet, and with 30 lbs. per sq. in. pressure. Under such conditions, the cost of flushing was estimated thus:

	Per day.
2 men at \$2.19	\$ 4.38
57,600 gals. of water at \$90 per million.....	5.18
Plant charges	0.48
	<hr/>

Total, 40,000 sq. yds. at 25.1 cts. per M....	\$10.04
---	---------

Street flushing with special wagons was estimated as follows. The wagon has a tank with two airtight compartments, one holding water (600 gals.) and the other holding compressed air, the two being connected above the water line. When the water tank is filled with a hose, air is compressed in the air compartment. In flushing the water is forced out at a pressure of about 35 lbs. per sq. in. through a special nozzle.

<i>Cost of one outfit:</i>	
One flushing wagon	\$1,000.00
6 hand brooms at \$0.65.....	3.90
3 shovels at \$0.75	2.25
2 horses at \$300	600.00
2 sets harness at \$25	50.00
	<hr/>

Total	\$1,656.15
-------------	------------

<i>Annual plant charges:</i>	
Interest on \$1,656.15 at 4%.....	\$ 66.25
Repairs and depreciation on tools at 14%.....	147.86
Depreciation on horses at 15%.....	90.00
	<hr/>

Total, 310 days at \$0.98.....	\$ 304.11
--------------------------------	-----------

<i>Operating expenses:</i>	<i>Per day.</i>
1 driver	\$ 2.19
1/2 day helper	1.09
Maintenance 2 horses at \$1.35	2.70
4 men collecting dirt in gutters at \$2.00	8.80
Rent, storage of plant	0.20
Plant charges	0.98
56,000 gals. water at \$20 per million	5.64

Total 28,000 sq. yds. at 72.1 cts. per M...\$ 20.26

Cost of Street Sweeping, Minneapolis.*—The asphalt pavement of the city of Minneapolis, Minn., is swept by hand, using the Ross scraper according to the block system. Each man has from two to five blocks to keep clean. The sweepings are deposited in galvanized iron cans placed at street corners, from which they are removed by teams. The asphalt pavement is also swept by machine at night, and flushed whenever necessary.

The wages paid per day are as follows: Teams, \$4; men, \$1.50 to \$2.

According to the annual report of the city engineer, the cost of hand sweeping for 1906, 21 men being employed, was \$16,049, or 3.69 cts. per sq. yd. per year.

The cost of cleaning, machine sweeping and washing was \$9,276, or 5.02 cts. per sq. yd. per year.

A total of 11.65 miles of 27-ft. roadway cost per mile per year for cleaning, \$796; for sweeping, \$1,378, or a total of \$2,174.

In all 184,528 sq. yds. of asphalt pavement were cleaned and swept.

The cost of cleaning and sweeping the other paved (not asphalt) streets was \$43,014, or 3.33 cts. per sq. yd. This cost is for a yardage of 1,290,930 sq. yds., and does not include macadam and asphalt pavement. The cost of cleaning was 1.47 cts. per sq. yd., and the cost of sweeping was 1.86 cts. per sq. yd.

During 1899 there were 200,000 sq. yds. of asphalt pavement cleaned by hand by the block system. The sweepings were put into cans, from which they were collected by teams. The gang was 31 men at \$1.75 and 5 teams at \$3.50. The cost was:

	<i>Per sq. yd.</i>
	<i>Per year.</i>
	<i>Cts.</i>
Machine sweeping and washing	1.45
Hand sweeping	5.74
Total	7.19

Cost of Street Sweeping, Williamsport, Pa.†—Mr. James F. Fisher, City Engineer of Williamsport, Pa., in his report for 1907, gives the cost of sweeping the streets by machines.

The work is done by employees of city engineer's department, the force used and the wages paid being as follows:

**Engineering-Contracting*, Jan. 29, 1908.

†*Engineering-Contracting*, May 6, 1908.

One team on sprinkler	\$ 4.50
One team on sweeper	4.50
Two one horse pick up wagons	5.50
Four men 10 hrs. at \$1.65	6.60
Total for one day	\$21.10
Int. and depreciation of outfit	1.00
	<hr/> \$22.10

The one dollar added covers interest at 6% per annum and depreciation of the plant at 20% per year, divided by 200 working days, which is the length of the season in Williamsport.

Each day this force sweeps parts of seven streets aggregating 62,000 sq. yds. This gives a cost per 1,000 sq. yds. for cleaning by machine sweeping of 35.6 cts. The city has 206,875 sq. yds. of improved pavements, which would cost \$73.65 to clean daily, or \$14,730 for a season of 200 working days, which is equivalent to 71 cts. per sq. yd. per year. This enormously high cost shows the usual low efficiency of men working by the day for a city.

Cost of Sweeping, Rochester, N. Y.—Mr. Edwin A. Fisher gives the following cost of sweeping for Rochester, N. Y., in 1901:

	No. times swept.	Per sq. yd. for year.
Asphalt streets	99	3.71 cts.
Brick	60	2.69 cts.
Medina stone block	101	5.27 cts.

It will be noted that, at this rate, each sweeping cost:

	Per 1,000 sq. yds.
Asphalt streets	37 cts.
Brick	47 cts.
Medina stone block	52 cts.

These high costs show poor efficiency of workmen.

These streets were sprinkled at a cost of 2.21 cts. per sq. yd., or \$250 per mile, during the year.

Cost of Street Sweeping, Albany, N. Y.*—The street cleaning of Albany, N. Y., is effected by three methods: Machine sweeping of improved streets; hand cleaning of cobblestone streets and alleys and hand cleaning in the business district. All of the work is done by city forces, and the city owns the sweeping machines and street sprinklers and hiring necessary teams and drivers.

In the principal business districts the asphalt pavements (173,000 sq. yds.) are kept cleaned and waste paper picked up. The following regular gang is employed for this work, the wages being \$1.75 per day:

2 men cleaning granite cross-walks	\$ 3.50
3 men cleaning asphalt	5.25
3 men picking up waste paper	3.50

Total daily expense

\$12.25

This is equivalent to an annual expense of \$4,100, or nearly 2.4 cts. per sq. yd., not including the additional cost of sweeping streets with machines.

*Engineering-Contracting, Dec. 4, 1907.

The cobblestone pavements, of which there is a total area of 229,229 sq. yds., are cleaned by hand hoes or broom, at the following daily expense:

1 foreman, at \$2.35.....	\$ 2.35
10 men, at \$1.75.....	17.50
1 horse and driver for sprinkler, at \$3.50.....	3.50
Total	\$24.35

The pavements are cleaned for a period of eight months at a total cost of about \$4,800, or 2.1 cts. per sq. yd. per year.

The principal part of the street cleaning work is effected by machine sweeping, the areas and kinds of pavement covered being as follows:

	Sq. yds.
Granite block pavements.....	560,623
Vitrified brick pavement	468,733
Sheet asphalt	173,094
Asphalt block	14,500
Total	1,206,950

This area is swept twice a week during eight months of the year, or from about April 1 to December 1. The force engaged in machine sweeping consists of four gangs, each under a foreman, and made up of 1 street sprinkler, 2 machine sweepers and 12 men. Each gang has its regular district to cover day or night as the case may be.

The sweeping is done in the usual manner, the pavements first being lightly sprinkled with water to lay the dust and then swept with the machines, the dirt being pushed by the latter from the center of the street to each of the gutters. The men then sweep the dirt into piles along the gutters at intervals of about 25 ft. Machine cleaning in the business district is done only at night.

The daily labor cost of sweeping and collecting the dirt in piles is as follows.

8 teams and drivers for 8 sweeping machines, at \$5.....	\$ 40.00
4 teams and drivers for 4 sprinklers at \$5.....	20.00
4 foremen, at \$2.35.....	9.40
48 men, at \$1.75	84.00
Total daily labor cost	\$153.40

The above force is employed about eight months, the total yearly expense for labor being about \$32,000. The cost of repairs to sweeping machines and sprinklers, cost of new brooms and refitting old brooms and other incidentals amounts to about \$4,000 per year, making a total cost of sweeping the dirt into piles amount to about \$36,000. As the total amount of pavement swept over each amounts to about 85,000,000 sq. yds., the cost of sweeping the dirt into piles is about 42 cts. per 1,000 sq. yds. for each sweeping. This does not include the cost of shoveling the dirt from the piles into wagons and conveying it to dumps or other places where it is used for filling. This work is done by contract, the price for 1907 being \$11,500.

There are 8 public dumps, which receive street dirt, ashes, etc.,

and are cared for by 9 men at an expense of \$15.76 per day, or about \$4,000 per year.

Since the 1,206,950 sq. yds. involve 85,000,000 sq. yds. of sweeping yearly, each street is swept about 70 times during the year.

Summing up we have the following cost of sweeping 1,206,950 sq. yds., not including the 229,229 sq. yds. of cobblestone pavement:

	Per year.	Per sq. yd. per year Cts.
Laborers cleaning business streets.....	\$ 4,100	0.34
Gangs with street sweeping machines.....	32,000	2.65
Repairs to sweeping machines, etc.....	4,000	0.33
Loading and hauling dirt to dumps (by contract) ..	11,500	0.95
Spreading dirt and ashes at dumps.....	5,000	0.42
Total	\$56,600	4.69

It should be remembered that the first item, "laborers cleaning business streets," costs 2.4 cts. per sq. yd. of business street cleaned, which becomes 0.34 ct. per sq. yd. of entire area of city streets.

Since the 8 machine sweepers sweep 85,000,000 sq. yds. in the working season (8 mos.), each machine covers 10,600,000 sq. yds. in the 210 working days, or 50,000 sq. yds. per day, at a cost of 38.4 cts. per 1,000 sq. yds. swept once. This is for labor alone, and, as will be seen from the tabulation of wages above given, more than 50% of this cost is for the wages of the laborers who sweep the dirt into piles in the gutters ready to haul away, there being 6 such men to each machine sweeper. This is an exceedingly high cost, but it does not include the excessive cost of repairs, etc., which is \$500 per year for each machine sweeper (plus half a sprinkler), etc., or nearly \$2.50 per working day, thus adding nearly 5 cts. per 1,000 sq. yds. swept.

Summing up we have the following total cost for sweeping 1,000 sq. yds. each time:

	Per 1,000 sq. yds. Cts.
Gang with street sweeper	38.4
Repairs to sweeper, etc.....	4.7
Loading and hauling dirt (by contract).....	13.6
Spreading dirt and ashes.....	6.0
Total	62.7

All of the last item is not properly chargeable to sweeping, since it involves spreading ashes also.

In excuse for these exceedingly high costs it has been said that a large part of the pavement is granite blocks and that the Albany streets are in many cases very steep, or hilly. This excuse is inadequate, for not half the streets are granite, and far less than half are steep. The true excuse is the general inefficiency of men working by the day for any municipality.

Cost of Street Flushing and Sweeping, St. Louis, Mo.*—The street cleaning of St. Louis is done by the day labor plan, six day

**Engineering-Contracting*, Jan. 15, 1908.

gangs and four night gangs being employed in the work. A gang comprises the following.

5 flushing machines at \$6.00.....	\$30.00
4 dirt wagons at \$4.50.....	18.00
6 laborers at \$1.50.....	9.00
1 inspector at \$3.00.....	3.00
Total	\$60.00

From 20 to 36 gals. of water are used for each square (100 sq. ft.) of flushing, or 2 to 3 gals. per sq. yd. The average cost to the city per great square (10,000 sq. ft.) for one flushing of the pavements in the business and residence districts is \$1.10, or \$1 per 1,000 sq. yds. This estimate is based upon the number of squares flushed per month, without regard to the paving material, or where the streets cleaned are located. It is possible to flush an asphalt pavement in the residential district for \$0.75 per great square, or \$0.70 per 1,000 sq. yds.; while the granite block pavements in the business district, where the delays are caused by traffic, may cost \$1.25 per great square, or \$1.22 per 1,000 sq. yds.

The average cost for machine broom sweeping is about \$0.50 per great square, or \$0.45 per 1,000 sq. yds., these machines being used on the brick pavements except where the streets are very dirty.

The block patrol system of cleaning is also employed. In this, one man is given about five city blocks to clean, the average length of block being 300 ft. With wages at \$1.50 and the width of roadway assumed at 36 ft., $5\frac{1}{2}$ great squares are cleaned each day at a cost of \$0.28 per great square, or \$0.25 per 1,000 sq. yds. The system of street sprinkling aids very much the cleaning of streets by the block system, as all of the paved streets are sprinkled from one to four times per day, the cost thereof being charged as a special tax against the property fronting the street sprinkled, the average rate for the year amounting to about \$0.04 per front foot.

The total mileage of hard pavements is as follows:

	<u>Miles</u>
Asphalt	45.43
Bituminous macadam	24.46
Vitrified brick	96.19
Granite blocks	63.48
Wood blocks	2.50
Total	332.06

In addition, 134 miles of improved alleys are cleaned from the appropriation for street cleaning.

It will be noted that all these costs are exceedingly high.

Life of Sweeping Machines.—In Berlin the life of horse-drawn sweeping machines (rotary brooms) has been about 20 years. A rotary broom lasts only 21 days when used every night; a machine requires 17 brooms yearly, and works 7 hrs. daily.

SECTION V.

STONE MASONRY.

Definitions.—Consult Section VI, on Concrete, for definitions not found in this section.

Abutment.—The foundation or substructure of a bridge. Abutments are built on the banks of a stream; piers are built in the stream itself.

Apron.—A covering over the earth or rock below the spillway of a dam.

Arch Culvert.—A culvert with an arched roof.

Arch Masonry.—That portion of the masonry in the arch ring only, or between the intrados and the extrados.

Ashlar.—First-class squared stone masonry dressed so that its joints do not much exceed $\frac{1}{2}$ -in. in thickness.

Azed.—Dressed so as to cover the surface of a stone with chisel marks which are nearly or quite parallel.

Back.—The rear face of a wall.

Backing.—The rough backing masonry of a wall faced with a higher class of masonry. The earth deposited back of a wall or arch is sometimes miscalled backing instead of backfilling or lining.

Barrel.—The under surface of an arch. See Soffit.

Bat.—A part of a brick or stone.

Batter.—The backward slope of the face of a wall. A 1-in. batter means that the face of the wall departs from a plumb line at the rate of 1 in. in every foot of rise.

Beds.—Or bed joints, the horizontal joints of masonry. See also "Natural bed."

Belt Course.—A projecting course of masonry immediately under the coping; a belt course is often called a corbel course. Its object is to give a better appearance to a wall.

Bench Wall.—The wall or abutment supporting an arch.

Blind Header.—A header that extends only a short distance back into a wall instead of extending to the full depth specified; blind headers are also called "bob-tails."

Block Rubble.—Large blocks of building stone as they come from the quarry. See Rubble.

Bond.—The arrangement of stones so as to overlap or "break joints."

Box Culvert.—A culvert having a waterway of rectangular cross-section.

Breast Wall.—A wall built against the face of an excavation to prevent its caving down; also called a face wall.

Bridge Seat.—See Pedestal.

Broken Range Masonry.—Masonry in which the bed joints are parallel but not continuous.

Build.—A vertical joint.

Bulkhead.—A head wall at the end of a culvert, and perpendicular to the axis of the culvert. See Head Wall.

Bush Hammer.—To dress stone with a hammer having a number of pyramidal cutting teeth on its striking face.

Buttress.—A vertical piece of masonry projecting from the face of a retaining wall to strengthen it.

Centers.—The temporary structure that supports an arch during its construction. (Also called Centering.)

Chisel Draft.—A narrow plane surface cut with a pitching chisel along the outer edges of the face of an ashlar stone, usually cut the width of the chisel.

Classes.—Different kinds of masonry specified, usually, first, second and third class; the first class being the most expensive. What is "first class" according to one engineer may be "second class" according to another.

Closer.—A narrow stone used to finish a course of masonry.

Coping.—The top course of stones on a wall, usually made of large flat stones which are laid so as to project a few inches over the face of the wall. A projecting coping relieves the wall of a "bobtailed" appearance.

Course.—A horizontal layer or tier of stones. "Coursed masonry" is built up in courses.

Course Bed.—Stone, brick or other building material in position, upon which other material is to be laid.

Cover-Stones.—The flat stones forming the roof of a box culvert.

Cramp.—A bar of metal having the two ends bent at right angles to the bar for insertion into holes drilled in adjoining blocks of stone.

Crandall.—A stone dressing hammer, consisting of a steel bar with a slot in one end holding 10 double-headed points of steel ($\frac{1}{4}$ -in. square x 9 ins. long), producing an effect like fine pointing.

Crown.—The top of an arch at its highest point.

Cell.—A rejected stone or brick.

Culvert.—A waterway under a road, canal or railroad embankment.

Cut-Stone.—A stone that is carefully "dressed" or shaped with tools.

Cut-Water.—The upper wedge-shaped end of a bridge pier.

Cyclopean Masonry.—Masonry made of huge stones, usually bedded in concrete.

Damp-Course.—A waterproofed course or bed joint in a wall, usually just above the surface of the ground; its purpose being to prevent the rise of water in the pores of the stone and mortar due to capillary action.

Depth.—The width of a stone measured perpendicularly to the face of the wall; the distance that a face stone extends into the wall.

Dimension Stone.—Stone dressed to exactly specified dimensions.

Dirt Wall.—See "Mud Wall."

Dog Holes.—Shallow holes drilled in a stone to afford a bite for the "dogs," or hooks, used in lifting the stone with a derrick.

Dowel.—A short steel pin inserted part way into the adjoining faces of two blocks of stone.

Draft Line.—See "Chisel Draft."

Drafted Stones.—Stones on which the face is surrounded by a draft, the space inside the draft being left rough.

Dress.—To cut or shape a stone with tools.

Drove.—Dressed on the face so as to have a series of small parallel ridges and valleys.

Dry Wall.—A stone wall built without mortar.

Efflorescence.—A white crust that often forms on the face of masonry, due to the leaching of soluble salts out of the mortar; often called "whitewash."

Expansion Joint.—A vertical joint or space to allow for temperature changes.

Extrados.—The curve that bounds the outer extremities of the joints between the arch stones, or voussoirs.

Face.—The front surface of a wall.

Face Stones.—The stones forming the front of a wall.

Face Wall.—See "Breast Wall."

Fine Pointed.—Dressed by fine point to smoother finish than by rough point.

Flush.—(Adj.) Having the surface even or level with an adjacent surface. (Verb.) (1) To fill. (2) To bring to a level. (3) To force water to the surface of mortar or concrete by compacting or ramming.

Footing Courses.—The bottom or foundation courses, which usually project beyond the "neat work" of an abutment.

Foundation.—(1) That portion of a structure, usually below the surface of the ground, which distributes the pressure upon its support. (2) Also applied to the natural support itself; rock, clay, etc.

Foundation Bed.—The surface on which a structure rests.

Frost Batter.—A batter occasionally given to the rear of a wall near its top to prevent the dislocation of the top course of stones upon the formation of frost in the ground.

Full-Centered.—An arch that is a full semi-circle, or half circle.

Groin. The curved intersection of two arches meeting at an angle.

Grout.—A thin watery mortar which is poured into the joints after the stones have been laid.

Haunch.—The part of an arch between the crown and the skew-back.

Header.—A stone laid with its longest dimension perpendicular to the face of the wall.

Head Wall.—An end wall, or bulkhead, of a culvert.

Hollow Quoin.—The vertical semi-circular groove in the masonry into which fits the "quoin post," or hinge post, of a canal lock gate.

Intrados.—The inner circle of an arch.

Joint.—The space between adjacent stones; sometimes the word joint is used to denote the vertical joints only, in distinction from the "beds" or bed joints. Joints are usually filled with mortar.

Keystone.—The center stone at the crown of an arch.

Lagging.—The sheeting plank placed upon the ribs of arch centers.

Length.—The longest dimension of a stone.

Leveler.—A small rectangular stone, not less than 4 to 6 ins. thick, used in broken range work to complete the bed for a stone in the course above and give it proper bond. Sometimes called jumper or dutchman.

Lewis Hole.—A wedge-shaped hole in a block of stone, made for the purpose of lifting the block by the aid of a lewis.

Lining.—The gravel or broken stone filling back of a slope wall or retaining wall, for the purpose of drainage and to protect the earth from wash.

Lock.—Any special device or method of construction used to secure a bond in the work.

Mortar.—A mixture of sand with cement (or lime) and water. A 1:2 (one to two) mortar contains 1 part cement and 2 parts sand.

Mud-Wall.—A small parapet or retaining wall built on top of a bridge abutment to prevent the earth backfill from sliding or washing down upon the coping.

Natural Bed.—A laminated or stratified stone is laid in its "natural bed," or "quarry bed," when its laminations are horizontal or are perpendicular to the load that they carry. Granite has no "natural bed."

Neat Mortar.—Mortar made without sand.

Neat Work.—That part of an abutment above the footing courses, which is generally equivalent to saying, that part above the surface of the ground or water.

Nigged.—Hewed with a pick.

Niggerheads.—Rounded cobble stones.

Parapet.—The "mud-wall" of a bridge abutment; the "bulkhead" of a culvert; the spandrel wall at each end of an arch bridge or culvert, but more properly the extension of the spandrel wall above the crown of the arch; a low guard wall rising above the surface of a roadway or walk to prevent pedestrians or vehicles from leaving the roadway or walk.

Patent Hammer.—A double-faced hammer so formed as to hold at each face a set of wide thin chisels for giving a finish to a stone surface.

Paving.—Regularly placed stone or brick forming a floor.

Pedestals.—Or pedestal blocks, are stone blocks on top of an abutment coping; the pedestal blocks receive the weight of the bridge, and are often called "bridge seats"; the term pedestal is

also applied to a small masonry pier upon which the post or sill of a trestle rests.

Perch.—16½ cu. ft. in most parts of the United States; in some places 22 cu. ft.; and rarely 24½, which was the old-fashioned perch.

Pier.—A masonry structure built to support a bridge, between the abutments; a column supporting two sequent arches. See "Abutment."

Pilaster.—A square pillar projecting from the face of a wall to the extent of one-quarter to one-third its breadth.

Pinser.—A spall or small stone used to wedge up a stone and give it better bearing.

Pitch-Line.—A well defined, straight line cut along the edge of a quarry-faced stone, but not as wide as a chisel draft.

Pitched-Face.—A face roughly dressed with a pitching chisel.

Plug and Feathered.—Split with plug and feathers; the plug being a small wedge of steel driven between two pieces of half-round steel, called feathers, which bear against the sides of the drill hole.

Pointing.—A superior class of mortar used to fill the joints in the face of a masonry wall for a depth of 1 to 3 ins.

Quarry Faced.—A rough face of stone, only the larger projections having been knocked off with a hammer.

Quoin.—See "Hollow Quoin."

Raising Stone.—See "Pedestal."

Ramp Wall.—The wing of an abutment, often called a ramp.

Random.—Not coursed.

Range Masonry.—Masonry in which the various courses are laid up with continuous horizontal beds.

Ranged.—Laid in a course of the same thickness for its full length; broken ranged masonry is laid in courses not of uniform thickness throughout each course.

Retaining Wall.—A wall that receives the horizontal thrust of earth back of it; on canal work such walls are called "vertical walls" to distinguish them from slope walls.

Ring-Stones.—The voussoirs that form the end faces of an arch, as distinguished from the "sheeting stones" that form the body of the arch.

Rip-rap.—Large stones thrown in at random to protect earth from scour by currents or waves; occasionally called "random stones." The term "hand placed rip-rap" is sometimes used to denote rough slope wall, but slope wall is a preferable term.

Rise.—The thickness (or vertical height) of a stone, measured from its lower bed to its upper bed. Do not confuse the "rise" with the "depth." The rise of an arch is the vertical distance from the spring line to the under face of the keystone.

Rock-faced.—See "Quarry-faced."

Rock-fill Dam.—A dam made of dry masonry; a rubble dam in which no mortar is used.

Rubble.—Masonry made of stones that have not been dressed.

or if dressed at all, have been only roughly shaped with a hammer, or "scabbled."

Scabbled.—Hammer dressed.

Sheeting.—The stones forming an arch. See "Ring-Stones."

Skew Arch.—An arch the plane of whose ring-stone faces forms an angle of less than 90° with the axis of the barrel. If the sheeting stones are all cut skewed, the arch is a "true skew"; but if only the faces of the ring-stones are cut on a skew, while all the other sheeting stones are cut with end joints perpendicular to the bed joints, the arch is called a "false skew."

Skewbacks.—The course of stones against which the springer stones of an arch abut.

Slope Wall.—A pavement of scabbled stones laid upon an earth slope to protect it from wash. If the stones are not scabbled, the terms rip-rap, or hand-laid rip-rap, are more appropriate.

Soffit.—The under surface of an arch.

Span.—The shortest distance between the spring lines of an arch.

Spandrel.—The triangular area bounded by the extrados of an arch, a horizontal line tangent to the extrados at the crown and a vertical line through the springing. A spandrel wall is a wall built on the extrados and filling the spandrel area; it is often mis-called a parapet wall. Spandrel filling is the earth filling between the spandrel walls.

Spall.—A fragment of stone, or stone chip.

Springers.—The lowest course of arch stones, the course resting on the skewbacks.

Springing.—Or spring line, the inner edge of the skewbacks, or the lower edge of the springers.

Squared-Stone Masonry.—Masonry in which the stones are roughly squared and roughly dressed on beds and sides.

Starlings.—The two ends of a pier.

Stretcher.—A stone laid so that its longest face forms part of the face of a wall.

Vousoir.—An arch stone.

Wing.—A spur wall at the end of a bridge abutment; also called a ramp.

Note.—Other definitions will be found at the beginning of the section on Concrete.

Percentage of Mortar in Stone Masonry.—Published tables giving the percentages of mortar in different kinds of masonry have been very misleading not only because they have been based upon meager data, but because the factors that cause variations in mortar percentages have not been discussed.

There are two ways of estimating the amount of cement required per cubic yard of masonry: (1) By estimating the percentage of mortar in the cubic yard of masonry, and then using a mortar table like that on page 252. (2) By tabulating the different kinds of masonry and giving the fractions of a barrel of cement required for a cubic yard of each kind of masonry, when the mortar is a 1:3 mixture, also when it is a 1:2 mixture—these two being the com-

mon mixtures. Each method possesses its advantages, but the first is the safest because proper allowance can be made for variations in the size of cement barrel.

A great many masonry walls consist of a "facing" of ashlar, or squared stone cut to lay close joints, and a "backing" of more or less irregular rubble stones. Obviously, if the wall is a thin one, the percentage of backing is much smaller than if the wall is thick. So that it would be desirable always to keep separate records of the amount of mortar used for the backing and for the ashlar. In practice, however, it is usually impracticable to keep separate records. The final record usually gives only the amount of cement per cubic yard of the whole wall. However, in making close estimates of probable cost it is well to keep the two classes of masonry distinct.

Knowing the average size of cut stone blocks and the thickness of joints specified, we can estimate the per cent of mortar for the face stone with considerable accuracy. Suppose the cut stone is to be in courses 12 ins. high, and dressed to lay $\frac{1}{2}$ -in. joints for 12 ins. back of the face. We can assume that the length of each face stone will not be far from $1\frac{1}{2}$ times its thickness, or 18 ins. in this case. Hence each cut stone will contain $1 \times 1 \times 1\frac{1}{2}$, or $1\frac{1}{2}$ cu. ft. Each stone must have one end and one bed mortared to a thickness of $\frac{1}{2}$ in., hence we have: $1 \times 1\frac{1}{2} \times (\frac{1}{2} \div 12)$, or 0.04 cu. ft. of mortar for the end; and $1 \times 1\frac{1}{2} \times (\frac{1}{2} \div 12)$, or 0.05 cu. ft. of mortar for the bed; making a total of 0.1 cu. ft. of mortar for the end and bed of each stone. But as each stone contains 1.5 cu. ft., we see that $0.1 \div 1.5$ gives us 7% (nearly) of mortar for the cut stone.

Obviously the larger the individual stones the less is the percentage of mortar. Stones 18 ins. high, 30 ins. long, and dressed to lay $\frac{1}{2}$ -in. joints for 18 ins. back of the face, require $4\frac{1}{2}$ % of mortar.

The mortar required for the back of the stone is apparently omitted in applying the above method, but it is not omitted in the final account, since it is included in the rubble backing to a consideration of which we now pass.

Rubble is a term having wide variations in meaning, but in general it may be said to apply to masonry built of undressed stones just as they come from the quarry. Now, if the quarry is limestone or sandstone yielding flat-bedded stones, the rubble may be laid with bed joints as close as the joints of well-dressed granite ashlar. On the other hand, if the quarry is granite or rock that when blasted yields chunks of irregular shape, the rubble becomes a sort of giant concrete and requires a large percentage of mortar to fill its voids.

In any kind of rubble the percentage of mortar can be considerably reduced by packing spalls into the vertical joints between adjacent stones. As Portland cement mortar seldom costs less than \$6 per cu. yd., and as spalls usually cost but a few cents per cu. yd., no pains should be spared to use as many spalls as the joints will hold.

If no spalls are used, and if the rubble is made of irregular stones,

about 25% of the rubble masonry is mortar. If the rubble is made of flat-bedded sandstone or limestone, it may contain as low as 15% mortar, but more often will average 20 to 25%.

The following are records of the actual amounts of mortar used in different masonry structures:

(1) The Medina sandstone retaining walls on the Erie Canal averaged about 10 ft. high and were faced with hammer-dressed stones and backed with flat-bedded rubble. About 22% of the wall was mortar. The mortar was 1:2, and it required about 0.63 bbl. cement per cu. yd. of wall. A barrel was counted as holding 3.8 cu. ft.

(2) Mr. A. J. Willey states that in the Crow Creek Dam, near Cheyenne, Wyo., there are 14,420 cu. yds. of rubble masonry, of which 34% was mortar. About 80% of this mortar was 1 Portland cement to 4 sand; the rest was 1 to 3. Each barrel was counted as 4 cu. ft., and 3,844 bbls. were used, or 0.63 bbl. per cu. yd.

(3) The Cheesman Dam is of rubble, with one ashlar face, and is said to contain 28% mortar.

(4) The Cheat River Bridge, on the B. & O. R. R., near Uniontown, Pa., has five piers and two abutments. The masonry is a first-class sandstone facing with a rubble backing of heavy stones, and the mortar was 1 of Louisville (natural) cement to 2 of sand. There were 3,710 cu. yds. of masonry, which required 1,500 bbls. of cement (shipped in bags), or 0.4 bbl. per cu. yd.

(5) The masonry locks on the Great Kanawha River, West Virginia, were built of sandstone obtained at Lotter, W. Va. Face stones were cut to lay $\frac{1}{4}$ -in. bed-joints and 1-in. vertical joints. Backing bed-joints were 1 in. The mortar was 1 part Rosendale cement (Hoffman brand), to 2 parts sand. It required 0.36 bbl. per cu. yd. of masonry.

(6) A curved masonry dam, 82 ft. high, built at Remscheid, Germany, is made of slate having a specific gravity of 2.7. The masonry, laid in trass mortar, weighs 4,015 lbs. per cu. yd. Owing to the irregular form of the stones the mortar was 38% of the masonry.

(7) The Holyoke Dam, 30 ft. high, is of rubble masonry with a cut granite face. The mortar was 1 Portland cement to 3 sand, and it is stated that 0.87 bbl. of cement was required per cubic yard of rubble masonry.

(8) Masonry in bridge piers, at Van Buren, Arkansas River, was for the most part of white limestone. In 10 piers there were 4,500 cu. yds. of masonry, which averaged 0.57 bbl. natural cement per cu. yd. The beds and joints were 1:2 mortar, and a 1:1 grout was also used.

(9) The limestone masonry for the Sault Ste. Marie locks (U. S. Government) amounted to 80,876 cu. yds., of which 28% was cut stone, 60% backing and 17% mortar. The cut stone blocks average 1.3 cu. yds. each and were dressed to lay $\frac{1}{4}$ -in. vertical joints for 18 ins. back of the face, and the bed joints were dressed to $\frac{1}{4}$ in.

the full depth of the stone. In cutting the stone there was a wastage of 25½% of stone. The mortar was 1:1, and it required 0.29 bbl. of Portland cement per cu. yd. of cut stone, 1.21 bbls. of natural cement per cu. yd. of backing, and 0.78 bbl. per cu. yd. of the wall, including cut stone and backing. The backing stones each averaged 8 sq. ft. bed area, and no bed-joint was greater than 1 in.; and no vertical joint exceeded 4 ins., the average being 2 ins. This is remarkably close jointing for backing, and was unquestionably very expensive to secure.

(10) The Lanchensee Dam, Germany, was made of graywacke rubble (stones ½ to ¾ cu. yd. each); 35% of the dam was mortar. A force of 45 masons, 12 helpers, 27 laborers and 4 foremen worked on the dam, and 110 men at the quarry. They averaged 120 cu. yds. of masonry per day, the best day's work being 196 cu. yds. Eight locomotive cranes running on trestles took the stone from the cars. The work was done by day labor for the German Government.

(11) The Sweetwater Dam, California, was built of a granitic rubble that was quarried in irregular chunks. Mortar was 1:3, proportioned by barrels, and it required 0.84 bbl. cement per cu. yd. of rubble masonry.

Cost of Laying Masonry.—According to my experience on numerous small culvert bulkheads made of limestone or sandstone rubble, one mason with a helper to mix mortar and "get stone" will lay 4 to 5 cu. yds. per 8-hr. day. If mason's wages are \$3 and helper's \$1.50 this makes the cost average \$1 per cu. yd. for laying. No derrick is used in such work the stone being one-man or two-man stone. Moreover, the stone requires little or no hammer-dressing on the part of the mason.

In laying dry slope-walls (12 or 15 ins. thick) where stone of the same kind as the above is used, requiring very little hammer-dressing, a slope-wall mason will lay 5 to 7 cu. yds. per 10-hr. day, and I have had a man lay as high as 12 cu. yds. per day. One laborer to about 2 or 3 slope-wall masons is required, to furnish them with stone. A common laborer will lay about half as many yards of slope-wall stone as a skilled mason, so there is little or no economy in using unskilled labor in laying the stone that must be laid to a line and occasionally dressed with a hammer.

On a highway arch bridge of 30-ft. span, with a barrel 20 ft. long, there were 50 cu. yds. of cut stone sheeting, 30 cu. yds. of cut stone facing in the abutments and walls, and 180 cu. yds. of limestone rubble in the abutments and walls. The masonry was laid by a mason and 3 laborers, two of the laborers operating a hand power derrick and getting stone for the mason, while the third laborer made mortar and also assisted in getting stone. This gang worked without a foreman and were very slow, since they averaged only 3 cu. yds. per 8-hr. day. With mason's wages at \$3 and laborers' at \$1.50, the cost of laying the masonry was \$2.50 per cu. yd. This included the erecting of two small derricks on opposite sides of the stream, but did not include erecting the centers for the arch. On page 286, the cost of laying the masonry of an arch bridge, similar

to this one is given in detail; it being \$1.35 per cu. yd., which shows how easy it is to reduce the cost of laying where the men are better organized. The common mistake made in organizing forces for laying stone with hand operated derricks is in having too many laborers to one mason, who is unable to keep them busy.

If the mason must hammer-dress the stone to a great extent, as is often required by inspectors on granite rubble arches, the cost of laying (including this hammer dressing) may amount to \$3.50 per cu. yd. It is difficult to be definite in the matter of costs of hammer-dressed granite rubble, because inspectors vary so extremely in their interpretation of specifications. If no hammer-dressing is required (and none should be required for backing laid in cement mortar), the cost of laying granite rubble need not exceed the cost of laying limestone or sandstone rubble, say \$1 per cu. yd., wages being as above given.

In tearing down and relaying an old masonry retaining wall (9 ft. high), the author employed 16 laborers and 2 masons under a foreman. A stiff-leg derrick having 30-ft. boom, and operated by hand, was used to handle the heaviest stones. Much of the backing was laid by hand by the laborers. This gang averaged 36 cu. yds. of masonry laid per 10-hr. day, at a cost of \$30, exclusive of foreman's wages, or less than 85 cts. per cu. yd. It cost 75 cts. per cu. yd. to tear down the wall before relaying it.

For laying any considerable quantity of masonry, never use a hand-operated derrick. A horse-whim forms cheaper power than two men on a winch. But in either case the lost time of swinging, or slewing, the boom cannot be avoided. The men (usually two) who swing the boom are called "tag men," because they pull the boom back and forth with "tag ropes." The wages of these men form a surprisingly large part of the cost of laying stone where a derrick is used which is not provided with a "bull-wheel" for swinging the boom. The engineman controls the swinging of the boom where a bull-wheel is used, and can make a swing of 90° in 15 to 20 seconds.

To show how rapidly stone may be handled with a 60-ft. boom derrick, the following record will serve:

	Seconds.
Hooking on to skip.....	35
Swinging boom 90°.....	20
Dumping skip.....	15
Swinging back 90°.....	20
Total	90

This is equivalent to 400 skip loads in 10 hrs.; and, were the material supplied and removed fast enough, the derrick could readily maintain this output for 10 hrs., handling 1 cu. yd. of rubble in each skip load. Obviously in masonry work, where a bull-wheel derrick is used, the limiting factor is the amount of stone the masons can handle per day. Much of the derrick time is spent in the puttering work necessary in carefully placing large stones in the wall. Now, where tag-rope men are used instead of a bull-wheel, prac-

Usually all their time is wasted, as they spend so little of the day doing active work.

Further data on the cost of laying masonry will be found on subsequent pages.

Estimating the Cost of Stone Dressing.—Stone may be divided into two classes: (1) Stone stratified in beds of a thickness not much exceeding 30 ins.; and (2) stone that is either unstratified, or occurs in beds of such thickness that the blocks must be split with plugs and feathers to secure sizes which can be handled with a derrick.

Many sandstones and limestones occur in thin strata or layers, and, after the use of a little black powder to "shake up" the ledge, it is possible to quarry blocks with wedges and bars. These blocks will often be as smooth as a floor on the bed-joints, but may be quite irregular on the vertical joints. However, either by hammering, or by plug and feathering, the vertical joints can be squared up at slight expense ready for further dressing if required by the specifications. On the other hand, all granites and many thick-bedded limestones and sandstones, break out in such irregular shapes that it often happens that every face must be plug and feathered before the block is roughly squared up ready to be dressed by the stonecutters. Obviously the dressing of the beds of such stones is far more expensive than the dressing of the beds of smoothly stratified stones.

Besides differences in hardness, we see that the shape of the stones as they come from the quarry is a very important factor in the cost of dressing.

Another factor of scarcely less importance is the size of the blocks of stone. It is generally possible to quarry granites in blocks of any desired size, the limit being fixed by the strength of the derricks and other machinery used. A very common size of granite blocks dressed ready to lay in the wall is 18 ins. rise x 40 ins. length x 24 to 30 ins. depth. And as every block of granite must be plug and feathered to size before dressing, it is just as cheap to make coursed ashlar as random range ashlar. On the other hand, stratified rocks like sandstone usually occur in layers of different thickness, and it may be impossible to secure enough stone for courses of a specified rise without wasting a large part of the quarry product. An engineer should never specify any given "rise" for the courses (except in granite), until he has examined the quarries and is sure that they will yield the product specified. But engineers often fail to do this, and the contractor must be careful not to be equally foolish in failing to examine the stone available.

Stone is often so seamy or so crittle that it can be quarried only in small chunks. Now it is obvious that the smaller the chunk the greater the area that must be dressed per cubic yard; but how greatly this factor affects the cost of dressing is seldom considered. To illustrate, let us assume that blocks for ashlar are each 12 ins. rise x 24 ins. long x 18 ins. deep. Each block then contains

2 cu. ft., and has 6 sq. ft. of bed joints and 3 sq. ft. of end joints, or 9 sq. ft. of joints to be dressed. Let us now take an ashlar block 18 ins. rise x 36 ins. long x 24 ins. deep. This block contains 9 cu. ft., and has 12 sq. ft. of bed joints and 6 sq. ft. of end joints, or 18 sq. ft. of joints to be dressed. With the smaller block we have 9 x 9, or 81 sq. ft. of joints to be dressed for every cubic yard; whereas with the larger block we have 3 x 12, or 36 sq. ft. to be dressed for every cubic yard. In other words the cost of dressing ashlar of the 3-cu. ft. blocks is more than twice as expensive per cubic yard as the cost of dressing the 9-cu. ft. blocks.

It is apparent, therefore, that all records of the cost of dressing stone should be expressed in terms of the square feet actually dressed, and then the data can be applied to blocks of any given size to obtain the cost of dressing per cubic yard. This method of estimating costs will often lead a contractor to import his stone a long distance by rail rather than attempt to dress the small-sized stones from local quarries.

It is customary among contractors and stonecutters to speak of so and so many "square feet" of stone dressed per day, meaning not the number of square feet of beds and joints dressed, but the square feet of "face." For example a stone is $1\frac{1}{2}$ ft. rise x 3 ft. long x 2 ft. deep. This stone when laid lengthwise in the face of a wall will show a face area of $4\frac{1}{2}$ sq. ft., and the stone cutter is said to have dressed $4\frac{1}{2}$ sq. ft. As a matter of fact he has dressed 12 sq. ft. of bed joints, and 6 sq. ft. of end joints, beside plugging off or hammering the face of the stone, and cutting the drafts if specified. In my early work I was misled by this method of estimating stone dressing in terms of the square feet of face. It is a method that should be abandoned.

Data of the actual cost of stone dressing will be given in subsequent pages.

Data on Stone Sawing.—There is little on this subject in print, but in almost any large city stone saws may be seen at work, and a rough estimate can be made of the cost of stone sawing. To tell how many inches deep a saw cuts in a day, examine a slab of stone newly cut in the yard. It will be noted that there are rust lines on the face of the slab. The distance between these lines indicates the depth cut in a day, for when the saws are idle at night, the rust forms.

For cutting stone into thin slabs, it is common practice to run two "gangs" of saws, of 15 saws in a "gang" driven by a small engine. As nearly as I have been able to estimate by observation and inquiry, the daily cost of operating a "two-gang" plant is as follows per 9-hr. day in New York City:

1 gangman	\$ 4.00
1 helper	2.00
2 cu. yds. sand, at \$3.....	6.00
$\frac{1}{2}$ ton coal, at \$6.....	3.00
Total per day	\$15.00

Working in Tennessee marble each saw cuts about 6 ins. deep per day, therefore, if the block is 6 ft. long, the 80 saws cut 96 sq. ft. per day of 9 hrs. The cost of sawing slabs, therefore, approximates 17 cts. per sq. ft. The saw cuts a kerf $\frac{1}{8}$ -in. wide.

I am told that with wages of polisher at \$3.50, slabs can be polished by hand at 6 cts. per sq. ft.; but where the polishing is done by machine the cost is about $2\frac{1}{2}$ cts. per sq. ft.

Wages of stone yard men in New York City are about a third higher than in most other American cities.

Mr. R. J. Cooke states that the rates of sawing different kinds of stone are as follows:

	Depth cut in 10 hrs., ins.
Granite, Addison, Me. (shot).....	10
Granite, Chester, Mass. (sand).....	12
Granite, Red Beach, Me. (shot).....	7 $\frac{1}{2}$
Bluestone, Hudson River (sand).....	8
Marble, Carara, Italy (sand).....	15
Marble, Tennessee (sand).....	9
Marble, Tate, Ga. (sand).....	6
Marble, Tate, Ga. (sand).....	12
Marble, Gouverneur, N. Y. (sand).....	12
Marble, W. Rutland, Vt. (sand).....	20
Marble, Proctor, Vt. (sand).....	15
Limestone, New Point, Ind. (sand).....	10
Limestone, New Point, Ind. (sand).....	15
Oolitic limestone, Bedford, Ind. (sand).....	40
Oolitic limestone, Bedford, Ind. (sand).....	70

Sandstone, N. Amherst, O. (sand).....	40
Sandstone, Clarksville, O. (sand).....	36
Brownstone, Portland, Conn. (shot).....	20
Brownstone, Hummelston, Pa. (shot).....	25

The Young & Farrell Diamond Stone Sawing Co., of Chicago, classifies stone into soft, medium and hard; soft includes sandstones; medium includes limestones, and hard includes marbles and granites. They say (1890) the cost of sawing per sq. ft. is: Soft, 8 to 10 cts.; medium, 13 to 17 cts.; hard, 25 to 30 cts.; all on the basis of 4-in. sawing or two cuts to the cubic foot. With wages of stone cutters at 50 cts. an hour, the cost of hand dressing the same classes of stones is given as follows per square foot: Soft, 25 to 30 cts.; medium, 40 to 45 cts.; and hard, 75 to 80 cts.; all clear face work.

Cost of Stone Dressing.—In addition to the data just given, The Syenite Granite Co., of Graniteville, Mo., say (1890) that the cost of hand dressing 36,000 cu. ft. of granite to $\frac{1}{8}$ -in. joints was 20 cts. per sq. ft., not including blacksmithing, handling, etc., which was 6 cts. more per sq. ft. This stone was granite cut to lay in 24 to 30-in. courses for the Merchants' Bridge, St. Louis, and it was delivered for \$1.15 per cu. ft.

The Kankakee Stone & Lime Co. say (1890) that, with wages at \$3 a day, the cost of dressing limestone (bush-hammered or drove-work) is 25 cts. per sq. ft.

Cost of Cutting Limestone and Sandstone.—In dressing Medina

sandstone, a stonecutter will dress enough stone in 9 hrs. to lay 12 sq. ft. of face in a wall having courses that average 15 ins. rise, which is equivalent to about 0.9 cu. yd. of face stone per day, or 30 sq. ft. of beds and joints cut to lay $\frac{1}{2}$ -in. joints for at least 12 ins. back of the face. The face is rock-faced, and is plugged off by the stonecutter.

In dressing limestone for arch sheeting, the author made the mistake of using a quarry whose product was all small and gnarled stones. Each stone after dressing averaged only 11 ins. thick, 22 ins. long, and 18 ins. deep, or about 0.1 cu. yd. per stone, so that to secure 1 cu. yd. of this cut-stone required the dressing of 80 sq. ft. of beds and joints. Each stonecutter averaged 36 sq. ft. of beds and joints (dressed to lay $\frac{1}{2}$ -in.) per 9-hr. day, or 1 cu. yd. in $2\frac{1}{4}$ days. These cutters received 40 cts. per hour.

Cost of Sandstone Bridge Piers.—The cost of cutting 246 cu. yds. sandstone to $\frac{1}{2}$ -in. joints for bridge piers was \$2.65 per cu. yd.; the cutting of the stones for the nose of the pier cost \$3 per cu. yd. The wages of cutters were 38 cts. per hr.

The cost of loading the stone, train service, sand, cement and laying the masonry was \$3.60 per cu. yd. About $\frac{1}{4}$ bbl. of Portland cement costing \$2.40 per bbl. was used per cu. yd. of masonry. The cost of quarrying the stone was \$1.65 per cu. yd. The total cost of the pier masonry was \$9 per cu. yd. For the foregoing data I am indebted to Mr. C. R. Nehr.

Cost of Cutting Granite for a Dam.—In building a dam in the northern part of New York state, the author used a granitic rock. The face stones were cut to lay in courses with beds and joints $\frac{3}{4}$ in. thick. Each cut stone was quarry-faced and averaged $1\frac{1}{2}$ ft. rise x 3 ft. long x 2 ft. deep, or about $\frac{1}{4}$ cu. yd. A stonecutter averaged one such stone per 8-hr. day, or 18 sq. ft. of beds and end joints dressed per day. A blacksmith, at \$2.50, and a helper, at \$1.50, sharpened the points and plug drills for 8 stonecutters. The cost of cutting this face stone was as follows:

	Per cu. yd.
Stone cutters, at \$4 per 8 hrs.	\$12.00
Blacksmithing	1.20
Labor banking stones and plugging off faces...	1.80
Sheds and tools.....	0.80
Superintendence	1.20
Total	\$17.00

On a small portion of the work the stone was dressed to lay $\frac{1}{4}$ -in. joints, which added \$6 per cu. yd. to the cost.

Cost of Cutting Granite, New York City.—Mr. Wm. W. MacLay gives the cost of cutting 2,065 cu. yds. of granite by a force of 40 stonecutters working for the New York Department of Docks, during 1873 to 1875. The working day was 8 hrs. The following table gives the average day's work of a stonecutter working for the Dock Department as compared with work done for contractors in New York:

	Sq. ft. per 8-hr. day.	
	For Dock Dept.	For Contractors.
Cutting Granite.		
Dressing beds and joints ($\frac{1}{4}$ in.).....	13.5	16.0
Pointed work with $1\frac{1}{2}$ -in. chisel draft all around	8.5	10.0
Pean-hammered	6.0	7.25
6-cut patent hammered.....	5.25	6.15
8-cut patent hammered.....	4.25	5.00

It will be noted that the men working for the Dock Department did about 15% less work daily than is said to have been the average under contractors.

In doing this dock work there were 1,524 cu. yds. of dimension stones cut into headers and stretchers. The headers averaged 3 ft. on the face by 3 ft. deep; and the stretchers averaged 8 ft. long on the face by 3 ft. deep; the rise being 20, 22 and 26 ins. for the different courses. The stones were cut to lay $\frac{1}{4}$ -in. beds and joints, the faces being pointed work with a $1\frac{1}{2}$ -in. chisel draft all around. The cost of this cutting was as follows:

	Per cu. yd.	Per cent.
Cutting (4.53 days)	\$13.23	48
Labor rolling stones.....	8.26	30
Sharpening tools	4.13	15
Superintendence	1.38	5
New tools and timber for rolling stones.....	0.28	1
Interest on sheds, derrick, and railroad.....	0.28	1
Total	\$27.55	100

In addition to this work there were 310 cu. yds. of coping cut to lay $\frac{1}{4}$ -in. joints, pointed on the face and with a chisel draft, 8-cut patent-hammered on the top, and with a round of $3\frac{1}{2}$ -in. radius. The coping stones were 8 ft. long, 4 ft. wide, and $2\frac{1}{2}$ ft. rise. The cost of cutting this coping was as follows:

	Per cu. yd.	Per cent.
Cutting (6.26 days)	\$18.27	48
Labor rolling stones.....	11.43	30
Sharpening tools	5.71	15
Superintendence	1.90	5
New tools and timber.....	0.38	1
Interest on sheds, etc.....	0.38	1
Total	\$38.06	100

It would appear from the above that the stonecutters received \$3 for 8 hrs., but Mr. MacLay states that the pay was \$4 for 8 hrs. If so there is some error in the other items, which I have calculated from the percentages given by him. It is difficult to understand how the "labor of rolling stones" could have been 30% of the total cost of cutting, unless the laborers assisted in plug and feathering the stones preparatory to cutting. The cost of tool sharpening (15%) was also very high. Certainly these two items were much higher than they would have been under a contractor.

Mr. J. J. R. Croes states that in cutting granite for the gate-houses of the Croton Reservoir at 86th St., New York, in 1861-2, the least day's work was fixed at 15 sq. ft. of beds and joints. This included the cutting of a chisel draft around the face of the stone, the cost of which was about one-fourth as much as cutting a square foot of

joint, making the actual least day's work equivalent to 17.7 sq. ft. of beds and joints cut. With wages of stonecutters assumed at \$3 per day, from the percentages given by Mr. Croes, I have calculated the cost of cutting to have been as follows per square foot:

	Per sq. ft.
Cutting (15 sq. ft. per day).....	\$0.200
Sharpening tools	0.022
Labor moving stone in yards.....	0.020
Drillers plugging off rough faces.....	0.008
Superintendence	0.016
Sheds and tools.....	0.014
Total	\$0.280

The cost of all the items other than the wages of stone cutters was 40% of the wages of the stonecutters, or 8 cts. per sq. ft.

Cost of Quarrying, Cutting and Laying Granite.—Mr. J. J. R. Croes gives the following data relative to work done on the Boyd's Corner Dam, near New York City:

The stone is a gneiss that is about as difficult to quarry as granite. The face stone for the dam average 1.8 ft. rise, 3.6 ft. long and 2.7 ft. deep, and were cut to lay $\frac{1}{4}$ -in. joints. In quarrying the dimension stone, plug and feathers were used to split the stone to size ready for cutting. The cost of quarrying and plug and feathering 4,000 cu. yds. of dimension stone ready for cutting was as follows:

	Days (10 hr.) per cu. yd.	Cost per cu. yd.
Foreman, at \$3.....	0.114	\$0.34
Drillers, at \$2.....	0.917	1.84
Laborers, at \$1.50.....	0.429	0.65
Blacksmiths, at \$2.50	0.102	0.25
Tool boys, at \$0.50.....	0.108	0.05
Labor loading teams, at \$1.50.....	0.284	0.42

Total (not including explosives and teaming) \$3.55

The work was done by contract in 1867-8. The rates of wages were not given by Mr. Croes, but Mr. John B. McDonald has been kind enough to give me most of the rates of wages as nearly as he can remember. The length of haul from quarry to stone yard was about a mile, and Mr. McDonald states that oxen were used. The cost of "teams" is given by Mr. Croes, as 0.62 team day per cu. yd., which indicates that a good deal of stone boat work was done, or else that there is an error in this item.

The cost of quarrying 3,400 cu. yds. of rubble stone for this same dam was as follows:

	Days per cu. yd.	Cost per cu. yd.
Foremen, at \$3.....	0.041	\$0.12
Drillers at \$2.....	0.339	0.68
Laborers, at \$1.50	0.149	0.21
Blacksmiths, at \$2.50	0.036	0.09
Tool boy, at \$0.50.....	0.035	0.02
Labor, loading teams, at \$1.50....	0.077	0.12
Teams, at \$4.....	0.141	0.56
Total labor		\$1.80

It is presumable that both the dimension stone and the rubble stone were measured in the dam.

The masonry was called "rubble range" a term that deceived most of the contractors, for the specifications in fact called for stones cut to lay in courses with $\frac{1}{4}$ -in. bed joints. During $3\frac{1}{2}$ years of work there were 5,200 cu. yds. of this "rubble range" cut, requiring the dressing of 6,373 sq. ft. Each stone averaged 1.8 ft. rise, 3.6 ft. long, and 2.7 ft. deep, or 0.65 cu. yd. per stone. Each stonecutter averaged 18.7 sq. ft. of bed joints dressed per day, so that it took 1.57 days to dress each cubic yard of "rubble range" stone.

The ashlar stones were called "dimension cut-stone masonry", and were cut to lay $\frac{1}{4}$ -in. joints both on bed and end joints, and the faces were pean hammered. The lowest bid on this ashlar was \$30 per cu. yd., but another contractor, who had previously done the same kind of work, bid \$60 per cu. yd.

It took 9 days' work of a stonecutter to dress each cubic yard of this ashlar.

The coping was laid in two courses; one course of stones 12-in. rise, 30-in. bed, and $3\frac{1}{2}$ -ft. length; the other course, 24-in. rise, 48-in. bed, and $3\frac{1}{2}$ -ft. length. The top was pean hammered, and the face was left rough with a chisel draft around it. The beds and joints were cut to lay $\frac{1}{4}$ -in. It took a stonecutter 6.1 days to dress each cubic yard of this ashlar.

The cost of laying the masonry in the dam was as follows, wages being assumed to be approximately what they are now (not what they were in 1876):

	Cost per cu. yd.			
	A	B	C	D
Mason, at \$3.00.....	\$0.36	\$0.36	\$0.25	\$0.32
Laborers, at \$1.50.....	0.28	0.28	0.22	0.22
Mortar mixers, at \$1.50.....	0.15	0.12	0.11	0.15
Derrick and carmen, at \$1.50.....	0.49	0.51	0.36	0.39
Engine, at \$4.00.....	0.18	0.20
Teams from yard, at \$3.50.....	0.35	0.20	0.20	0.22
Laborers loading teams, at \$1.50....	0.28	0.23	0.22	0.12
Total	\$1.91	\$1.80	\$1.65	\$1.81

Columns A and B relate to work done in 1868 and 1869 when the stone was hoisted by hand; A was a lift of 5 ft., B was a lift of 10 to 20 ft. Columns C and D relate to work done in 1869 and 1870, when the hoisting was done by engines; C being a lift of 20 to 30 ft.; D being a lift of 30 to 50 ft. It will be noted that each mason laid from $8\frac{1}{2}$ to $12\frac{1}{2}$ cu. yds. per day. Each engine apparently served two masons, but it is not stated whether each mason had a separate derrick or both worked with one derrick.

The stones were laid in inclined or sloping courses, which made it hard to keep them in place as a rap of a hammer would cause sliding.

It will be noted that the cost of loading and hauling the stone from the stone yard to the dam is included in the above costs of laying. This cost of loading and hauling is not properly a part of the cost of laying.

The mortar was a 1:2 mixture, natural cement, and it required

0.2 bbl. of cement, 0.093 cu. yd. sand, and 0.89 cu. yd. of stone per cu. yd. of dam masonry. In other words, only 11% of the masonry was mortar.

Cost of Plug Drilling by Hand.—By timing a number of masons at work splitting granite blocks 24 to 30 ins. thick, I found that each man drilled each hole ($\frac{1}{2}$ -in. diam. x $2\frac{1}{2}$ ins. deep) in a trifle less than 5 mins., by striking about 200 blows. It took about 1 min. for placing and striking each set of plug and feathers. A block 30 ins. long, with four plug holes, was drilled and split with the plugs and feathers in 24 mins., on an average. At this rate, a good workman can drill and plug 80 holes in 8 hrs., but it is not safe to count upon so large an average.

Cost of Pneumatic Plug Drilling.—For drilling plug holes in granite certainly no tool is as economic as the pneumatic plug drill. Horizontal as well as vertical holes can be rapidly drilled. The ordinary plug drill, according to the manufacturers, consumes 15 cu. ft. of free air per min. at 70 lbs. pressure. At the Wachusett Dam I found that a workman averaged one hole ($\frac{1}{2}$ -in. diam. x 3 ins.) drilled in $1\frac{1}{2}$ mins., including the time of shifting from hole to hole, but not including the time of driving the plugs. About 250 plug holes are counted a fair day's work for a plug drill where the driller does not drive the plugs himself.

Cost of Quarrying Granite.—Cost data relating to the quarrying of granite dimension stone are extremely hard to secure. I have been able to find only one writer, Mr. J. J. P. Croes, who has published anything on the subject. Mr. Croes' records, together with mine, will at least form a basis for approximate estimates of cost of granite quarrying. My data apply to quarrying three-dimension stone in a sheet quarry on the coast of Maine. The total number of men engaged was, on the average: 6 enginemen, 6 steam drillers, 6 drill helpers, 3 blacksmiths, 3 helpers, 5 tool and water boys, 38 quarrymen, 47 laborers, 2 foremen and 1 superintendent. This force quarried and loaded on boats about 1,400 cu. yds. of rough granite blocks. The stone was loaded by derricks onto cars from which it was unloaded into boats ready for shipment. The following cost includes everything except interest and depreciation of plant, and development expenses:

	Cost per cu yd.
Enginemen, at \$2 a day (of 9 hrs.).....	\$0.20
Steam drillers, at \$2.00.....	0.20
Drill helpers, at \$1.50.....	0.15
Blacksmiths, at \$2.75.....	0.14
Blacksmiths' helpers, at \$1.75.....	0.09
Tool and water boys, at \$1.....	0.16
Quarrymen, at \$1.75.....	1.09
Laborers, at \$1.50.....	1.15
Foremen, at \$3.00.....	0.15
Superintendent, at \$8.....	0.20
Coal, at \$5 ton.....	0.45
Explosives.....	0.25
Other supplies.....	0.20
Total	\$4.63

On the best month's work, when a larger force was being operated, the cost of all labor, superintendence and supplies, was reduced to a little below \$4 per cu. yd., but the above \$4.50 per cu. yd. may be taken as a fair average of several months' work. To this should be added the charges for plant rental, quarry rental (if any), stripping (if any), and freight charges to destination. The freight rate by boat from Maine to New York is about \$1 a ton, but as rough granite blocks are always measured on their least dimensions, the freight charges when \$1 per ton amount to about \$2.70 per cu. yd. of three-dimension stone in the rough. The explosives used were black powder, costing \$2.25 a keg (25 lbs.), and dynamite for channeling, costing 15 cts. a lb. The sheet from which this granite was quarried averaged about 6½ ft. thick, and was nearly flat. The stone was loosened in long blocks by Knox blasting with black powder, and was split up into sizes by plug and feathering; both hand drills and pneumatic plug drills being used for this purpose. The stone, as before stated, was three-dimension stone. To quarry random stone (not rubble) in this quarry cost about \$3.50 per cu. yd.

If granite is blasted out in all shapes and sizes, to be used for rubble or for concrete, the cost of quarrying is far less than the above and is approximately the same as quarrying trap rock, provided the two kinds of rock are equally seamy or jointed. Traps, however, are usually much more seamy than granites; hence the drill holes in trap can usually be spaced much farther apart than in granite having few seams.

Cost of a Masonry Arch Bridge.—This arch bridge had a span of 30 ft., and its barrel was 60 ft. long. The masonry was limestone laid in Portland cement mortar. There were 366 cu. yds. of masonry distributed as follows:

	Cu. yds.
Arch sheeting	112
Bench walls (or abutments)	165
Backing above arch	17
Backing above haunch	33
Wing walls	21
Parapet walls	7
Coping	5
Total	366

The arch sheeting masonry was dressed to lay ½-in. joints, and the cost of these 112 cu. yds. was as follows:

	Cu. yd.
Quarrying rough blocks	\$ 1.00
Plug and feathering into blocks	0.85
Hauling and loading onto car	0.75
Freight	1.05
Unloading from car and hauling 1 mile	0.70
Cutting	4.55
Laying	1.35
Mortar	1.50
Centers	2.20
Total	\$13.95

This sheeting was cut to lay an arch 18 ins. thick, each block averaging $12 \times 18 \times 28$ ins. in size, or about $\frac{1}{8}$ cu. yd. The blocks were small, but the quarry did not yield large material. Quarrymen were paid 30 cts. per hr. and helpers $17\frac{1}{2}$ cts. per hr. The unloading from cars onto wagons cost 35 cts. per cu. yd., wages being 15 cts. per hr.; and the hauling 1 mile cost 35 cts. per cu. yd., teams being 40 cts. per hr.

The stonemasons were paid 35 cts. per hr., and their work cost \$4.35 per cu. yd.; the sharpening of cutters' tools cost 15 cts. more per cu. yd.; and the help of laborers occasionally in bunkering a stone cost another 15 cts. per cu. yd.; making a total of \$4.55 for cutting the stone after it had been plug and feathered roughly into blocks. The small size of the blocks made this cost high.

The stone was laid by a hand-power derrick, the cost of laying being in detail as follows:

	Per cu. yd.
Masons, at 30 cts. per hr.....	\$0.80
Helpers, at 15 cts. per hr.....	0.45
Team on stone boat, 40 cts. per hr.....	0.10
Total cost of laying.....	\$1.35

Each mason had $1\frac{1}{2}$ helpers and laid 3 cu. yds. in 8 hrs. This was the average of all the 365 cu. yds. of masonry; the cost of laying each kind was not kept separately.

The mortar was 1:3 Portland cement, allowing 4.5 cu. ft. per bbl.; it took 2 bbls. of cement and 0.9 cu. yd. sand to make 1 cu. yd. mortar; and the cost of these materials was \$4.50 per cu. yd. of mortar. It took $\frac{1}{2}$ cu. yd. of mortar for each of the 365 cu. yds. of masonry; no attempt was made to determine the amount of mortar for each kind of masonry.

The cost of the ashlar facing in the abutments and wing walls was the same per cubic yard as the arch sheeting after deducting the \$2.20 for centers, that is \$11.75 per cu. yd.; and there were about 60 cu. yds. of this in the bridge.

The cost of the rubble backing in the abutments, haunch, etc., of which there were nearly 200 cu. yds., was as follows:

	Per cu. yd.
Rubble sandstone delivered at bridge.....	\$1.20
$\frac{1}{2}$ cu. yd. mortar, at \$4.50.....	1.50
Laying	1.35
Total	\$4.05

This rubble was a local sandstone, but the ashlar was a limestone imported by rail.

The foregoing costs do not include foreman's salary and general expenses, which amounted to 15% of the total cost of the bridge. In addition to the 365 cu. yds. of stone masonry there were 65 cu. yds. of concrete foundations laid on a hard clay. There was no coffer-damming.

The cost of the work was higher than it would have been under a better foreman.

Cost of Centers for 30-ft. Arch.—Centers for a masonry arch of

30-ft. span and having a barrel 60 ft. long were made of hemlock. There were 21 arch ribs or centers spaced 3 ft. apart and lagged with hemlock 2 ins. thick by 6 ins. wide. Each center was made of two thicknesses of 2 x 12-in. plank cut in section 6 ft. long and spiked together, breaking joints. The ribs were cut to the curve of the arch at a saw mill. The following was the bill of timber in each center:

	Ft. B. M.
6—2-in. x 12-in. x 12-ft. curved ribs.....	144
4—2-in. x 6-in. x 16-ft. ties	64
1—2-in. x 6-in. x 10-ft. splices	10
1—2-in. x 6-in. x 10-ft. post	10
2—2-in. x 6-in. x 16-ft. struts	32
Total per bent.....	260
22 centers at 260 ft. B. M.....	5,720
Lagging 2 ins. x 33 ft. x 60 ft.....	3,960
Total	9,680

The machine work at the mill cost \$20, and the carpenter work of framing the centers was \$7.75 for carpenters at 22½ cts. per hr. and \$9.25 for carpenters' helpers at 15 cts. per hr., making a total of \$37. This is equivalent to \$6.50 per M when distributed over the 5,720 ft. B. M. in the centers. The cost of erecting the centers with the aid of a hand-power derrick together with the cost of placing the lagging was \$24, all this work being done by laborers at 15 cts. per hr. This \$24 distributed over all the 9,712 ft. B. M. is \$2.56 per M. The cost of removing the centers after completion of the work was \$10, wages being 15 cts. per hr., or \$1.05 per M. The total cost of the centers was:

9,712 ft. B. M. hemlock, at \$16.....	\$155.51
132 oak wedges, at 10 cts.....	13.20
230 lbs. wire nails, at 3½ cts.....	8.05
Machine work at mill.....	20.00
Work framing centers	17.00
Work erecting centers	24.00
Work tearing down centers.....	10.00
Total	\$247.76

It will be noted that the millwork and labor cost \$71, which is equivalent to \$7.30 per M distributed over the 9,712 ft. B. M. There were 112 cu. yds. of masonry in the arch alone, so that the cost of the centers distributed over the arch sheeting was \$2.20 per cu. yd. But there were 250 cu. yds. of masonry, all told, in the arch, the abutments, parapet and wing walls. The short posts supporting the centers rested on hard clay.

Cost of Arch Culverts and Abutments, Erie Canal.—In 1840 contracts were let for enlarging the Erie Canal. The courts later declared the law making the appropriation unconstitutional and the New York State Legislature directed that the contracts be canceled and that contractors be paid their prospective profits. The 12 engineers in charge of the work submitted the following estimates of the actual cost. The stone in masonry was limestone from the lower Mohawk valley. Masons and stonecutters were paid \$2.25 per day

of 11 hrs. worked, laborers \$1. The cost of masonry in arch culverts and bridges was as follows:

Face stone:	Per cu. yd.
Quarrying, 1 cu. yd. per man day.....	\$2.25
Cutting, 1.8 cu. yds. per man day.....	2.25
Laying, 0.7 cu. yd. per man day.....	1.25
Mortar	0.75
Total, not including hauling.....	\$4.50

Note: The cost of quarrying includes sharpening drills, foremen, etc.

Backing (rubble):	
Quarrying, 2 cu. yds. per man day.....	\$1.00
Laying, 1.75 cu. yds. per man day.....	1.00
Mortar	1.25
Total, not including hauling.....	\$3.25

Arch sheeting:	
Quarrying, 1 cu. yd. per man day.....	\$2.25
Cutting, 0.88 cu. yd. per man day.....	3.25
Laying, 0.7 cu. yd. per man day.....	1.25
Mortar	1.00
Total, not including hauling, or centers.....	\$7.75

Ring and Coping:	
Quarrying, 0.8 cu. yd. per man day.....	\$ 3.40
Cutting, 0.55 cu. yd. per man day.....	5.00
Laying, 0.58 cu. yd. per man day.....	3.00
Mortar	0.50
Total, not including hauling.....	\$11.90

The cost of hauling stone 1 mile from quarry to canal was 50 cts. per cu. yd., 7 round trips being made per day by a team hauling $\frac{1}{2}$ cu. yd. of stone, as measured in the work.

The centers for arch culverts of 4 to 8-ft. span were estimated to cost 50 cts. per cu. yd. of arch masonry. For spans of 10 to 15 ft. the centers cost 75 cts. per cu. yd. of arch masonry.

Timber stringers covered with 2 or 3-in. plank were largely used for foundations and floors of culverts. The cost of placing such timber was \$4 per M.

Cost of Lock Masonry, Erie Canal.—The following is a continuation of the data just given:

The masonry for locks was dressed as follows: Cut stone face, $\frac{1}{2}$ -in. joints; hammer dressed backing, 1-in. joints. Wages were as above given.

Lock face stone:	
Quarrying, 0.67 cu. yd. per man day.....	\$ 3.00
Cutting, 0.50 cu. yd. per man day.....	5.50
Laying, 3.00 cu. yds. per man day.....	0.83
Mortar	0.50
Machinery	0.25
Total, not including hauling.....	\$10.08

Lock backing (1-in. joints):	
Quarrying, 1 cu. yd. per man day.....	\$2.00
Cutting, 1.8 cu. yds. per man day.....	1.50
Laying, 4 cu. yds. per man day.....	0.92
Mortar	0.75
Machinery	0.25

Total, not including hauling..... \$5.12

The average cost of lock masonry, including face and backing, was \$1.70 per cu. yd., exclusive of transportation which was \$2.75 per cu. yd.

The cost of a masonry aqueduct consisting of masonry piers, arches and spandrels, was as follows:

To lay masonry:		Per day.
1 mason		\$2.25
2 tenders, at \$1.....		2.00
1/2 stone cutter, at \$2.40.....		1.20

Total, 5.9 cu. yds. laid, at \$0.92 per cu. yd...\$5.45

To lay arch masonry:		Per day.
1 mason		\$ 2.25
2 tenders		2.00
1 stone cutter		2.50

Total, 8.95 cu. yds. laid at \$0.76 per cu. yd...\$ 6.75

To lay spandrel masonry:		Per day.
1 mason		\$ 2.25
2 tenders		2.00
1 1/2 stone cutters		4.00

Total, 8.25 cu. yds. laid at \$1 per cu. yd....\$ 8.25

The total cost of aqueduct masonry, per cubic yard, excluding the cost of laying just given, was as follows:

	Per cu. yd.
Quarrying	\$ 2.25
Transportation	2.00
Cutting	2.25
Mortar	1.00
Machinery	0.25

Total, not including laying.....\$ 7.75

Approximately \$0.90 per cu. yd. should be added to this \$7.75 to include cost of laying the masonry.

Cost of Sweetwater Dam.—James D. Schuyler gives the following data on the Sweetwater Dam, California: The dam is 46 ft. thick at the base, 12 ft. at the top, and 90 ft. high. It is built as an arch with a radius of 222 ft. on line of face at the top. The stone was a metamorphic (or igneous?) rock with no well-defined cleavage, breaking out in irregular masses. Its weight ranged from 175 to 200 lbs. per cu. ft. And the average weight of the masonry was estimated to be 164 lbs. per cu. ft. The mortar was a 1 : 3, proportioned by barrels, mixed in a Ransome mixer. The mixer was given 2 or 4 turns after charging it with sand and cement, then the water was admitted during the next 3 or 4 revolutions; 8 to 10 revolutions made a thorough mixture, requiring 2 to 3 mins. A tramway for delivering the mortar was carried around the face of the dam, on a bracket trestle held by bolts driven into

holes drilled in the face of the dam masonry. A grade of 3 ft. in 40 at the end of the tramway next to the mixer was sufficient to give the mortar car an impetus that would carry it to the farthest end of the dam. By using this mechanical mixer and tramway a force of 5 men and a horse did the work formerly done by 4 mortar mixers and 14 hod carriers. The box of mortar was lifted from the car by a derrick and delivered to the masons.

The stone was quarried from a cliff 100 ft. high situated 800 ft. below the dam. It was hauled in wagons rigged with platforms on a level with the rear wheels. The quarry derricks were simple shear-legs, slightly inclined. All stones smaller than 500 lbs. were loaded on stone boats 4 ft. square, made of 3-in. plank with a bottom of boiler plate and provided with chains at the corners. The shear-leg derricks were used to hoist the stone boats and deposit their loads on the wagons. Stone boats cost \$30 each, and several sets of them were worn out on the job. A single stone, weighing 3 tons or more, was readily lifted by the shear-legs, and lowered upon a wagon driven underneath. All hoisting was done by horse power. Four derricks were used on the dam, masts being 30 to 38 ft. long, and booms 25 to 32 ft. A fifth derrick, with a 50-ft. mast and a 45-ft. boom, proved far more efficient than the others. The work was completed Apr. 7, 1888, after 16 mos.

The masonry was rubble throughout, amounting to 20,507 cu. yds., of which 19,259 cu. yds. were in the dam proper; 0.86 bbl. of cement was used per cubic yard of masonry.

The cost of the dam was as follows:

17,582 bbls. cement	\$ 62,111
Hauling cement	8,614
Lumber	2,408
Iron work	4,916
Powder and miscellaneous supplies.....	3,220
Pipes, gates, etc.....	5,152
Plant, tools, etc.....	6,237
Total for materials and plant.....	\$ 93,668
Labor, common and skilled.....	\$ 93,591
Foremen	6,866
Teams	19,896
Engineering	10,555
Clerical work	654
Earthwork (by contract).....	7,666
Miscellaneous expenses	1,377
Total for labor	\$140,405
Total for materials, etc.....	93,668
Grand total	\$234,073

Common laborers were paid \$2 to \$2.50 a day; masons, \$4 to \$5; carpenters, \$3.50 to \$4; blacksmiths, \$4; teams with drivers, \$5; machinists, \$7 to \$8; foremen, 4 to \$6. Workmen were scarce and independent on account of the "boom" in California. The work cost 20 to 25% more than it would have cost under normal conditions.

The itemized cost of 11,322 cu. yds. of the masonry laid from May 1 to Dec. 31, 1887, was as follows per cubic yard:

	Per cu. yd.	Percentage of total.
Quarrying stone (labor).....	\$ 0.425	4.829
Loading stone	0.523	5.982
Hauling stone	0.420	4.758
Hoisting stone	0.577	6.550
Loading and hauling sand.....	0.345	3.915
Cement, at \$4.20 per bbl.....	3.427	38.900
Mixing and delivering mortar.....	0.289	2.710
Masons	0.797	9.050
Helpers	0.186	2.109
Excavating foundations	0.303	3.444
Making and repairing roads.....	0.118	1.336
Blacksmithing (labor)	0.153	1.854
Carpentry	0.097	1.104
Rope	0.104	1.184
Tools	0.046	.524
Steel	0.014	.155
Blacksmith coal.....	0.009	.109
Blocks and sheaves.....	0.011	.131
Powder	0.086	.974
Lumber	0.195	2.220
Wetting masonry	0.048	.542
Foremen	0.323	3.774
Engineering and superintendence...	0.343	3.891
Total	\$ 8.808	100.000

Cost of a Granite Dam, Cheyenne, Wyo.—Mr. A. J. Wiley gives the following data on a dam for the Granite Springs Reservoir, Cheyenne. The work was done by contract, April 20, 1903, to June 21, 1904. From Nov. 20, 1903, to April 11, 1904, work was closed down on account of cold weather. The extreme height of the dam is 95 ft., and the length of the crest is 410 ft.; the thickness at the base is 56 ft., and on the top it is 10 ft. It contains 14,222 cu. yds. of granite rubble masonry laid in 1:4 Portland mortar, except for the face of stones where 1:3 mortar was used. The mortar constituted 35.2% of the dam; and 0.61 bbl. cement was used per cubic yard of masonry.

The mortar was mixed with a Smith mixer, in batches of $\frac{1}{2}$ cu. yd., and the mixer output was 6 cu. yds. per hr. The mortar was dumped into buckets and carried on cars running on a trestle built along the up-stream face of the dam. Derricks on top of the dam hoisted the mortar buckets.

The stone was a gabbro, quarried about 100 ft. below the dam. It was devoid of cleavage and was blasted out in large masses from an open face 20 to 40 ft. high. The drilling was done by hand. For each cubic yard of rock there were used 0.35 lb. of dynamite and 1.05 lbs. of black powder. The stones averaged 2 cu. yds., but pieces containing 5 cu. yds. were used.

Rocks breaking smaller than 3 cu. yds. were used as they were blasted out of the quarry, and larger masses were split up by plug and feather into roughly rectangular shapes. The best shaped stones were used for face stones, the ordinary rough rocks were used in the body of the dam, and the smaller pieces made the spalls. The rock was taken from the quarry by a guyed derrick with 40-ft. boom, and loaded upon platform cars. The track was laid upon such a grade that the loaded cars ran alone and the empties were

pushed back by hand. The trestle which carried the track was supported by the steps on the down-stream side of the dam. Upon the top of the dam were located two guyed derricks with 40-ft. booms similar to the quarry derrick. Each of the three derricks was operated by a 10-ton hoisting engine located in an engine house near the south end of the dam. The derricks on top of the dam took the rock from the cars on the lower side of the dam and set them in the masonry. They also took the mortar buckets from the cars on the up-stream side of the dam and dumped them where needed on top of the dam.

Spalls were brought upon the dam in skips, holding about a cubic yard each, and kept in the skips until used. The mortar was usually dumped in half-yard batches in a convenient depression of the masonry, and was distributed with long-handled, round-pointed shovels.

The up-stream face was laid with the joints in the true plane of the face. No objection was made to having the convexity of a stone project beyond this plane, but no stones with concave faces were permitted in the face of the dam. The upper 20 ft. of the down-stream face were laid in the same manner, but the rest of the down-stream face was laid in rough steps with half the step inside and half outside the theoretical plane of this face. The stones in both these faces were laid to break joint and were well bonded into the body of the dam. In the body of the dam but little attention was paid to the bond of the work, the irregular stones insuring this without effort, but every precaution was taken to insure the filling of voids. To this end the mortar was used very wet, even sloppy, and the chief rule observed was that there should first be placed a large excess of mortar of which the largest possible percentage was to be displaced by rock. In setting the large rock, a bed was prepared with spalls and mortar, and then a considerable excess of mortar was placed on the bed. The rock was then slowly lowered and settled on the bed by working it with bars. The excess mortar would come from under the rock which would then float upon an even layer of mortar, filling all the spaces under it. During this operation the inspector, either standing upon the rock or having his hand upon it, can tell if the rock is riding or rocking, and, if necessary, has the rock raised and the bed readjusted. The large rocks were set as close as possible to each other without being in contact, the intervening spaces being filled with mortar and spalls. In this work the masons were not permitted to sandwich the spalls between layers of mortar, but were required first to fill the space with wet mortar in which the spalls were submerged, displacing as much as possible of the mortar. While it was the intention to have the masonry brought up in horizontal benches extending the full length of the dam, the exigencies of the work prevented this and the middle portion of the dam was completed first, stepping off toward each end. The average rate of progress was 60 cu. yds. of masonry per day of ten hours. The best monthly rate was 2,370 cu. yds. during July.

1902, averaging 83 cu. yds. for a ten-hour day, or 41.5 yds. of masonry per ten-hour day for a single derrick, including the time lost in moving and resetting derricks. During this month the average daily force employed was as follows: In the quarry, 21.3 men, 1½ engine runners, and one derrick; in screening and hauling sand, 3.2 teams with drivers, and 3.2 men; in mixing and delivering mortar, 3 men; in laying masonry, 3.5 masons, 6.5 helpers, 2½ engine runners, and 2 derricks.

The following were the average wages paid per 10-hr. day: Quarrymen, \$2.50; masons, \$5.00; masons' helpers, \$2.25 to \$2.50; engine runners, \$3.00; common labor, \$2.25.

The actual cost of the masonry was as follows:

	Per cu. yd.
0.652 cu. yd. solid rock, \$1.96.....	\$ 1.28
0.348 cu. yd. mortar (not incl. cement), at \$1.93.	0.67
0.613 bbl. cement, at \$3.58, delivered.....	2.19
Labor laying 1 cu. yd.....	1.11
Total	\$ 5.25

The solid rock was quarried and delivered for \$1.96 per cu. yd. (solid), itemized as follows:

	Per cu. yd. (solid).
Quarrying and Delivering:	
Common labor	\$ 1.06
Engine runners	0.14
Coal, \$6 per ton.....	0.08
Blacksmithing	0.13
Steel	0.04
Explosives	0.15
Interest and dep. on plant (\$1,644).....	0.18
General expenses	0.18
Total per cu. yd. (solid).....	\$ 1.96

This is equivalent to \$1.28 per cu. yd. measured in the dam.

The cost of securing the sand and mixing the mortar was as follows per cu. yd. of mortar:

	Per cu. yd.
Labor digging and hauling (teams) sand.....	\$ 1.10
Blacksmithing, sand pit	0.13
General expense, sand pit.....	0.19
Labor mixing and delivering.....	0.30
Fuel, \$6 per ton.....	0.04
Interest and depreciation on plant (\$620).....	0.12
General expense	0.05
Total per cu. yd. mortar.....	\$ 1.93

The cost of laying the masonry was as follows per cu. yd. of masonry:

	Per cu. yd.
Labor, masons and helpers.....	\$ 0.50
Engine runners	0.18
Fuel, \$6 per ton.....	0.10
Blacksmithing	0.02
Interest and depreciation on plant (\$3,000).....	0.22
General expense	0.09
Total	\$ 1.11

The interest and depreciation on the plant was assumed to be

50% of the first cost of the plant. The fuel was estimated on the basis of 5 lbs. of coal per horse-power hour of actual working time for the nominal horse-power of the engines. As a matter of fact, a large amount of cord wood was used instead of coal.

Cost of Masonry, New Croton Dam.—This dam was built of gneiss (a granitic rock), and the average cost to the contractor during the years 1897 to 1905 was about as follows for the rubble masonry:

	Per cu. yd.
0.95 bbl. cement, at \$1.85.....	\$1.75
Quarrying $\frac{1}{2}$ cu. yd. solid stone, at \$1.50.....	1.00
Sand, $\frac{1}{4}$ cu. yd., at \$0.90.....	0.30
Labor laying masonry.....	0.90
Pumping	0.10
Plant, roads, etc.....	0.60
General expense, 2% estimated.....	0.10
Total	\$4.75

In quarrying about 25% of the rock was wasted.

In laying the masonry cableways were used for about half the yardage, and steel towers with derricks were used for the other half.

Some of the face stone was dressed. The rough pointing of 38,000 sq. ft. cost \$0.60 per sq. ft. The 6-cut ax work on 84,000 sq. ft. cost \$1.20 per sq. ft.

Cost of a Rubble Dam.—This dam was built in 1898 by contract, under the direction of Mr. George W. Rafter, across the Indian River, Hamilton County, N. Y. The main dam was 7 ft. wide on top, 47 ft. high, 33 ft. wide on bottom, and 400 ft. long. The face masonry was dressed to lay $1\frac{1}{2}$ -in. joints. The backing was large irregular rubble stones laid in beds of 1 : $3\frac{1}{4}$ mortar, and the vertical joints filled with 1 : $3\frac{1}{4}$: $7\frac{1}{2}$ concrete. No attempt was made to keep separate accounts of the face masonry and the backing, but it was estimated that 27% of the dam was mortar. The stone was a pink syenitic granite, quarried 500 ft. from one end of the dam. There was no difficulty in quarrying regular blocks for the face. The sand was loaded upon a scow holding 30 cu. yds. and hauled 2 miles down the river. A foreman and 6 men, by using a windlass, rope and sail, handled the scow. They loaded and delivered 720 cu. yds. of sand and 180 cords of wood per month, at a cost of about \$310. Wages of common laborers were \$1 a day and board, and it is probable that the board cost \$0.50 per man per day.

The plant to build the dam cost \$10,840. The actual cost of the dam to the contractor was:

Labor clearing 35 miles of margins, 1,160 acres.....	\$13,000
Hauling cement and supplies 22 miles.....	6,886
Freight, cement and supplies.....	960
Barn account (teams owned by contractor)....	725
Stone, cement and other materials.....	18,830
Labor (not including clearing).....	81,218
General expense	9,601

Interest	1,150
Insurance	1,235
Depreciation of plant, est. 33%.....	3,450
Total	\$87,005

The "general expense" includes coffer-damming and pumping, erecting and wrecking the plant, etc. The time occupied in doing the work was 7 months.

In July and August, when the work was well under way, the cost of the masonry was very low, and averaged as follows:

	Per cu. yd.
Quarrying face stone (not incl. backing).....	\$0.35
Labor laying masonry	0.53
Labor pointing masonry	0.15
Mixing mortar and concrete, and crushing.....	0.20
Cement	2.00
Sand	0.15
General expense and superintendence.....	0.27
Total	\$3.65

In addition to this there was the cost of quarrying the stone for the backing; but this stone was paid for as excavation, so it is not included above. During July and August this excavation cost 46 cts. per cu. yd.

It will be noted that the accounts were not well kept, for no statement is given of the proportion of backing to face stone. The quarrying of the face stone doubtless cost several dollars per cubic yard of the face stone, although it amounted to only \$0.35 per cu. yd. when distributed over all the masonry. Nor is it stated what the dressing cost. From measurements on a drawing of the cross-section of the main dam, I estimate that it runs 29 cu. yds. of masonry per lin. ft., of which about 30% is face stone, if we allow a depth of 2½ ft. of face stone extending into the dam; but in the lower third of the dam, where there is great breadth, the face stone would not be more than 20% of the total masonry, and at the bottom only 15%. Hence if the work in July and August was in the lower part of the dam, as it doubtless was, we must multiply the \$0.35, above given, by at least 5 to secure an approximate estimate of the cost of quarrying a cubic yard of face stone. Indeed, it is likely that the cost of face stone was more than 5 times \$0.35 per cu. yd.

I have gone into these details for the purpose of showing how little value there often is in published cost records, because of the failure of engineers to keep their cost records properly. The wages of quarrymen and masons are not given.

Data on Laying Masonry With a Cableway.—Mr. Spencer Miller gives the following data on the use of cableways for laying masonry. The Basin Creek Dam for the water-works of Butte, Mont., is 120 ft. high and 300 ft. long, designed by Mr. Chester B. Davis. A cableway 892 ft. between towers, spanned the dam and the quarry. No derricks were used on the dam, for, by using a snubbing post and a horse, the stones could be swung where desired.

In 16 days a gang of 86 men quarried and laid 1,436 cu. yds. of masonry. This gang included 6 masons, quarrymen, firemen and all laborers about the dam and camp. These six masons averaged 15 cu. yds. of masonry each per day.

At Rochester, N. Y., two cableways, side by side and 40 ft. apart, were used to erect a stone arch bridge 630 ft. long and towers 50 ft. high. A 30-hp., $8\frac{1}{4} \times 10$ -in. engine was used for each cableway. Stones were laid between the cableways by hitching the hoisting lines of both cableways to the same stone. To lay the masonry piers a frame was used which straddled the piers and on top of which a traveler was used to place the stone as fast as it was delivered by the cableway. After a pier was completed the framework and traveler were lifted by the cableways to the site of the next pier, in less than 10 minutes. The centers for the arches were lifted into place by the cableways. This highway bridge contained 2,200 cu. yds. of masonry in piers and arches, 2,278 cu. yds. arch sheeting, 2,560 cu. yds. concrete spandrel backing, and 310,000 lbs. of iron work; 350 M of lumber were used in the centers.

Cost of Masonry and Timber Crib Dam.—Mr. Maurice S. Parker gives data on the Black Eagle Falls Dam, Missouri River, Great Falls, Mont. The work was done by day labor (Apr. 15, 1890, to Jan. 6, 1891) under Mr. Parker's supervision, wages being as follows: Common labor, \$2; stone masons, \$4; carpenters, \$3.50; quarrymen, \$2.25; stone cutters, \$4.50; quarry foremen, \$3.50; mason foremen, \$5; stone cutter foremen, \$5; carpenter foremen, \$5.

The stone was a red sandstone weighing 160 to 170 lbs. (some specimens 178 lbs.) per cu. ft., and was quarried from the bed of the river, the average haul being 500 ft. on push cars. The stone occurs in vertical strata 1 to 4 ft. thick, the bedding planes making an angle of 45° with the current. Timber was delivered near the gate chambers. Cement used was Milwaukee and Buffalo mixed 1:2. Portland cement was used in freezing weather and gave perfect satisfaction, being now as hard as stone. The following table gives the cost of the labor in construction, including all handling of materials after unloading from cars:

	Cost of labor.
4,600 cu. yds. first class rubble, at \$6.56.....	\$30,436
1,500 cu. yds. cut stone masonry, at \$16.40.....	24,600
5,000 cu. yds. dry stone filling in cribs, at \$2.10.....	10,500
10,000 cu. yds. excav., half rock, half earth, at \$1.07.....	10,700
1,200 M timber in cribs, at \$10.85	13,020
100 M timber in gates and chambers, at \$33.72.....	3,372
Engineering expenses, 12 mos.....	5,900
Total cost of labor.....	\$98,530

The expense of false work of all kinds, such as cofferdams, tramways, etc., amounted to 6% of the total cost and is divided proportionately between the classes of work above given. The cost of labor on timber in gates and chambers includes the cost of placing all irons and gearing. The total cost of the dam was \$175,000.

including materials, labor and salaries. About 30% of the rubble was broken range faced. The cut-stone masonry was laid with close beds and joints.

The minimum flow of the river is 4,000 cu. ft. per sec. The average depth of water was 3 ft. when work was begun, but it was very swift as the rapids at the site of the dam had a fall of 2 ft. in a 100 ft. During June floods the depth was 6 ft. The crib dam is 745 ft. long, and the canal and gates occupy an additional width of 26 ft. The average height of the dam is 14 ft., resting on a ledge of sandstone. The longitudinal timbers of the crib are spaced 3 ft. c. to. c. The bottom timbers were cut to fit the rock, bedded in cement mortar and drift bolted to plugs of wood driven into holes drilled in the ledge rock.

The work was begun on the north side of the river, a sheer dam being first built to divert the stream from the dam site. This sheer dam consisted of wooden horses placed 3 ft. apart, with stringers of 4-in. plank. A facing of 2-in. tongue and grooved planks was placed on the up-stream legs of the horses, and a row of sand-filled bags placed at the toe of the planks. There was a little leakage, and the leakage water was diverted by a second row of sand bags parallel with the first row, and a short distance down stream. This sheer dam withstood a flood 6 ft. deep.

On the south side of the river, which was deeper and swifter, it was necessary to sink small triangular stone-filled cribs to support the wooden horses for the sheer dam. These cribs were of 4-in. plank with 4-in. posts, each holding 1 cu. yd. of stone, and were placed 3 ft. apart, each crib supporting a horse. At times the depth of water against this sheer dam was 15 ft., but the leakage was easily cleared with hand pumps.

To close the long gap between the two ends of the dam, wooden horses were placed 3 ft. apart with a foot walk of 4-in. plank on top, and heavy timbers to hold the horses down. From this temporary bridge a second tier of horse bents was placed (3 ft. c. to c.) on the up-stream side, connected with 4-in. stringers and sheathed with 4-in. plank. The dam was intended to break the force of the current, which it did admirably. The leakage was taken care of in sections by small sheer dams built of matched plank, and by the use of sand bags. Every 48 ft., an opening of 14 ft. was left in the crib dam which was used as a temporary sluiceway when the cofferdam was removed. These gaps were subsequently closed with planks, and the cribwork with its stone filling built in.

Cost of Laying Masonry, Dunning's Dam.—Mr. E. Sherman Gould is authority for the following data on The Dunning's Dam near Scranton, Pa. The dam is masonry on a concrete foundation, built by contract. The stone for the masonry was a conglomerate laid in swimming beds of mortar. On one occasion one foreman, 3 masons and about 9 helpers laid nearly 500 cu. yds. of rubble in 76 hrs., using a double drum engine and derrick. This is equivalent to 2.3 cu. yds. per 10-hr. day per mason. On another occasion, another foreman, 7 masons and 8 or 9 helpers laid 375 cu. yds.

in 7 days, or 7.6 cu. yds. per mason per day. This was very rapid work in both cases.

Cost of Quarrying and Laying a Limestone Wall.—Mr. James W. Beardley is authority for the following data on the cost of quarrying and laying limestone for retaining walls on the Chicago Canal. The contractors selected parts of the canal where the limestone occurred in strata and were uniform, so that the beds of the stone quarried required no dressing. The stone was laid in courses averaging about 15 ins. thick, the better stone being selected for the face of the wall. Guy derricks having a capacity of 6 to 10 tons, boom 40 to 60 ft. long, operated by a hoisting engine, were used for loading the stone. Black powder was used to shake up the ledges and the stone was then barred and wedged out. The cost per cu. yd. is the average of 93,500 cu. yds., measured in retaining walls. The mortar was only 13¼% of the wall, indicating an unusually even bedded stone that squared up well. The cost does not include general superintendence, installation of plant, plant rental, powder, material for repairs, and cost arising from delays.

Mr. Beardley has evidently divided the number of working days credited to each class of men by the total number of days worked on the job, which results in giving fractions of days labor in the following typical force:

	Per cu. yd. masonry.
Quarry force:	
1 foreman, at \$3.50.....	\$0.078
2.11 derrickmen, at \$1.50	0.075
8.42 quarrymen, at \$1.65	0.312
1.10 enginemen, at \$2.25	0.052
2.28 laborers, at \$1.50	0.080
0.33 waterboy, at \$1.00	0.007
0.27 blacksmith, at \$2.50	0.013
0.18 blacksmith's help, at \$1.75	0.007
0.36 drill runner, at \$2.00	0.022
0.07 drill helper, at \$1.50.....	0.002
0.04 watchman, at \$1.50	0.001
0.29 team, at \$3.50	0.028
1.12 derricks, at \$1.25	0.040
0.36 drill, at \$1.25	0.015
Total quarry force	\$0.723
Wall force:	
1 foreman, at \$4.25	\$0.112
4.20 masons, at \$3.50	0.264
1.46 masons' helpers, at \$1.50.....	0.058
1.81 mortar mixers, at \$1.50.....	0.073
0.66 mortar laborer, at \$1.50	0.027
1.32 hod carriers, at \$1.50.....	0.073
1.77 derrickmen, at \$1.50	0.071
1 engineman, at \$2.25	0.054
1.62 laborers, at \$1.50	0.065
0.45 waterboy, at \$1.00	0.009
0.86 team, at \$3.50	0.078
0.20 carpenters, etc., at \$2.50.....	0.010
1.59 derricks, at \$1.50	0.042
Total wall force	\$1.027

This wall force of 16 men laid 27 cu. yds. per 10-hr. day, each mason averaging 3.8 cu. yds. The rates for derricks, etc., apply to the cost of fuel, at \$2 a ton. The wall derricks were stiff-legs, having booms 40 ft. long, and were moved on a track parallel with the wall.

Work was done between Sept., 1894, and Oct., 1896, with a plant having a total value of \$30,200. The total cost of the masonry was as follows:

Quarry force	\$0.73
Wall force	1.03
Sand, at \$1.85 per cu. yd.	0.13
Cement, at 60 cts. per bbl.	0.24
Total	\$2.13

Cost of a Masonry Wall, Including Excavation.*—The work was done in September, 1896, and consisted of the construction of a retaining wall at the round house of the Detroit, Lansing and Northern R. R., at Grand Rapids, Mich. The contractor furnished the labor only, the material being furnished by the railroad com-

Fig. 1. Masonry Abutment.

pany. The wall was built in the shape shown in Fig. 1, as it was desired to utilize it as the foundation for a future extension of the round house.

Excavation.—The excavation was nearly all stiff clay with stone and small boulders, thus making hard digging. Almost all of the excavated matter was handled twice, cast out on the ground and then loaded on flat cars. The time given for excavation includes, perhaps, six or eight dollars' worth of time spent in moving cars. In all of the work the contractor was considered as a foreman and was allowed 40 cents per hour for the time he himself actually worked. In all of the cases the foremen hours are for the hours during which actual work was done by them. That is to say, the foreman not only acted as overseer, but also did actual work, excavating, laying stone, etc.

The cost of the excavation work was as follows:

Foreman, 33 hours, at 40 cts. per hour	\$13.20
Foreman, 104 hours, at 22½ cts. per hour	23.40
Laborer, 285 hours, at 12½ cts. per hour	35.63
Total	\$72.23

**Engineering-Contracting*, May 20, 1906.

A total of 168.1 cubic yards was excavated at a cost of \$0.43 per yard. The contract price at which the work was let was \$0.25.

Back Filling.—In back filling the earth was wheeled from the flat cars and placed back of the wall. A small amount of earth was cast in directly from the bank. The cost of this work was as follows:

Foreman, 4 hours, at 40 cts. per hour.....	\$1.60
Foreman, 11 hours, at 22½ cts. per hour.....	2.48
Laborer, 52 hours, at 12½ cts. per hour.....	6.50
Total	\$10.58

The back filling amounted to 68 4/10 cu. yds., and this was done at a cost of \$0.17 per cubic yard. The contract price was \$0.25 per cubic yard.

Concrete.—The proportions for the concrete were 1:2½:5, Akron (natural) cement being used. All conditions were favorable for fair work. It was found that 1 cu. yd. of concrete was equivalent to 29.8 cu. ft. of material, composed of 3.6 cu. ft. cement (1 1/10 bbl.), 8.4 cu. ft. sand (2 7/10 bbl.) and 17.8 cu. ft. broken stone (6½ bbl.).

The cost of 15½ cu. yds. of concrete was as follows:

Foreman, 14 hours, at 40 cts. per hour.....	\$ 5.60
Foreman, 20 hours, at 22½ cts. per hour.....	4.50
Laborer, 49 hours, at 12½ cts. per hour.....	6.11
Mason, 2 hours, at 35 cts. per hour.....	.70
Total	\$16.91

A total of 15½ cu. yds. concrete was prepared at a cost of \$1.09 per cubic yard; the contract price was \$1.00 per cubic yard.

Stone Laying.—In the stone laying, Petoskey limestone was used. The limestone weighed, according to car weights, 5.3 tons per cord, equal to 93 lbs. per cubic foot of piled stone. Conditions were fair for good work. It was here found that 1 cu. yd. rubble masonry required 0.25 cord stone, 0.22 cu. yds. sand and 0.54 bbl. cement.

Akron (natural) cement, one barrel containing 3½ cu. ft., was used and the mortar was mixed in the proportions of 1:3. In the force account given below the foreman laid stone, and all other foreman hours are for actual work.

The cost of laying the 82.2 cu. yds. of rubble is shown in the following table:

Foreman, 78 hours, at 40 cts. per hour.....	\$31.20
Foreman, 80 hours, at 22½ cts. per hour.....	18.11
Mason, 41 hours, at 35 cts. per hour.....	14.52
Laborer, 168 hours, at 12½ cts. per hour.....	21.00
Total	\$84.83

A total of 82.2 cu. yds. of wall was built, the labor cost per cubic yard being \$1.03; the contract price was at \$1.25 per cubic yard.

If the full cost of the plant is charged to the work, another 33 cts. per cu. yd. must be added for plant.

The mortar was mixed 1 : 1, and Louisville (natural) cement was used, each bar being called 2 cu. ft.

The wall averaged 24 ft. high, and was 4 ft. wide for the upper 8 ft., then it widened to 12 ft. at the base. It was laid in courses 12 to 18 ins. thick.

Cost of Laying Bridge Pier Masonry.—Mr. Gustave Kaufman gives the following data on the abutments and piers of a highway bridge across the Ohio River at Cincinnati. The total length of the bridge is 2,966 ft., with a 24-ft. roadway and two 7-ft. sidewalks. There are two abutments, nine masonry piers, of which four piers are founded on limestone, and five on piles. There are 28 pedestals for the steel viaduct approaches. The center span of the bridge has a clear height of 102 ft. above low water. Work on the substructure was begun May 1, 1890, and floods caused many delays, so that the bridge was not opened till Aug., 1891.

Louisville cement was used throughout, except Portland cement for pointing. Piers Nos. 1, 2, 3 and 9 are Ohio River freestone, with a backing of freestone. Where pile foundations were used, the heads of piles were imbedded in 3 to 4½ ft. of concrete foundation. Piers 4 to 8, inclusive, are of Berea sandstone with a backing, or hearting, of concrete, up to the belt course, above which the masonry is Ohio River freestone entirely. The dimensions of the piers are shown in Table I.

TABLE I.—DIMENSIONS OHIO RIVER PIERS.

Pier No.	Size Under Coping. Feet.	Height Over All. Feet.	Size at Base of Shaft. Feet.	Cubic Yards Masonry.	Remarks.
1	5 × 30	26.2	6.4 × 31.4	146.2	Square shaft.
2	5 × 30	39.4	7.6 × 32.6	271.7	"
3	6 × 30	47.0	9.1 × 33.1	292.9	Circular shaft.
4	9 × 34	74.0	12.8 × 49.6	1,432.9	"
5	10 × 34	112.8	17.3 × 53.7	2,357.6	"
6	10 × 34	104.1	17.8 × 54.2	2,475.6	"
7	9 × 34	93.4	16.0 × 51.8	1,974.1	"
8	7 × 32	87.1	13.4 × 46.8	1,392.3	"
9	7 × 32	37.3	9.6 × 34.6	330.1	Square shaft.

Note.—Pier No. 3, height includes calson. The coping of all piers was Bedford oolitic limestone 18 ins. thick, except for piers 5 and 6 which had a 24-in. coping. There were 2,172 cu. yds. of masonry in the ramps on both sides of the river.

The masonry was laid with the help of derrick scows, and the cost of laying the 280 cu. yds. above the starting course was \$1.25 per cu. yd., including the cost of sand and cement. The cost of laying the sub-coping and coping was \$1.45 per cu. yd., including sand and cement. The cost of laying masonry and concrete, courses 6 to 21, was \$1.30 per cu. yd., including sand and cement. These costs do not include cofferdams. Wages were as follows, per 10-hr. day: Common labor, \$1.50; masons, \$3.25; stone cutters, \$3.50; enginemen, \$2.00; foreman, \$4.00.

The face stones were laid alternate headers and stretchers, stones being not less than 2½ ft. long, dressed to ¾-in. bed joints and

$\frac{3}{4}$ -in. vertical joints for at least 12 ins. back of the face. The width of each stone was $1\frac{1}{4}$ times the depth of the course.

The cost of laying Pier 5 was \$0.72 per cu. yd., courses 1 to 37; and \$1.11 per cu. yd., courses 38 to 54; and \$1.16 per cu. yd., courses 55 to 58; the cost of sand and cement is included in all cases. See Tables II and III.

Cost of Sodom Dam.—Mr. Walter McCulloch gives the following data on the Sodom Dam, on the east branch of the Croton River, N. Y. The dam is 500 ft. long at the coping, 240 ft. long at top of foundation, 52 ft. thick at foundation, 12 ft. thick under coping, and 78 ft. high above ground line. Work was begun Feb. 22, 1892, and completed Oct. 29, 1892. The contractor paid laborers \$1.25 a day, and masons, \$2.50. There were 35,887 cu. yds. of masonry of all classes. Of this 22,600 cu. yds. were rubble laid in 1:2 Portland mortar, 6,200 cu. yds. rubble in 1:3 mortar, 780 cu. yds. of granite dimension stone masonry, 4,300 cu. yds. limestone face masonry, and 520 cu. yds. of brick masonry. The face masonry and brickwork were laid in 1:2 Portland mortar. The rubble was quarried $1\frac{1}{4}$ miles from the dam and hauled on double team trucks carrying 1 to $1\frac{1}{2}$ cu. yds. per load, making 6 to 8 trips a day. The rock was a hard, close-grained gneiss of irregular cleavage. The face stones (4,300 cu. yds.) were quarried at a limestone quarry 7 miles away and delivered on cars of the N. Y. & N. E. R. R. These stones were cut for 30-in. courses, stretchers being $3\frac{1}{2}$ ft. long, and headers 4 ft. long. Dimension stones (780 cu. yds.) were granite from Wilmington, Del. Cement cost from \$2.21 to \$2.51 per bbl. The cost of the rubble stone delivered on the work from the quarry was \$1.97 per cu. yd., including 5 cts. quarry royalty. Rubble stone and spalls from the excavation waste banks cost \$0.67 per cu. yd. The average cost of rubble stone was \$1.26. The actual cost of rubble masonry in 1:2 mortar was \$4.45 per cu. yd. The actual cost of limestone for face work was \$9.75 per cu. yd., including 15 cts. quarry royalty, but not including laying and mortar. The cost of dimension granite on the work, including dressing, was \$30.08 per cu. yd. The cost of the coffer-damming and other work is not given.

A cableway spanned the dam, 2-in. cable, 7 lbs. per ft., 667-ft. span, sag 25 ft. under 10-ton load. The cableway plant cost \$3,800. After four months' use the cable, under a load of only 6 tons, broke 50 ft. from one tower, at a place where stone and cement skips were taken up. A new cable was installed, the towers raised 10 ft. so as to give it more sag, and it served till the end of the work. The cableway anchors were oak deadmen, 2 ft. diameter by 16 ft. long, in trenches in rock 6 ft. deep. The masonry was laid with fixed derricks and with a traveling derrick on a 20-ft. trestle running upon a track of 36-ft. gage. The best month's work was 3,000 cu. yds. laid with 12 masons and three derricks; the average progress was 1,700 cu. yds. per month. The Giant Portland cement came in duck bags of 100 lbs. each (92 lbs. net), four to the barrel. The Union natural cement came in 100-lb. bags (96 lbs. net), three

TABLE II. PIER No. 4—OHIO RIVER.

No. of course.	Size of course out to out, ft.	Thick-ness of stone, in.	Cu. masonry, yds. face.	Cu. yds. backing.	Cu. mortar in all joints, yd. face.	Face work per cent of whole, yd. face.	Bbls. cement per cu. yd. backing.	Remarks.

NOTE.--Between courses 1 to 33 the Louisville cement used was .33 bbl. per cu. yd.; courses 34 to 54 used .30 bbl. per cu. yd.; courses 55 and 56 used .35 bbl. per cu. yd.

Percentage of face work, courses 1 to 33 was 46.4%.

Percentage of face work, courses 34 to 54 was 55.8%.

Mortar was 1 to 2 throughout. There was one header to every three stretches, no face stone being less than 3 1/2 ft. long, and dressed to 1/2 in. joints. No spaces wider than 6 in. allowed between backing stones.

to the barrel. The sand and cement were mixed dry (3 turns with shovels) and delivered in boxes on the work where it was wet as needed. Rubble stones varied from 1 cu. ft. to 1 cu. yd. in size, and in placing them the beds of mortar were made very full and the stone thoroughly shaken till firm. Mortar was filled into the joints and then all the spalls that it would take were forced in. Care was taken not to build the rubble up in courses. In freezing weather, above 20°, hot brine (5 lbs. salt to 1 bbl. of water) and heated sand were used for the mortar. Salt and sand were sprinkled over the fresh mortar at night. In the spring the mortar laid in freezing weather could be scaled off 1/16 to 1/4 in. deep, but under this it was hard. In laying the foundation it was found that springs of water would wash the cement out of the concrete, so it proved better to lay beds of rubble made of small stones. The water could be led around the rubble and nured from place to place till finally a small well, 2 ft. in diameter and 1 to 2 ft. deep, would be formed where the water boiled up. When the mortar about each little well had set, the water was balled out, the well quickly filled with dry mortar, a bed of stiff wet mortar laid on top and covered with a large rubble stone. When the water was turned in behind this dam there were no leaks. This was in a large measure due to the use of rich mortar and careful work. No cracks developed.

Cost of Dams and Locks, Black Warrior River.—Mr. R. C. McCalla gives the following data relative to the cost of building masonry locks and dams on the Black Warrior River, Alabama. The work was done by hired labor for the government, in 1888 to 1895, at costs given in Table IV.

The stone is a sandstone quarried near the locks along the banks of the river and in the river bed. The stone for Lock and Dam No. 3 was quarried in a reef just above falls 7 ft. high. The quarry covered two acres, and was operated a depth of 12 to 18 ft. during low water, requiring only two 3-in. pulsometer pumps to keep it drained.

The face stone of locks Nos. 1, 2 and 3 were set in 1:3 Portland mortar (cement measured loose); the backing was partly set in mortar and partly in 1:3:5 concrete. Stiff-leg derricks were used to set the stones.

In October, 1891, 200 cu. yds. of backing and 600 cu. yds. of dimension stone were quarried for Lock No. 3, Black Warrior River, Tuscaloosa, Ala. The stone was a fine quality of blue sandstone quarried from the bed of the river at the falls, after diverting the water. The cost of quarrying these 800 cu. yds. was \$1,598, or about \$1 per cu. yd. for the backing and \$2.33 per cu. yd. for the dimension stone. In this month 434 cu. yds. of dimension stone were cut by stonecutters at a cost of \$6.83 per cu. yd. The masonry wall is 390 1/4 ft. long, 8 to 14 ft. wide, and 34 ft. high, built in courses of ashlar 18 to 24 ins. thick, and about 50% cut stone. In October two gangs of masons, using two derricks, laid 1,563 cu. yds. of first-class masonry at a total cost of 92 1/2 cts. per cu. yd., including the cost of screening sand, mixing mortar, operating steam

Note.—Dam No. 1 is 10 ft. high, 21 ft. wide at base, and 339 ft. long; No. 2 is 13 ft. high, 24 ft. wide at base, and 410 ft. long; No. 3 is 15 ft. high, 26 ft. wide at base and 650 ft. long.

hoists, unloading material at the wall and converting them into masonry. The itemized cost of the mason work was:

Foreman, 1 mo.	\$ 90.00
Masons, 202 days of 8 hrs., at \$2.80.....	585.60
Laborers, 25 1/2 days of 8 hrs., at \$1.20.....	42.15
Laborers, 270 1/2 days of 8 hrs., at \$1.00.....	270.50
Laborers, 369 1/2 days of 8 hrs., at \$0.80.....	295.70
Laborers, 146 1/2 days of 8 hrs., at \$0.60.....	88.05
Boys, 83 1/2 days of 8 hrs., at \$0.40.....	33.20
Wages paid in board.....	42.00
Fuel for hoists.....	18.49

Total, at 92 1/2 cts. per cu. yd.....\$1,445.79

It will be noted that the wages of laborers were very low. Doubtless the men were negroes.

On the south wall of Lock No. 2, Black Warrior River, during August, 1892, two gangs of masons, three masons to the gang, with helpers, laid and pointed 2,370 cu. yds., about 40% of which was dry rubble wall, the rest being first-class masonry in Portland cement mortar. This is 16 cu. yds. per mason per 8-hr. day. The following includes the cost of screening sand, mixing mortar, unloading materials at the wall, operating steam hoists, fuel for same, laying and pointing the masonry:

Foreman, 1 mo.	\$ 100.00
Masons, 147 1/2 days, at \$3.50.....	515.25
Laborers, 27 1/2 days, at \$1.50.....	41.25
Laborers, 108 days, at \$1.25.....	135.00
Laborers, 510 1/2 days, at \$1.00.....	510.50
Laborers, 216 days, at \$0.80.....	172.80
Laborers, 186 1/2 days, at \$0.75.....	139.83
Laborers, 103 days, at \$0.55.....	56.65
Boys, 87 1/2 days, at \$0.50.....	43.88
Wages paid in board.....	100.00
Fuel	22.75

Total, at 77.6 cts. per cu. yd.....\$1,838.96

Cost of Rock-fill Dams.—The three dams on the Black Warrior River, built by hired labor, were of the rock-fill type without mortar or core-walls. The down stream face is composed of large roughly dressed stones, laid in steps and doweled together. A timber crib is built into the upper face of the dam and sheathed with 6 x 12-in. plank. The dams were built during low water, without cofferdamming. Floating and stationary derricks were used. Sandstone for dams Nos. 1 and 2 was delivered by barge, and for No. 3 by rail, a track being laid on stone-filled cribs along the toe of the dam. The cost of this work is given in Table V.

	Crib No. 1.		Crib No. 2.		Crib No. 3.	
Lumber and iron Ft.B.M.	34,453	\$13.65	33,109	\$12.68	33,109	\$14.16
Carpenter work, Ft.B.M.	34,453	6.94	33,109	6.83	33,109	12.62
Filling rock ... Cu. yds.	1,640	0.35	1,105	0.24	1,090	0.46
Total		\$1,277		\$909		\$1,296

Note.—Crib No. 1 is 29 ft. 10 ins. high, 11 ft. 8 ins. wide, and 90 ft. long; Cribs Nos. 2 and 3 are 28 ft. 8 ins. high, 11 ft. 8 ins. wide, and 90 ft. long. The cribs are of 6 x 8-in. yellow pine with cross-pieces at intervals of 5 ft., drift-bolted together, and filled with one-man stone.

Cost of Cyclopean Masonry, Reference.—See the section on Concrete under Rubble Concrete.

Cost of Limestone and Sandstone Slope-Walls.—A slope-wall is practically a stone block pavement laid upon a sloping face of earth to protect it from erosion. The "wash" of passing boats in canals makes necessary some such protection of the earth in certain places. The beating of waves upon the sides of a reservoir or small lake acts in a similar manner, and a slope-wall is usually provided to resist the erosion. The concave side of a river bank is occasionally protected by slop-walling, with perhaps a line of piling at the toe of the wall.

A dry slope-wall, it will be seen, is an engineering structure often used, although very little exists in print as to its design or cost. Since the forces acting upon a slope-wall are not readily measurable, the design is an art, and not a science. Recorded ex-

Fig. 2. Slope Wall.

Fig. 3.

perience of others, personal experience of the designer and common sense should govern the design.

The oldest slope-walls on the Erie Canal were made of cobblestones rammed solidly into the bank, and placed so that the stones touched one another. Cobbles for this purpose were gathered from fields or creek beds, and ranged in diameter from 4 ins. to 12 ins., the average being about 6 or 8 ins. These cobble slope-walls, while not as handsome as those made of dressed quarry stone, were in fact more durable, for the shales and limestone ledges along the route of the Erie Canal furnish stone more or less subject to weathering. Cobbles, or "hardheads," on the contrary, are often granitic and always tough.

Slope-walls made of quarry stone are built as shown in Figs. 2 and 3. The stones are split with wedges or plug and feathered, then roughly dressed with a hammer, and placed in the wall on edge, just as brick or stone block are placed in a street pavement. The longest dimension of the stone is laid parallel with the axis of the canal or river. In some of the earlier walls, huge slabs of stone were laid flatwise just as sidewalk flagging is laid, but such stones are apt to settle unevenly and tilt up so that a passing boat or moving ice will displace them entirely. Moreover it is practically impossible to bed very large stone properly, since ramming has no

effect. Experience, therefore, has shown the necessity of splitting up slabs into blocks readily laid and bedded by hand; and it costs no more in the end to build walls in this way, for the cost of handling with a derrick and cost of frequent moving of derrick more than offset the cost of splitting the stone. It is customary on the Erie Canal always to provide a lining of gravel (Fig. 1) back of the wall. This lining serves a twofold purpose: It makes it easy for the workman to bed jagged stone properly, and it further adds to the protection of the subsoil from wash. Waves beating through the joints in the slope-wall strike this gravel which is not easily displaced, and do not reach the subsoil with sufficient force to displace it. It is my opinion that this gravel lining is one of the most important and necessary features of a well-made slope-wall. Crushed stone, of course, would serve equally well or better, but usually the cost is more than for gravel. There are places where broken stone costs less than gravel and in such places it should be used.

On rivers or reservoirs, subject to wide fluctuation in water level, the gravel or stone lining for the paving is even more necessary; for there the surface rain water, flowing down over the face of the slope-wall, will cut rivulets beneath it unless proper lining is provided. Embankments are usually so designed as to prevent much rain water from flowing over the slope-wall face, as shown in Fig. 1, where the towpath is seen to have a slope away from the canal. In diking a river the same form of top slope is usually provided where a slope-wall is to be laid; but in protecting a natural river bank it is often impossible entirely to prevent rain water from flowing over the face of the slope-wall. Ditches should be dug to divert the rain water, which is then carried in a pipe culvert through to the river. Ditches, however, are apt to fill up with washed-in earth, so that in any event a substantial lining of gravel should be placed back of the slope-wall, in order to guard against erosion by rain water. A thickness of gravel lining of from 4 to 8 ins. will suffice, 4 ins. ordinarily being enough.

Passing to the thickness of the stone slope-wall itself, we find a range of from 6 ins. to 24 ins. with 12 to 16 ins. most commonly used. The Chemung River, near Elmira, N. Y., is a stream about 600 ft. wide and 20 ft. deep in times of high water. At one place on this river a slope-wall 24 ins. thick was built by the State, and a few miles away another had been built 12 ins. thick, both of a shaley limestone. Both walls have served for years, except in places where the piling at the toe has been undermined. The 24-in. wall was evidently an extravagant design; and not justified by the conditions, particularly as the lighter wall had been in service some years before the construction of the 24-in. wall was begun. Because a river is occasionally a raging torrent it does not follow that the floating debris or ice will displace the small stones of a well-laid slope-wall. As a matter of fact, each stone is held by the weight of stones above, even when laid on a $1\frac{1}{2}$ to 1 slope, and a stone is pried out of a slope-wall with great difficulty. I believe

that ordinary brick laid dry as a slope-wall pavement will protect a river embankment perfectly, provided the subsoil does not become undermined. In slope-wall masonry, on river embankments subject to blows of ice and logs, a thickness of 8 to 10 ins. seems an advisable minimum, for some erosion and settlement of the subsoil or lining must be provided for. On reservoirs or canals a less thickness may be used where blows from boats are not frequent. But as above stated 12 ins. is very often specified, and as will be seen later, it is not an extravagant depth. Having fixed upon the depth of stone to be used in the wall, the thickness (or rise) and length remain to be determined. A minimum thickness of 4 ins. is usually specified. As a matter of fact, except for appearance sake, thickness is not an important factor. An engineer who is fond of seeing coursed masonry will often require that the slope-wall be laid in courses of a specified minimum and maximum thickness. It costs money to dress the stone to lay in such courses, but for appearance sake, near a highway, such expense may be justified. Ordinarily it is not justifiable. Slope-walls are built for protection, not for beauty.

If any definite minimum thickness of courses is specified, it should be governed by the stratified thickness of stone in the nearest quarry. If the quarry is thick-bedded limestone, then it is safe to omit any minimum thickness requirement; for to split into thin slabs with plug and feathers is expensive, and the contractor will surely not split the stone thinner than the maximum thickness specified. If the quarry stone is thin-bedded, as shaley limestone and some sandstones are, a minimum thickness of 3 or 4 ins. may be named. A maximum thickness of 10 or 12 ins. is a reasonable requirement. A minimum length of 12 ins. is often specified, and is not unreasonable, for slabs are readily broken with a hammer to almost any desired length. There is no objection to stones up to 24 ins. in length.

Slope-wall paving is "laid to break joint," as shown in Fig. 3, and it is well so to lay it, because if the toe is washed out, this breaking of joint enables the wall above to span the space, and so prevents rapid crumbling away of the wall. However, specifications are often drawn with absurd refinement as to this bonding; the least admissible number of inches of bond is named, and altogether the wall is treated as if it were to be a bridge pier, or arch, or other necessarily strong structure. To require that the stones shall be laid so as to break joint is a sufficient requirement for slope-wall work.

We come now to the feature of the specifications that makes a wall cost little or much—the allowable maximum width of bed and end joints. Specifications sometimes name $\frac{1}{2}$ -in. joints to the full depth of each stone. Such work, as we shall see, costs twice as much as under the more reasonable requirement of $1\frac{1}{2}$ -in. joints, carried back 4 ins. from the face beyond which the stone may fall away to a wedge shape. To call for joints of less than $1\frac{1}{2}$ ins. is justifiable only where well coursed slope-wall is desired for

appearance sake. Wall with 1½-in. maximum joints serves the purpose of protection from erosion, and any expense incurred in better dressing is merely "for looks."

In laying a slope-wall, "frames" or "profiles" should be set about 20 or 25 ft. apart, as shown in Fig. 4. Stakes are driven as shown, and a 1 x 4-in. profile-stick of timber is nailed to the stake at the proper grade, as determined by the Y-level. The workmen then stretch a string from the bottom of one frame to the bottom of the next one, and thus have a line to which they can accurately lay the face of the slope-wall. Never allow a workman to attempt to lay slope-wall without such frames and a cord to guide him; for without such guides he will surely lay a wall with humps and hollows. Another point in practical laying is always to incline each stone lightly uphill. Do not try to set it exactly at right angles to the surface of the ground, for an endeavor to do this results in a wall like that in Fig. 5, where the stone are in steps.

Fig. 4. Profiles.

Fig. 5.

Fig. 6.

It is an excellent plan to set the profile strips exactly 12½ ft. apart, for reasons given later on.

The stone are split with plug and feathers and hammers in the quarry, hauled by wagons and dumped at the top of the embankment as in Fig. 4. Laborers then throw the stones down to the slope-wall masons, who roughly scabble and lay them, filling in the chinks back of the face with spalls and gravel lining. An intelligent laborer can soon learn to lay common slope-wall, but skilled slope-wall masons, if available, usually lay a better-appearing wall at less cost. Sharp-pointed stones like A, Fig. 6, should ordinarily not be allowed; but stones like B, that are roughly dressed, 3 to 4 ins. back of the face, and then fall away so as to leave a wide end joint as shown, are not objectionable, provided these joints are filled with spalls and gravel.

Before passing to a consideration of costs, a word should be given as to protecting the toe or foot of the wall. In canal work it is customary to lay a 12 x 12-in. toe-timber or stick, as shown in Fig. 4. Since timber continually submerged does not rot, and

since frozen timber in the winter when canals are closed does not rot either, this design is not objectionable for canals. However, I question the necessity of using a toe stick at all under ordinary conditions in canal work. In river work, a toe stick resting against piles driven 5 ft. c. to c., is often used. In some cases the toe stick is done away with entirely and a line of close-driven piles substituted, which is a very expensive solution of the problem and not altogether satisfactory. Piling on the concave bank of a river seems to hasten rather than retard undermining. A brush mattress is a better toe protection under such conditions, and heavy rip-rap is still better where the brush is alternately wet and dry.

The following are actual costs of work that I have done. The quarry required very little stripping, and was located on a side hill, $2\frac{1}{4}$ miles from the work. The stone was a thin bedded limestone, rather shaley, and was barred and wedged out with the use of little or no powder. There was very little plug and feathering as the stone split readily under the hammer. Common labor was employed, the only skilled man being the foreman, who worked with the men.

One hundred and forty wagon loads of stone, each load measuring 2 cu. yds. corded upon the wagon, and 1.55 cu. yds. laid in the slope-wall, making a total of 220 cu. yds. in the wall, were quarried and loaded by five men (including the foreman) in 20 working days of 10 hrs. each, or at the rate of 2.2 cu. yds. of slope-wall quarried per man per day. Laborers received \$1.50 a day and foreman \$2.50, so the wages averaged \$1.70, which, divided by 2.2, makes the cost nearly 80 cts. per cu. yd. for quarrying and loading the stone. Each driver helped load and unload his wagon, and hauled 4 to 5 loads a day. A team and driver received 70 cts. a load for hauling (5 miles round trip) over a good hard gravel road with no upgrades; so the cost of hauling was about 45 cts. per cu. yd. of slope-wall, making a total of \$1.25 for the stone delivered at the work. A quarry rental of 10 cts. per cu. yd. was paid for the stone. To estimate the cost of loading and hauling for other distances the following observations were made: Two laborers working quite deliberately handed up the stone to the driver, who stacked them on his "stone rack" (3 x 11 ft.), or wagon box without sides other than a strip of 4 x 4-in. timber. It required 15 mins. to load a wagon with 2 cu. yds. measured on the wagon, or 1.55 cu. yds. in the slope-wall. The driver alone would unload his wagon at the dump in 7 mins., by simply rolling the stone off.

The team traveled at a speed of $2\frac{1}{4}$ miles an hour, or 220 ft. a minute, at a walk, and generally trotted part of the way back to make up for lost time at both ends. With a short haul, or over soft roads trotting would have been out of the question; and over very soft earth roads with occasional steep pulls a load half as great as the above is the maximum.

On another similar contract 750 cu. yds. of slope-wall were quarried at a cost of \$1.10 per cu. yd., the stone being a "grit" or shaley limestone, quarried by laborers at \$1.50 per day of 10 hrs.

The haul was $1\frac{1}{2}$ miles from quarry to wall and 6 trips a day were made by each team, hauling $1\frac{1}{2}$ cu. yds. each trip as measured in the wall, at a cost of 35 cts. per cu. yd. for hauling. This stone, therefore, cost \$1.45 per cu. yd. delivered.

In laying 750 cu. yds. of "second-class" slope-wall, 12 ins. thick, joints $1\frac{1}{2}$ ins. as a maximum, stone allowed to fall away 4 ins. back of face, not laid in courses, but an excellent wall in appearance and in reality, the cost was as follows: The first few days, using new hands, intelligent laborers, each man laid $2\frac{1}{2}$ cu. yds. at a cost of 60 cts. a cu. yd., wages being \$1.50 per 10-hr. day. Later these men readily averaged 3 cu. yds. per day. Some skilled slope-wall layers were imported and received \$2.50 per 10-hr. day. These men readily laid 6 cu. yds. each day, one laborer to every four slope-wall layers acting as a helper to deliver stone. Thus 600 cu. yds. of slope-wall were laid in 120 layer-days and 35 helper-days, half of the layers being skilled men, and half common laborers. There was no foreman in constant attendance, as each man's work between the frames was easily measured up, and his daily progress thus known. A portion of the work was sublet at 50 cts. per cu. yd. to two of the skilled slope-wall masons who had each been averaging 5 cu. yds. a day. From that time on each averaged $7\frac{1}{2}$ cu. yds. of wall daily. Skilled men like these under subcontract will lay 10 or even 12 cu. yds. of a somewhat rougher slope-wall in 10 hrs. On another contract where the wall was 16 ins. thick, 4 masons at \$2.50 and 4 laborers at \$1.50 averaged 60 cu. yds. of fair slope-wall per 10-hr. day. Work was scarce, and one of the masons was the subcontractor himself, and received 30 cts. per cu. yd. Assuming 50 cts. per cu. yd. as a fair average cost for laying good "second-class" slope-wall and \$1.25 to \$1.50 for cost of stone delivered, we have a total cost of \$1.75 to \$2.00 per cu. yd. in place.

The average contract price for slope-wall on the Erie Canal deepening in 1896-7 was \$2.50 per cu. yd., wages being as above given. Slope-wall laid in courses, with close joints the full depth of the wall, no course less than 6 ins. thick—a sand-papered job—was let for \$4.50 per cu. yd. under conditions where \$2.50 was a fair price for good ordinary slope-wall. The actual cost was not far below the contract price for stone plug and feathered to size cost delivered \$2.50 per cu. yd., and laying cost \$1.25 per cu. yd. Gravel lining in both cases was paid for separately, the contract price along the Erie Canal averaging 30 cts. per cu. yd. of lining in place. The actual cost of this lining is of course figured as for any earthwork, an allowance being made for spreading it on the face of the embankment after dumping it. To spread it most expeditiously it will pay to make a wooden chute into which the gravel is shoveled from the wagons, a shoveler helping the driver to unload. Two men will unload 1 cu. yd. in this way in 10 minutes, if they work as they should. The driver then has a rest on his return trip, at the end of which it is well to provide an extra wagon, which has been loaded during his absence. It takes only

1½ min. to change the team from the empty to the loaded wagon. Since 1 to 1½ cu. yds. of gravel constitute a load, since teams travel 220 ft. per min., and since a laborer can load 12 cu. yds. of gravel in 10 hrs., we have all the factors necessary to compute the cost of hauling and unloading. There is very little work in spreading the gravel where a chute is used, 2 to 5 cts. per cu. yd. covering this item.

If good thin-bedded sandstone or limestone is not available, it may be necessary to plug and feather the stone to sizes specified, and this cost may be estimated by data on page 492.

In order to secure the most economic results, slope-wall masons should be paid on the bonus system. To do this, the profile strips are set 12½ ft. apart, so that every lineal foot on the strip means ½ cu. yd. of slope-wall, if the wall is 1 ft. thick. Each mason is assigned to one lot, between two profile strips, and the lots are numbered consecutively with red chalk marks on the posts. The profile strips are of 2 x 4 dressed pine, painted with foot marks, so that a timekeeper can see at a glance the height to which the wall in any given lot has reached at the end of the day. There is no measuring to be done after the strips are nailed in place, yet the timekeeper and the masons themselves can keep a perfect record of daily progress. After the work has been under way a short time, it will be evident that a laborer to every two masons, say, will be necessary to deliver stone down the slope. At first the average output is but little better than before, but certain of the masons will do much better than the average. Their wages are then increased and perhaps two or more of the slower masons are discharged. Immediately, if there are no unions to interfere, the output of the men increases. At the end of a week I have had the average yardage increase 50%, and individual yardage increase much more, the quality of the workmanship remaining as before. The men receive higher wages and the contractor increases his profits, both by virtue of the greater output and by reducing the cost of supervision. I have been away from such work, after organizing it, for two weeks at a time, without a foreman in direct charge, yet the output has not fallen off. A more effective plan than merely to increase the daily wage is to pay a bonus per cubic yard for every yard in excess of, say, 2 cu. yds. laid per day.

Cost of Granite Slope-Wall.—The cost of a granite slope-wall greatly exceeds the cost of slope-walls of stratified rock such as are described in the preceding paragraphs, if any attempt is made to square the granite slope-wall stones, for rubble granite stones must be plug and feathered on all faces to square them up. Even where the specifications are lenient, if an attempt is made to secure a granite slope-wall with a smooth face, but without close joints, the cost of plugging off the faces of stone before laying, and the cost of reducing them to a size not greater than the thickness of the wall (12 to 18 ins.) is not a small item. If granite boulders, or granite rubble stones from a quarry, are to be used, first estimate

roughly the average size of each stone, then estimate the number of plug-holes necessary to split it into slope-wall stones. Use the data on page 492 for estimating the cost of this plug and feather work.

On one job of granite slope-wall work, 3 masons splitting field boulders with plugs, and 10 laborers laying a wall 18 ins. thick, averaged 14 cu. yds. per day of 10 hrs. for \$24, or \$1.70 per cu. yd. for splitting and laying the stones. No attempt was made to secure close joints or to lay the stone in courses. Stones were frequently laid flatwise and bedded in spawls; and spawls were used liberally between joints. The masons were rapid workers, but the laborers were a slow lot of men.

Cost of Laying a Limestone Slope-Wall.—Mr. W. B. Fuller says. "The paving of the upper sides of the sedimentation basin (Albany, N. Y.) is of blue limestone blocks, 10 to 15 ins. deep, 8 to 20 ins. wide, and 15 to 26 ins. long. Two masons and one helper together would lay about 16 sq. yds. per day, and the labor cost of laying the stone and gravel, including the teaming of the material about 800 ft., was 72 cts. per sq. yd."

The specifications called for a slope-wall 10 ins. thick laid on a gravel lining 24 ins. thick.

Cost of Slope Wall Paving.*—Maj. Graham D. Fitch gives the following:

In paving the bank of the Upper White River, selected sandstone (bluestone) was used, the pieces being set on edge and rammed. A coat of gravel was then swept over the paving. The work was done by Government forces; common laborers receiving \$1.50 for 8 hrs.

The cost of grading and paving behind the land wall was as follows:

Material	Unit cost.	Total	Per sq. yd. Paving.
Riprap stone, 798 cu. yds.....	\$0.74	\$590	\$0.307
Cement, 6 bbls.	1.97	10	.006
Total materials		\$600	\$0.313
Labor:			
Insp. of riprap stone, 798 cu. yds.	\$0.008	\$6	\$0.003
Insp. of cement, 6 bbls.022	.44	.002
Grading and paving 1,916 sq. yds.	.496	947	.493
Total labor		\$953	\$0.496
Grand total, 1,916 sq. yds.....		\$1,553	\$0.810

The total labor time for the 1,916 sq. yds. of grading and paving was 550½ days, the work done per man per day being 3.49 sq. yds., or 1.45 sq. yds.

It will be noted that 1 cu. yd. of stone made 3.4 sq. yds. of

**Engineering-Contracting*, May 6, 1903, p. 233.

pavement, showing that the thickness was 15 ins. The labor of grading and paving was \$1.18 per cu. yd.

At another place the cost of slope-wall pavement was as follows:

Material:	Unit cost.	Total.	Per cu. yd.
Riprap, 693 cu. yds.....	.74	\$513	\$0.74
Labor:			
Paving, 425 days.....		\$335	\$1.20
Inspection of riprap, 8 days.....		15	.02
Total		\$850	\$1.96
Grand total, 693 cu. yds. placed....		\$1,363	\$1.96

The amount of paving done per man per day was 1.16 cu. yds.

At another place the cost was:

	Unit cost.	Total.	Per cu. yd.
Riprap, 438 cu. yds.....	\$.74	\$324	\$.74
Labor, 293½ days.....		374	.86
Grand total, 438 cu. yds.....		\$698	\$1.59

The average work done per man per day was 2.1 cu. yds. of riprap placed.

Cost of Riprap on a River Bank.*—Maj. Graham D. Fitch gives the following:

The work was done on the Upper White River, by Government forces, common laborers receiving \$1.50 per 3-hr. day. Sandstone was used.

The following was a piece of bank revetment, the riprap being laid roughly by hand to a depth of nearly 12 ins. There were 3,588 sq. yds.:

	Unit cost.	Total.	Per sq. yd.
Riprap, 1,235 cu. yds.....	\$0.74	\$914	\$0.254
Inspection of riprap, 1,235 cu. yds..	.002	10	.002
Placing riprap, 1,235 cu. yds.....	.245	302	.084
Total		\$1,226	\$0.340

The labor time for placing the 1,235 cu. yds. of riprap was 156 days, and each man placed an average of 7.92 cu. yds. of riprap per day. On the basis of 3,588 sq. yds. of revetment each man placed an average of 2.3 sq. yds. per day.

At another place riprap was placed on a brush mattress for bank revetment. The bank thus protected was 450 ft. long by 44 ft. wide (measured along the slope). The bank was graded by 124 man-days, at a cost of \$229, or 18 sq. yds. per man-day.

The cost of riprapping the bank was as follows.

	Unit cost.	Total.	Per cu. yd.
Riprap, 1,044 cu. yds.....	\$0.74	\$768	\$0.74
Paving, 109½ days		206	.197
Inspection of riprap, 14 days.....		26	.024
Grand total, 1,044 cu. yds.....		\$1,000	\$0.96

The work done per man per day was 8.43 cu. yds. of riprap placed.

*Engineering-Contracting, May 6, 1908, p. 288.

There were 2,200 sq. yds., hence the cost per sq. yd. was 9.4 cts. for labor, and 35 cts. for stone.

Cost of Riprap and Brush Mattress, Cross-Reference.—Data on this will be found in the section on Timberwork. Consult the index under "Brush Mattress."

Cost of Riprap in a Crib Dam.*—Maj. Graham D. Fitch gives the following:

The work was done on the Upper White River, by Government forces, common laborers receiving \$1.50 for 8 hrs. The stone was sandstone.

In filling the pockets of a crib dam 324 ft. long, 8,000 cu. yds. of riprap were used, at the following cost:

	Per cu. yd.
Riprap stone	\$0.74
Labor filling crib	0.43
Total	\$1.17

Each laborer averaged 4 cu. yds. filled per day.

On a small crib near one abutment of the dam, 527 cu. yds. of riprap were put in at the rate of 4.45 cu. yds. per man-day.

On a foundation crib for the abutment of the dam, 876 cu. yds. of riprap were put in at the rate of 8.84 cu. yds. per man-day.

Cost of Riprapping Cribs.†—The following data relate to the cost of riprapping cribs with breakwater stone at Ashtabula Harbor, Ohio. The stone was loaded from the dock into a derrick scow by the derrick, the scow was then towed an average of one-fourth mile and the stone placed, as riprap, behind new crib docks which had just been completed. The object of this crib backing was to protect the cribs from storms and also to relieve them of any lateral thrust which might cause them to move. The derrick scow used in handling the stone holds a maximum deck load of about 125 tons. The derrick boom is about 50 ft. long and all movements of the derrick are operated by steam.

The stone was placed in a mound of a triangular cross-section against the cribs, the apex of this right-angle triangle being at the water surface. The depth of water at the site of work averaged about 15 ft.

The stones used were irregular in shape, weighing 160 lbs. per cu. ft., the total average weight of each stone being about one ton.

The cost records below are for the months of May and June, 1907, and embraces the entire operation of riprapping the cribs, the work including: Loading the stone from the dock onto the deck of the scow; towing the scow from the dock to the site of the new cribs, an average distance of about one-fourth mile; unloading the stone behind the cribs as riprap; towing the scow from the

**Engineering-Contracting*, May 6, 1908, p. 285.

†*Engineering-Contracting*, July 31, 1907.

cribs back to the dock to be loaded again; time due to bad weather and breakdowns, interest and depreciation on value of plant and miscellaneous expense.

The scale of wages per 10-hr. day was as follows:

Foreman (who was also steam engineer).....	\$3.00
Deck hands	2.00
Watchman	1.75

The cost of backing the cribs with breakwater stone for month of May, during which time 461 tons of stone were placed, was as follows:

	Total.	Per ton.
10 transfers by tugs, at \$5.....	\$ 50.00	\$0.075
4 tons coal, at \$2.70.....	16.20	.024
Labor, placing stone.....	47.15	.071
Lost time due to bad weather and breakdowns..	31.60	.048
Interest and depreciation on value of plant.....	90.00	.136
Miscellaneous	10.00	.015
Total	\$244.95	\$0.269

The cost of backing the cribs for the month of June, during which time 1,380 tons of stone were placed, was as follows:

	Total.	Per ton.
24 transfers by tugs, at \$5.....	\$120.00	\$0.087
17 tons coal, at \$2.70.....	45.00	.032
Labor, placing stone.....	189.15	.140
Lost time, due to bad weather and breakdowns..	42.60	.030
Repairs and miscellaneous.....	38.55	.042
Interest and depreciation on value of plant.....	90.00	.065
Total	\$645.20	\$0.397

In the above tables the item "placing stone" includes the loading of stone on the scow from the dock and placing it behind the cribs. The labor cost of these two portions of the work were about equal. Interest and depreciation on plant was taken as 15% per annum and was distributed over five months. The item "miscellaneous" includes wages of watchman on Sundays, and a few supplies, such as engine-oil, waste, manila lines, etc. The repairs shown in the record for June consisted of repairing the damage due to a boom being dropped by accident and breaking in two.

On the basis that the weight of the stone was 160 lbs. per cu. ft., the cost per cubic yard for riprapping the cribs was as follows: Month of May, 80 cts.; month of June, 85 cts.

For the above information we are indebted to Mr. El. C. Bowen, Jr., Assistant Engineer, Lake Shore & Michigan Southern Ry.

[For further data on riprap, see the index under "Riprap."]

Cost of Riprap Stone, References.—For the cost of quarrying and handling stone see the sections on Rock Excavation and on Stone Masonry. Also consult the index under "Riprap," for contract prices of riprap are given in the section on Railways and elsewhere.

Cost of Cleaning Masonry With Acid.—Mr. C. M. Saville gives the following relative to the cost of cleaning masonry with acid.

The granite ashlar masonry of a reservoir gate chamber had been pointed with 1:1 Portland cement mortar late in the fall, during very cold weather. In order to work quickly the pointing mortar was mixed very wet, and consequently dripped over the ashlar, giving an unsightly appearance. In the spring, the pointing was removed, the stone washed with acid, and then repointed. About 560 sq. yds. of stone facing were thus gone over in 9 days by 2 men at a total cost of \$50, or 9 cts. per sq. yd. for labor. Dilute muriatic acid was used, 1 part acid to 2 parts water, applied with old paint brushes; 4 gals. of acid were required, or 1 gal. for 140 sq. yds. The two men were engaged 5 days removing pointing, 2 days cleaning stone, and 2 days repointing.

For other data, see the index under "Masonry, Cleaning."

Cost of Excavating Masonry.—The masonry abutments of an old bridge were removed to make way for a new arch bridge. A hand-power derrick was used, and the material was piled near the derrick. The cost of excavating this masonry was 50 cts. per cu. yd., wages being 15 cts. per hr. In another similar case the cost was 75 cts. per cu. yd. The average contract price for such work on the Erie Canal, in 1896, was 80 cts. per cu. yd., wages being 12½ cts. per hr.

Mr. C. R. Neher informs me that the cost of excavating 3,140 cu. yds. of old railway bridge piers, and depositing the material in the river bed, was 38 cts. per cu. yd., not including the cost of scaffolding.

For other data on masonry excavation, see the index under "Masonry, Excavation."

Cost of Pointing Old Bridge Masonry.—Cleaning and pointing old masonry, using Alpha cement at \$2.40 per bbl., masons' wages being \$2 and helpers \$1.60 per day, cost as follows:

Small jobs; no staging:		Cts. per sq. ft.
Cement		0.26
Labor		0.74
Total per sq. ft.....		1.00

This is equivalent to 9 cts. per sq. yd.

Large jobs; staging used:		Cts. per sq. ft.
Cement		8.27
Labor		1.87
Total per sq. ft.....		2.14

This is equivalent to 19 cts. per sq. yd.

For other similar data, see the index under "Masonry, Pointing."

Cost of Lining Tunnel With Masonry.—Drinker gives the following data on the lining of Carr's Tunnel (825 ft.) on the Pennsylvania R. R. in 1868-1869:

Brickwork.—Six hundred and nine thousand brick in the arch (5% broken and lost); 10.44 bushels of neat cement (no sand used in the mortar) laid 1,000 bricks, the mortar forming 30% of the

brick masonry; the arch was 25 ins. thick, 34½-ft. span and 9-ft. rise:

	Cost per M.
Bricks, f. o. b.....	\$ 8.80
Loss in handling	0.51
Unloading and delivering.....	1.93
Laying	5.84
Cement	5.10
Total	\$22.17

Bricklayers received 40 cts. per hr.; helpers, 17½ cts. per hr.; carpenters, 27½ cts. per hr.; laborers, 17 cts. per hr.

Stonework.—One thousand seven hundred and thirty perches (26 cu. ft.) of rough masonry for side walls, presumably sandstone; 187 perches of ring stone; 25 perches wasted in dressing. The bench walls were 4 ft. wide at the bottom, 3 ft. at the top and 13 ft. high:

	Cost per perch.
Quarrying (1,730 perches).....	\$ 4.80
Cutting (1,730 perches).....	4.36
Hauling (1,942 perches).....	1.06
Handling and laying (1,917 perches).....	3.80
Cement, 1.65 bu. per perch (81/8% of the masonry)	0.81
Total	\$13.83

Stonecutters and masons received 35 cts. per hr.; quarrymen, 17½ cts. per hr.; laborers, 17 cts. The stone side walls were laid in 2 courses averaging 2 ft. thick each; hence there were 52,800 sq. ft. of beds cut; and estimating each stone 3 ft. long and dressed for 1½ ft. back of the face on joints, there were 14,300 sq. ft. of joints; making a total of 67,100 sq. ft. of cutting which cost 11.2 cts. per sq. ft. This is said to have been too high a unit cost, and the accuracy of the measurements is questioned.

Arch centering cost \$1,400, to which was added \$600 for moving the centering forward from time to time; making \$2.40 per lin. ft. of tunnel, to which must be added \$0.70 per lin. ft. for scaffolding.

For further data on tunnel lining, see the index under "Tunnel, Lining."

Cross-References.—Other data on stone masonry will be found in various parts of this book, for which see the index under Masonry.

SECTION VI.

CONCRETE AND REINFORCED CONCRETE CONSTRUCTION.

Definitions.—See also the definitions in Section V on Stone Masonry.

Aggregate.—The broken stone or gravel used in concrete. The word *ballast* is also used in this sense.

Batch.—The amount of concrete mixed at one time either by a gang of men or by a machine mixer. In hand mixing, ordinarily one barrel of cement and the proper proportions of sand and stone make a batch.

Cement.—A preparation of calcined clay and limestone, or their equivalents, possessing the property of hardening into a solid mass when moistened with water. This property is exercised under water, as well as in open air. Cements are divided into four classes: Portland, Natural, Pozzolan and Silica cement.

Portland cement is the finely pulverized product resulting from the calcination to incipient fusion of an intimate mixture of properly proportioned argillaceous and calcareous materials, and to which no addition greater than 3% has been made subsequent to calcination.

Natural cement is the finely pulverized product resulting from the calcination of an argillaceous limestone at a temperature only sufficient to drive off the carbonic acid gas. A few years ago it was common practice to give to all natural cements the name Rosendale cement, for it was at Rosendale, N. Y., that the first natural cement was made in this country.

Pozzolan is an intimate mixture of pulverized granulated furnace slag and slaked lime without further calcination which possesses the hydraulic qualities of cement.

Silica cement (or sand cement) is a mixture of clean sand and Portland cement ground together.

Concrete.—An artificial stone made by mixing cement mortar with gravel or broken stone. The proportions of cement, sand and stone are generally expressed in parts by measure (occasionally by weight). A 1:2:5 (one, two, five) concrete means 1 part cement to 2 parts sand to 5 parts stone. A 1:3:6 concrete is made of 1 part cement, 3 parts sand and 6 parts stone (or gravel). When both stone and gravel are used, the concrete may be desig-

ated thus, 1:3:2:4, which means 1 part cement, 3 parts sand, 2 parts gravel and 4 parts stone.

Dry concrete is a term used to designate a mixture containing so small a percentage of water that very hard ramming is required to flush the water to the surface.

Wet concrete contains so much water as to require little or no ramming. "Sloppy concrete" is concrete so wet that it will run down a slightly inclined trough.

Concrete that is mixed *dry* is spread in layers 6 or 8 ins. thick and rammed or *tamped* until the water flushes to the surface. Concrete that is mixed *wet* is *spaded* with a spade-like tool that is worked up and down in the concrete to remove all air bubbles particularly near the forms or near any steel used to *reinforce* the concrete.

The terms *crushed stone* and *broken stone* are used indiscriminately to designate stone that has been broken by a rock crusher.

Crusher run means all the crushed stone just as it comes from the crusher, without separation into sizes, and generally it includes the product that would be termed screenings if it were screened out.

Facing.—(1) A rich mortar placed on the exposed surfaces to make a smooth finish. (2) Shovel facing by working the mortar of concrete to the face.

Forms are the molds (usually of lumber) that hold the concrete in shape until it has *set* or hardened.

Matrix is a term sometimes used instead of mortar, but there is no good reason for using the term at all.

Molds.—See *Forms*.

Reinforced concrete is concrete in which are embedded bars or wires of steel or iron. It is often called *concrete-steel*.

Rubble concrete is a term applied to concrete in which large rubble stones, or *plums*, are embedded. Stones from the size of a man's head to the size of a barrel are thus used. When larger stones are used, and the concrete becomes simply a coarse grained mortar between them, probably the term *cyclopean masonry* is more correct than *rubble concrete*; still there is no distinct dividing line.

Screenings applies to the product of the crusher that passes through the smallest screen used. The size of the smallest hole in the screen varies from $\frac{1}{8}$ -in. to $\frac{3}{4}$ -in., so the word screenings has no definite meaning, although it can usually be taken to apply to all stone under $\frac{1}{2}$ -in. in diameter.

Sylvester wash.—A waterproofing wash consisting of alum and soft soap applied alternately to the surface of concrete.

Voids is a term applied to the spaces between the grains of sand, or to the spaces between the fragments of broken stone. The voids are expressed in a percentage of the total volume of the loose material.

Magnitude of the Subject and General Discussion.—I have spoken of earth excavation as being a subject of great magnitude. But

the subject of concrete is even greater. This is well indicated in the citation even of a few of the important books on concrete which will be found at the end of this section.

Mr. Charles E. Hill, of the editorial staff of *Engineering-Contracting*, and I have collaborated in writing a 700-page book* devoted solely to the methods and cost of concrete and reinforced concrete construction. Yet there is practically no duplication in our book of the matter in Reid's great treatise, "Concrete and Reinforced Concrete Construction," in whose 900 pages the subject of the design of concrete construction is elaborated.

It will be evident, therefore, that in the space devoted to concrete in this handbook, only the principles of the methods and cost of construction can be given, supplemented by a few illustrative examples. However, the reader will find a good many more examples in other sections of the book, notably the sections on Bridges, Sewers, Waterworks, Pavements, and Buildings, for which consult the index under "Concrete."

While, at first glance, estimating the cost of concrete may seem difficult, it is in reality a comparatively simple task when the cost is divided into separate items and sub-items. Then the reason why the concrete base of a pavement costs say, \$2.50 per cu. yd., while the cost of a reinforced concrete building is, say, \$15 per cu. yd., is made very clear.

In considering variations in published cost data one should always bear in mind that there are not only many different ways of doing the same thing, but that workmen vary greatly in efficiency. The latter element depends mainly on the management, and it is a particularly important factor in this comparatively new branch of engineering work—concrete construction. I have received several letters from experienced concrete contractors questioning the accuracy of certain costs of concrete work that I had published, because, it was said, no such low costs had ever come under their observation. This was doubtless true and it was for just that reason that I had published those low costs; for, accompanied by the methods of doing the work, those records showed what thoroughly efficient workmen under good management could accomplish. I go so far as to say that unit costs of concrete work that are now regarded as being very low will, before long, seem exceedingly high—unless it should happen that rates of wages and prices of materials rise sufficiently to offset entirely all improvements in machines, methods, and management.

There is not the slightest doubt, for one thing, that we are using too much cement in most of our concrete. Rarely do we see American specifications requiring less than 0.2 bbl. of cement per cu. yd., although there are many classes of heavy concrete work for which 0.5 to 0.6 bbl. of cement per cu. yd. would suffice.

We have excellent machines for mixing concrete, but compara-

*"Concrete Construction—Methods and Cost," by Gillette and Hill.

tirely few contractors know how to transport the materials to and from the mixers with any great degree of economy.

Not only do poor designs of forms, but inefficient workmanship in framing, erecting and shifting them, usually run up the cost of formwork far above what it should be. Incidentally I may say that it is my opinion that the oft-berated method of intrusting both the design and erection of concrete buildings to firms of constructing engineers is a method that is likely to grow more popular. In spite of the objection that the designer should not be also the contractor for the structure, there is one very important element to consider, and one that seems to me to offset entirely any objection. *The concrete contractor who is also a designer will so design as to be able to use his forms again and again on many different buildings of the same character.* Eventually this will lead to the wide use of steel forms for certain classes of work, and thus reduce the item of form cost still more.

The manufacture of concrete in slabs, beams, boards, etc.—a sort of concrete lumber—is certain to become common, and will greatly reduce the cost of many classes of concrete work. Why, for example, should not rough retaining walls be built of concrete beams, or sticks, exactly as timber bulkheads are now made on railway work in timbered countries? By casting dovetailed shapes on the ends of the sticks, and corresponding recesses in other beams, it would be a simple matter to build such a concrete retaining wall of concrete, say 8 x 12 ins., in cross-section, with "anchors" of similar concrete sticks extending back into the earth filling that is placed back of the wall. In this manner a wall only 8 ins. thick, with each course anchored to the earth fill, could be built by unskilled laborers at a very low cost. The concrete sticks would be made in a yard, hauled to the site of the work, and erected with a light A derrick or moved on "dolleys" up an incline, just as heavy timbers are now handled.

In spite of the questionable success, thus far, of reinforced concrete cross-ties for railways, there is abundant reason to believe that such ties will eventually be perfected, thus leading to the making of concrete lumber in great quantities.

I am satisfied that thin concrete slabs, both in the form of concrete lumber and made in place by plastering mortar upon a reinforcing sheet or mesh, are destined to play a very important part in the construction field. Flues for carrying hot smelter gases have been made of expanded metal plastered on both sides with cement mortar. Why should not tall smokestacks be made in the same way? It might be necessary to give a large flare to the base, Eiffel Tower fashion, in order to secure stability when anchored to a concrete base. The great advantages of this method of plastering cement mortar upon a steel skeleton are two: (1) The ability to build concrete work without any forms at all; and (2) the ability to secure an exceedingly thin structure of great strength and durability.

With these and kindred possibilities of development of concrete

construction along lines of greater economy, it is not likely that the lowest construction costs given in this book will look very low to readers of its next edition.

Cost of Manufacturing Cement.—Bolleau & Lyon give the following cost of manufacturing slag cement:

"The following figures may be relied upon as absolutely accurate. They represent the writer's experience as treasurer and general manager of the Maryland Cement Co. of Baltimore."

Cost for an output of 5,000 bbls. per month:

	Per bbl.
Mill force, labor and supt.....	\$0.160
125 tons coal per mo., at \$2.05.....	0.076
3,000 bu. lime per mo., at \$0.18.....	0.100
900 tons slag per mo., at \$0.50.....	0.090
Repairs, \$100 per mo.....	0.020
Oil and grease, \$40 per mo.....	0.007
Contingencies	0.011
Total	\$0.464
Administration	0.121
Grand total	\$0.585

The same authorities give the following estimate of cost of manufacturing Portland cement in Pennsylvania in 1904.

The figures are based on an output of 1,200 bbls. per day, using 60-ft. kilns, and are the results of actual experience in Pennsylvania.

<i>Labor:</i>	Per bbl.
Quarry	\$0.056
Stone house (2 men each shift).....	0.005
Mill building (6 men each shift).....	0.015
Kiln room (4 men each shift).....	0.015
Engine and boiler room (4 men each shift).....	0.015
Fuel mill (3 men per shift).....	0.010
Yard gang (13 men one shift).....	0.015
Repair gang (12 men one shift).....	0.023
Packing house	0.040
Miscellaneous	0.002
Total labor	\$0.190
<i>Raw Material:</i>	
Coal for quarry and mill.....	\$0.225
Gypsum	0.018
Total raw material.....	\$0.243
<i>Supplies:</i>	
Repair parts	\$0.040
Lubricants	0.020
Miscellaneous supplies	0.030
Total supplies	\$0.090
<i>Plant Charges:</i>	
Interest	\$0.070
Sinking fund	0.050
Depreciation and wear and tear.....	0.050
Total plant charges.....	\$0.170

General Expenses:	
Office force (12 men one shift).....	\$0.020
Administration and selling.....	0.065

Total general expenses.....	\$0.085
Grand total	\$0.778

The above figures multiplied by 1,200 give the daily cost.

There were 4 boilers, each 250 hp., and 3 engines of 500 hp. each. Six kilns were run, two shifts daily.

The fuel for burning clinker was gas slack coal, at \$2.60 per ton, requiring 105 lbs. per bbl. of clinker. Under the boilers and in the dryers 75 lbs. of bituminous coal (at \$3 per ton) per bbl. of cement.

The mill equipment was of the ball and tube type.

A mill can be built for \$50,000 to \$60,000 per kiln, exclusive of land. A 1,200-bbl. plant (6 kilns) need not cost more than \$420,000 including land. From 30 to 100 acres, at \$200 per acre, are commonly used by larger plants than this. Figuring on 11 mos. run, or an annual output of 360,000 bbls., interest at 6% on \$420,000 is \$25,200 per year, or 7 cts. per bbl.

A 60-ft. kiln costs \$2,000, but a 140-ft. kiln can be bought for \$5,000, and will do the duty of two 60-ft. kilns at much less expense; 100-ft. kilns have turned out as much as 475 bbls. per day. The Edison Cement Co. uses 150-ft. kilns.

In a well-equipped mill without countershafting, the raw and clinker mills alone use half the horsepower, and of the repair parts fully 75% are required by them, as well as 50% of the lubricants and 40% of the miscellaneous supplies. One-third the cost of a cement mill is in the crushing and pulverizing departments with their necessary buildings and power.

The stone from the quarry is crushed to 2½ to 3-in. size in a No. 5 or 6 gyratory crusher, but a No. 7½ or 8 is much better.

In the 1,200-bbl. mill, three ball mills and three tube mills on the raw side kept the six 60-ft. kilns going even when 1,310 bbls. were turned out per day. The same number of ball and tube mills on the clinker side, however, only averaged 750 bbls. per day, but under better management this was increased to 900 bbls.

Theory of the Quantity of Cement in Mortar and Concrete.—All sand contains a large percentage of voids. In 1 cu. ft. of loose sand there are 0.2 to 0.5 cu. ft. of voids; that is, 30% to 50% of the sand is voids. In making mortar the cement is mixed with sand, and the flour-like grains of the cement fit in between the grains of the sand, occupying a part or all of the voids in the sand. According to the old theory (as given in Trautwine's Pocket-book and elsewhere), the amount of cement required to make a given mortar is calculated as follows: Suppose the mortar is to be 1 cu. ft. of cement to 2 cu. ft. of sand (a 1 to 2 mortar); and suppose the sand contains 35% voids, then 2 cu. ft. of sand would contain 2×0.35 ; or 0.7 cu. ft. voids. Now, the 1 cu. ft. of cement would fill this 0.7 cu. ft. of voids in the sand and leave an excess of $1 - 0.7$, or 0.3 cu. ft. of cement; hence, the resulting mortar would be 2 cu. ft. of sand + 0.3 cu. ft. of cement (the excess left over after filling the voids in the sand), thus making 2.3 cu. ft.

of mortar from the mixture of 1 cu. ft. of cement with 3 cu. ft. of sand. As above stated, this simple theory was commonly given by all writers (without exception, so far as I know), although many contractors and some engineers must have learned by experience that the theory is incorrect. In 1901, I called public attention to the errors of the theory and published a formula that gives much closer approximations to actual tests.

Since a correct estimate of the number of barrels of cement per cubic yard of mortar or concrete is very important, and since it is not always possible to make actual mixtures before bidding, it seems wise to give space to a discussion of the theory that I have offered.

When loose sand is mixed with water, its volume or bulk is increased, subsequent jarring will decrease its volume, but still leave a net gain of about 10%; that is, 1 cu. ft. of dry sand becomes about 1.1 cu. ft. of damp sand. Not only does this increase in the volume of the sand occur, but, instead of increasing the voids that can be filled with cement, there is an absolute loss in the volume of available voids. This is due to the space occupied by the water necessary to bring the sand to the consistency of mortar; furthermore, there is seldom a perfect mixture of the sand and cement in practice, thus reducing the available voids. It is safe to call this reduction in available voids about 10%.

When loose, dry Portland cement is wetted, it shrinks about 15% in volume, behaving differently from the sand, but it never shrinks back to quite as small a volume as it occupies when packed tightly in a barrel. Since barrels of different brands vary widely in size, the careful engineer or contractor will test any brand he intends using in large quantities, in order to ascertain exactly how much cement paste can be made. He will find a range of from 3.2 cu. ft. to 3.8 cu. ft. per bbl. of Portland cement. Obviously the larger barrel may be cheaper though its price is higher. Specifications often state the number of cubic feet that will be allowed per barrel in mixing the concrete ingredients, so that any rule or formula to be of practical value must contain a factor to allow for the specified size of the barrel, and another factor to allow for the actual number of cubic feet of paste that a barrel will yield—the two being usually quite different.

The deduction of a rational, practical formula for computing the quantity of cement required for a given mixture will now be given, based upon the facts above outlined.

Let p = number of cu. ft. cement paste per bbl., as determined by actual cost.

n = number of cu. ft. of cement per bbl., as specified in the specifications.

s = parts of sand (by volume) to one part of cement, as specified.

g = parts of gravel or broken stone (by volume) to one part of cement, as specified.

v = percentage of voids in the dry sand, as determined by tests

V = percentage of voids in the gravel or stone, as determined by test.

Then, in a mortar of 1 part cement to s parts sand, we have:

ns = cu. ft. of dry sand to 1 bbl. cement.

$ns v$ = cu. ft. of voids in the dry sand.

$0.9 ns v$ = cu. ft. of available voids in the wet sand.

$1.1 ns$ = cu. ft. of wet sand.

$p - 0.9 ns v$ = cu. ft. of cement paste in excess of the voids.

Therefore:

$1.1 ns + (p - 0.9 ns v)$ = cu. ft. of mortar per bbl.

Therefore:

$$N = \frac{27}{1.1 ns + (p - 0.9 ns v)} = \frac{27}{p + ns (1.1 - 0.9 v)}$$

N being the number of barrels of cement per cu. yd. of mortar.

When the mortar is made so lean that there is not enough cement paste to fill the voids in the sand, the formula becomes

$$N = \frac{27}{1.1 ns}$$

A similar line of reasoning will give us a rational formula for determining the quantity of cement in concrete, but there is one point of difference between sand and gravel (or broken stone), namely, that the gravel does not swell materially in volume when mixed with water. However, a certain amount of water is required to wet the surface of the pebbles, and this water reduces the available voids, that is, the voids that can be filled by the mortar. With this in mind, the following deduction is clear, using the nomenclature and symbols above given:

ng = cu. ft. of dry gravel (or stone).

$ng V$ = cu. ft. of voids in dry gravel.

$0.9 ng V$ = cu. ft. of "available voids" in the wet gravel.

$p + ns (1.1 - 0.9 v) - 0.09 ng V$ = excess of mortar over the available voids in the wet gravel.

$ng + p + ns (1.1 - 0.9 v) - 0.9 ng V$ = cu. ft. of concrete from 1 bbl. cement.

$$N = \frac{27}{p + ns (1.1 - 0.9 v) + ng (1 - 0.9 V)}$$

N being the number of barrels of cement required to make 1 cu. yd. of concrete.

This formula is rational and perfectly general. Other experimenters may find it desirable to use constants slightly different from the 1.1 and the 0.9, for fine sands swell more than coarse sands, and hold more water.

The reader must bear in mind that when the voids in the sand

exceed the cement paste, and when the available voids in the gravel (or stone) exceed the mortar, the formula becomes:

$$N = \frac{27}{ng}$$

These formulas give the amounts of cement in mortars and concretes compacted in place. Tables I to IV are based upon the foregoing theory, and will be found to check satisfactorily with actual tests.

TABLE I. BARRELS OF PORTLAND CEMENT PER CUBIC YARD OF MORTAR. (Voids in sand being 35%, and 1 bbl. cement yielding 3.65 cu. ft. of cement paste.)

Proportion of Cement to Sand.		1 to 1	1 to 1½	1 to 2	1 to 2½	1 to 3	1 to 4
		Bbls.	Bbls.	Bbls.	Bbls.	Bbls.	Bbls.
Barrel specified to be	3.6 cu. ft.	4.22	3.49	2.97	2.57	2.28	1.76
"	3.8 "	4.09	3.33	2.81	2.45	2.16	1.62
"	4.0 "	4.00	3.24	2.73	2.36	2.08	1.54
"	4.4 "	3.81	3.07	2.57	2.27	2.00	1.40
Cu. yds. sand per cu. yd. mortar		0.6	0.7	0.8	0.9	1.0	1.0

TABLE II. BARRELS OF PORTLAND CEMENT PER CUBIC YARD OF MORTAR. (Voids in sand being 45%, and 1 bbl. cement yielding 3.4 cu. ft. of cement paste.)

Proportion of Cement to Sand.		1 to 1	1 to 1½	1 to 2	1 to 2½	1 to 3	1 to 4
		Bbls.	Bbls.	Bbls.	Bbls.	Bbls.	Bbls.
Barrel specified to be	3.6 cu. ft.	4.62	3.80	3.25	2.84	2.35	1.76
"	3.8 "	4.32	3.61	3.10	2.72	2.16	1.62
"	4.0 "	4.19	3.46	3.00	2.64	2.06	1.54
"	4.4 "	3.94	3.34	2.90	2.57	1.86	1.40
Cu. yds. sand per cu. yd. mortar		0.6	0.8	0.9	1.0	1.0	1.0

In using these tables remember that the proportion of cement to sand is by volume, and not by weight. If the specifications state that a barrel of cement shall be considered to hold 4 cu. ft., for example, and that the mortar shall be 1 part cement to 2 parts sand, then 1 barrel of cement is mixed with 8 cu. ft. of sand, regardless of what is the actual size of the barrel, and regardless of how much cement paste can be made with a barrel of cement. If the specifications fail to state what the size of a barrel will be, then the contractor is left to guess.

If the specifications call for proportions by weight, assume a Portland barrel to contain 380 lbs. of cement, and test the actual weight of a cubic foot of the sand to be used. Sand varies extremely in weight, due both to the variation in the per cent of voids, and to the variation in the kind of minerals of which the sand is composed. A quartz sand having 35% voids weighs 107 lbs. per cu. ft.; but a quartz sand having 45% voids weighs only 91 lbs. per cu. ft. If the weight of the sand must be guessed at, assume 100 lbs. per cu. ft. If the specifications require a mixture of 1 cement to 2 of sand by weight, we will have 380 lbs. (or 1 bbl.) of cement mixed with 2×380 , or 760 lbs. of sand; and if the sand weighs 90 lbs. per cu. ft., we shall have $760 \div 90$, or 8.44 cu. ft. of sand to

every barrel of cement. In order to use the tables above given, we may specify our own size of barrel; let us say 4 cu. ft.; then $8.44 \div 4$ gives 2.11 parts of sand by volume to 1 part of cement. Without material error we may call this a 1 to 2 mortar, and use the tables, remembering that our barrel is now "specified to be" 4 cu. ft. If we have a brand of cement that yields 3.4 cu. ft. of paste per bbl., and sand having 45% voids, we find that approximately $\frac{2}{3}$ bbls. of cement per cu. yd. of mortar will be required.

It should be evident from the foregoing discussions that no table can be made, and no rule can be formulated that will yield accurate results unless the brand of cement is tested and the percentage of voids in the sand determined. This being so the sensible plan is to use the tables merely as a rough guide, and, where the quantity of cement to be used is very large, to make a few batches of mortar using the available brands of cement and sand in the proportions specified. Ten dollars spent in this way may save a thousand, even on a comparatively small job, by showing what cement and sand to select.

TABLE III. INGREDIENTS IN 1 CUBIC YARD OF CONCRETE.

(Sand voids, 40%; stone voids, 45%; Portland cement barrel yielding 3.65 cu. ft. paste. Barrel specified to be 3.8 cu. ft.)							
Proportions by Volume.	1:2:4	1:2.5	1:2.6	1:2½	1:2½:5	1:2½:6	1:3:4
Bbls. cement per cu. yd.							
concrete	1.46	1.30	1.18	1.13	1.00		1.25
Cu. yds. sand per cu. yd.							
concrete	0.41	0.36	0.33	0.40	0.35		0.53
Cu. yds. stone per cu. yd.							
concrete	0.82	0.90	1.00	0.80	0.84		0.71
Proportions by Volume	1:3:5	1:3:6	1:3:7	1:4:7	1:4:8	1:4:9	
Bbls. cement per cu. yd.							
concrete	1.13	1.05	0.96	0.82	0.77		0.73
Cu. yds. sand per cu. yd.							
concrete	0.46	0.44	0.40	0.46	0.43		0.41
Cu. yds. stone per cu. yd.							
concrete	0.80	0.88	0.93	0.80	0.86		0.92

Note.—This table is to be used where cement is measured packed in the barrel for the ordinary barrel holds 3.8 cu. ft.

It will be seen that the above table can be condensed into the following rule:

Add together the number of parts and divide this sum into ten, the quotient will be approximately the number of barrels of cement per cubic yard.

Thus for a 1:2:5 concrete, the sum of the parts is $1+2+5$, which is 8; then $10 \div 8$ is 1.25 bbls., which is approximately equal to the 1.30 bbls. given in the table. Neither this rule nor this table is applicable if a different size of cement barrel is specified, or if the voids in the sand or stone differ materially from 40% and 45% respectively. There are such innumerable combinations of varying voids, and varying sizes of barrel, that the author does not deem it worth while to give other tables.

TABLE IV. INGREDIENTS IN 1 CUBIC YARD OF CONCRETE.

(Sand voids, 40% ; stone voids, 45% ; Portland cement barrel yielding 3.65 cu. ft. of paste. Barrel specified to be 4.4 cu. ft.)

Proportions by Volume.	1:2:4	1:2:5	1:2:6	1:2½:5	1:2½:6	1:3:4
Bbla. cement per cu. yd. concrete	1.30	1.16	1.00	1.07	0.96	1.08
Cu. yds. sand per cu. yd. concrete	0.42	0.38	0.33	0.44	0.40	0.53
Cu. yds. stone per cu. yd. concrete	0.84	0.95	1.00	0.88	0.95	0.71
Proportions by Volume.	1:3:5	1:3:6	1:3:7	1:4:7	1:4:8	1:4:9
Bbla. cement per cu. yd. concrete ...	0.96	0.90	0.82	0.75	0.68	0.64
Cu. yds. sand per cu. yd. concrete	0.47	0.44	0.40	0.49	0.44	0.42
Cu. yds. stone per cu. yd. concrete	0.78	0.82	0.93	0.86	0.88	0.95

NOTE.—This table is to be used when the cement is measured loose, after dumping it into a box for under such conditions a barrel of cement yields 4.4 cu. ft. of loose cement.

CEMENT PER CUBIC YARD OF MORTAR BY TEST.

According to tests by Sabin, by Fuller (in Taylor and Thompson) and by H. P. Boardman, the following results were obtained:

	Neat.	1:1.	1:2.	1:3.	1:4.	1:5.	1:6.	1:7.	1:8.
Authority.	Bbla.	Bbla.	Bbla.	Bbla.	Bbla.	Bbla.	Bbla.	Bbla.	Bbla.
Sabin	7.40	4.17	2.84	2.06	1.62	1.33	1.14
W. G. Fuller...	8.02	4.58	3.09	2.30	1.80	1.48	1.23	1.11	1.00
H. P. Boardman	7.40	4.50	3.18	2.35

The proportions were by barrels of cement to barrels of sand, and Sabin called a 380-lb. barrel 3.65 cu. ft., whereas Fuller called a 380-lb. barrel 3.80 cu. ft.; and Boardman called a 380 lb. barrel 3.5 cu. ft. Sabin used a sand having 38% voids; Fuller used a sand having 45% voids; and Boardman used a sand having 38% voids. It will be seen that the cement used by Sabin yielded 3.65 cu. ft. of cement paste per bbl. (i. e. $27 \div 7.4$), whereas the (Atlas) cement used by Fuller yielded 3.4 cu. ft. of cement paste per bbl. Sabin found that a barrel of cement measured 4.37 cu. ft. when dumped and measured loose.

Mr. Boardman states a barrel (280 lbs., net) of Lehigh Portland cement yields 3.65 cu. ft. of cement paste; and that a barrel (265 lbs., net) of Louisville natural cement yields 3.0 cu. ft. of cement paste.

Mr. J. J. R. Croes, M. Am. Soc. C. E., states that 1 bbl. of Rosendale cement and 2 bbla. of sand (8 cu. ft.) make 9.7 cu. ft. of mortar, the extreme variations from this average being 7%.

The Size and Weight of Barrels of Cement.—A barrel of Portland cement contains 380 lbs. of cement, and the barrel itself weighs 20 lbs. more. The size of the barrel varies considerably, due to the difference in weight per struck bushel, and to the difference in compressing the cement in the barrel. A light burned Portland cement weighs 100 lbs. per struck bushel; a heavy burned cement weighs 118 to 125 lbs. per struck bushel. The number of cubic feet of packed Portland cement in a barrel ranges from 3 to 3½. English Portland cement barrels contain 3½ to 3¾ cu. ft.

packed. There are usually four bags (cloth sacks) of cement to the barrel, and each bag itself weighs $1\frac{1}{2}$ lbs.

The natural cements are lighter than Portland. The Western cements, such as Louisville, Akron and Utica weigh 265 lbs. per bbl., and the barrel weighs 15 lbs. more. A barrel of Louisville cement = $3\frac{1}{4}$ cu. ft. packed. The Rosendale cements of New York and Pennsylvania weigh 300 lbs. per bbl. and the barrel weighs 20 lbs. more. There are usually three bags of natural cement to the barrel.

When cement is ordered in cloth sacks, there is a charge made of 10 cts. per sack, but on return of the sacks a credit of 8 to 10 cts. per sack is allowed. Cement ordered in wooden barrels costs 10 cts. more per bbl. than in bulk. Cement ordered in paper bags costs 5 cts. more per bbl. than in bulk. Hence it is that nearly all cement used in large quantities is ordered in cloth sacks which are returned.

When a barrel of cement is dumped out and shoveled into a box it measures much more than when packed in the barrel, ordinarily from 20 to 30% more. I have measured a number of barrels of English Portland cement, which is still much used on the Pacific Coast of America, and find that a barrel having a capacity of $3\frac{1}{4}$ cu. ft. between heads will yield 4.5 cu. ft. of cement measured dry and loose in a box. I have found brands of American Portland cement that yield 4.65 cu. ft. when measured loose in a box. The variation is considerable, as is seen in the following table, compiled from data given by Mr. Howard Carson, M. Am. Soc. C. E.:

Brand of Portland cement.	(1) Capacity of bbl. Cu. ft.	(2) Actual contents of packed bbl. Cu. ft.	(3) Volume when dumped loose. Cu. ft.	Increase in bulk.
Giant	3.5	3.25	4.17	25%
Atlas	3.45	3.21	3.75	18%
Saylor's	3.25	3.15	4.05	30%
Alsen (German)	3.22	3.16	4.19	33%
Dyckerhoff (German)	3.12	3.08	4.00	33%

Some engineers require the contractor to measure the sand and stone in the same sized barrel that the cement comes in; then 1 part of sand or stone usually means $3\frac{1}{4}$ cu. ft. Other engineers permit both heads of the barrel to be knocked out, for convenience in measuring the sand and stone; then a barrel means about $3\frac{1}{4}$ cu. ft. Still other engineers permit the contractor to measure his cement in a box loose; then a barrel usually means from 4 to 4.5 cu. ft. Since most of the cement now used is shipped in bags and since four bags of Portland cement make a barrel, it is the custom among most engineers to call a bag 1 cu. ft., even though it may yield a little more cement. Still other engineers prefer to specify that a Portland barrel shall be called 3.8 cu. ft., which is equivalent to 100 lbs. of cement per cu. ft.

It is desirable that engineers and architects adopt some uniform practice in this matter, for now a contractor is often unable to estimate the quantity of cement required for any specified mixture because the size of the barrel is not specified.

There have been advocates of proportioning parts by weight, but, aside from the fact that it is seldom convenient to weigh the ingredients of every batch, there is no gain in such a departure from long-standing precedent. Sand and gravel and stone are by no means constant in specific gravity, as advocates of weighing seem to suppose.

Effect of Moisture on Voids in Sand.—Few engineers and fewer contractors realize how greatly the volume of sand is affected by the presence of varying percentages of moisture in the sand. A dry, loose sand that has 45% voids if mixed with 5% (by weight) of water will swell (unless tamped) to such an extent that its voids may be 57%. The same sand if saturated with more water until it becomes a thin paste, may show only 37½% voids after the sand has settled. The following tests by Feret show the effect that water has upon sand:

Two kinds of sand were used, a very fine sand and a coarse sand. They were measured in a box that held 2 cu. ft. and was 8 ins. deep, the sand being shoveled into the box, but not tamped or shaken. After measuring and weighing the dry sand, 0.5% (by weight) of water was added, the sand was mixed and shoveled into the box again and weighed. This was repeated with varying percentages of water, up to 10%, with the following results:

Per cent of water in sand.	0%	0.5%	1%	2%	3%	5%	10%
	Lbs.	Lbs.	Lbs.	Lbs.	Lbs.	Lbs.	Lbs.
Weight per cu. yd. of fine sand and water....	3,457	2,206	2,085	2,044	2,037	2,035	2,133
Weight per cu. yd. of coarse sand and water.	2,551	2,466	2,380	2,122	2,058	2,070	2,200

It will be noted that the weight of mixed sand and water is given; but, to ascertain the exact weight of dry sand in the mixture, divide the weight given in the table by 100% plus the given tabular per cent; thus, the weight of dry fine sand mixed with 5% of water is $2,035 \div 1.05 = 1,938$ lbs. per cu. yd. It will also be noted that when the water exceeds 3 to 5%, the weight of the mixture increases, showing that a larger percentage of water compacts the sand. The voids in the dry fine sand were 45%, and in the sand with 5% moisture they were 56.7%.

It is well known that pouring water onto loose, dry sand compacts it. By mixing fine sand and water to a thin paste, pouring it into a pail and allowing it to settle, it was found that the sand occupied 11% less space than when measured dry in a box. The voids in fine sand, having a specific gravity of 2.65, were determined by measurements in a quart measure, and found to be as follows:

	Voids
Sand, not packed	44½%
Sand, shaken to refusal.....	35%
Sand, saturated with water.....	37½%

Mr. H. P. Boardman made some experiments with Chicago sand having 34 to 40% voids when dry, by adding water to the sand. The results were as follows:

Water added, % by weight....	$\frac{1}{2}$	$\frac{4}{5}$	$\frac{6}{5}$	$\frac{8}{5}$	$\frac{10}{5}$
Resulting increase in volume..	17.6	22	19.5	16.6	15.6

However, a very moderate amount of shaking would reduce this increase in volume by $\frac{1}{2}$ to $\frac{1}{3}$.

Effect of Size of Sand Grains on Voids.—If in any given volume of sand all the grains were of the same shape and of uniform size, the percentage of voids would be the same regardless of the size of the grains. This is equivalent to saying that the finest birdshot has the same percentage of voids as the coarsest buckshot. Natural sand grains, unless they have been sorted by screening, are apt to vary greatly in size, large and small being intermixed. It is this that causes such wide discrepancies in published data as to the percentage of voids in dry bank sands. We may divide sand into three sizes, for convenience. The largest size (L) being sand that will pass a sieve of 5 meshes per lineal inch, but will not pass a sieve of 15 meshes per lineal inch; the medium size (M) being sand that will pass a 15-mesh sieve, but will not pass a sieve of 50 meshes per lineal inch; and the fine size (F) being sand that will pass a 50-mesh sieve. If we mix varying proportions of the large, medium and fine (L, M and F), we find that we get the densest mixture, with the least voids, when we have an L6, M0, F4 mixture, that is, 6 parts large size, no parts medium, and 4 parts fine size. With a dry sand whose grains have a specific gravity of 2.65, if we weigh a cubic yard of either the fine, or the medium, or the large size, we find a weight of 2,190 lbs. per cu. yd., which is equivalent to 51% voids. If we mix the three different sizes in varying proportions, we find, as above stated, that an L6, M0, F4 mixture is densest, and it weighs 2,840 lbs. per cu. yd. shoveled into a box dry. This is equivalent to 36% voids. We can get a denser mixture, with a lower percentage of voids, if we mix about equal parts of sand and clean gravel. It will be noted that the common statement that the densest mixture is obtained by a mixture of gradually increasing sizes of grains is erroneous. There must be enough difference in the sizes of grains to provide voids so large that the smaller grains will enter them and not wedge the larger grains apart.

The shape of the grains has a very pronounced effect upon the percentage of voids, rounded grains having less voids than angular grains. Using sand having a granulometric composition of L6, M3, F1, measured in a quart measure, the following results were obtained by Forst:

	Voids.	
	Unshaken.	Shaken.
Natural sand, rounded grains.....	36.9%	35.6%
Crushed quartzite angular grains.....	42.1	37.4
Crushed shells, flat grains.....	44.2	31.8
Residue of quartzite, flat grains.....	47.5	34.6

The measure was shaken until no further settlement could be produced.

Mr. William B. Fuller made the following tests: A dry sand, having 34% voids shrank 2.8% in volume upon thorough tamping.

until it had 27% voids. The same sand moistened with 6% water, and loose, had 44% voids, which was reduced to 31% by ramming. The same sand saturated with water had 38% voids, and by thorough ramming its volume was reduced 8½%, until the sand had only 26½% voids.

1	0.52	.53	1.04	0.58	.49	.98	0.56	.47	.94

Notes.—Water required proportional to amount of cement used. Costs less than hand mixing. Costs estimated, per cu. yd., \$1.20; per cu. yd., \$1.62. Average in place. Safe strength, ultimate, 6. Concrete is directly proportional to strength tests of product) 20% better than delivered, per bbl. (net), \$1.75; sand, delivered, \$1.90; gravel, delivered, per cu. yd., \$1.15; labor, per cu. yd. in place. Hand mixing, \$1.50 per cu. on beam, ultimate, 4.5; working stress in concrete.

Ratio of strength of concrete based on 1:2½:5 mix.	Av. volume of a batch in place using 1 bbl. cem. (3.8 cu. ft.)			Cost per cu. ft. of concrete in place.			Ultimate compressive strength stone concrete 6-in. cubes 1 month old in lb. per sq. in.		
	Stone.	Broken Gravel.	Clean Gravel.	Stone.	Broken Gravel.	Clean Gravel.	Stone.	Broken Gravel.	Clean Gravel.
2.41	6.8 cu. ft.	\$0.37	\$0.34	5.540					
1.73	9.7 cu. ft.	0.314	0.274	4.000					
1.39	12.0 cu. ft.	0.283	0.237	3.200					
1.17	16.5 cu. ft.	0.264	0.214	2.700					
1.00	20.0 cu. ft.	0.246	0.195	2.300					
.87	24.0 cu. ft.	0.230	0.179	2.000					
.70	31.0 cu. ft.	0.210	0.160	1.625					
.61	38.0 cu. ft.	0.200	0.149	1.400					
.54	45.0 cu. ft.	0.192	0.141	1.250					

similar scope is given here (Table VII). This table has been compiled by Mr. H. J. Fixmer, Assistant Engineer, Board of Local Improvements, Chicago, Ill., from various and it is believed trustworthy sources. The cost column, while necessarily based on given constants, shows relative costs of different mixtures which are fairly true for all cases. These costs, in connection with the ratio of strength figures, show almost at a glance the economy of the selected mixtures.

Table VIII is used in designing slabs and girders. Attention is called to the fact that the value A is used and that the value $d-A$ is the selected thickness of the fireproofing only. In other words the depth of the beam is the value A plus the thickness required for fireproofing. The value $f_c=500$ lbs.—is practically the universal building code allowance. The value f_s of course varies with the percentage of steel used. A little study of the table shows the advantage of using not less than 1½% of steel for reinforcing.

For purposes of comparison the following data as to brickwork are useful:

	Crushing strength lbs. per sq. in.	Cost per cu. ft.
First-class brickwork in cement mortar.....	834	\$0.44
Good brick in cement mortar.....	486	0.35
Ordinary brick in lime mortar.....	347	0.26
1,000 brick = 40 cu. ft. when laid.		

Percentage of Water Required in Mortar.—A good rule by which to determine the percentage of water by weight for any given mixture of mortar is as follows: Multiply the parts of sand by 8, add 24 to the product and divide the total by the sum of the parts of sand and cement.

Example: Required percentage of water for a mortar of 1 cement to 3 sand:

SOLUTION.

$$\begin{array}{rcl}
 1 \text{ cement} & & = 24\% \\
 3 \text{ sand} \times 8\% & = & 24\% \\
 \hline
 4 \text{ parts at } 12\% & = & 48\%
 \end{array}$$

Hence the water should be 12% of the combined weight of the cement and sand. For a 1:1 mortar, the rule gives 16% water. For 1:2 mortar the rule gives 13½% water. For a 1:3 mortar the rule gives 10.8% water. Incidentally, it may be added, the percentages of water obtained by this rule give a mortar that has the greatest adhesion to steel rods (see Falk's "Cements, Mortars and Concretes," page 61).

About 23 gals of water are required per cu. yd. of 1:3:5 concrete.

Estimating the Cost of Steel in Reinforced Concrete.—In reinforced concrete the amount of steel is usually expressed in percentages of the volume of concrete. Thus 1% of steel means that one one-hundredth part of the volume of reinforced concrete is steel. In a cubic yard of reinforced concrete there is 1% of 27 cu. ft., or 0.27 cu. ft. of steel, if the reinforcement is 1%. A cubic foot of steel weighs 490 lbs., but for all practical purposes we can call it 500 lbs.

TABLE VIII.—REINFORCED CONCRETE BEAM AND SLAB TABLE.

(Table based on a 1:2½:5 mix concrete (1 month old) wherein $\frac{E_s}{E_c} = \frac{30,000,000}{2,500,000} = 12$, $f_c = 500$ lbs. per sq. in. $f_s = \frac{1}{2}$ (or $\frac{1}{4}$) elastic limit of steel in lbs. per sq. in.)

sq. in.	$f_s = \frac{1}{2}$ (or $\frac{1}{4}$)	Unit Work'g Stress in Concrete.	$f_c =$ Stress in Steel.	Dimensions in Fig. 1.			$M_o =$ Resisting Moment in inch lbs.	$A_s =$ Area of Steel in sq. in.	$P =$ Per cent of Steel.	Reinforcing.		
				Y1. Y2. Y3.						Diam. of Bars.	Area in sq. in. Square.	Round.
				Y1.	Y2.	Y3.						
500	20,000	0.23	0.77	0.93	55.8	0.030bh	30/100%	¼ in.	0.17	.012

500	12,000	0.33	0.67	0.89	73.68bh²	.0062bh	62/100%	¼ in.	0.25	.196		
500	10,000	0.37	0.63	0.87	80.05bh²	.0092bh	92/100%	¼ in.	0.39	.307		
500	8,000	0.43	0.57	0.85	91.12bh²	.0134bh	134/100%	¼ in.	0.60	.443		
500	6,000	0.50	0.50	0.83	103.6 bh²	.0208bh	208/100%	¾ in.	.766	.600		
500	4,000	0.60	0.40	0.80	120.0 bh²	.0375bh	375/100%	1 in.	1.00	.786		
								1 ¼ in.	1.66	1.23		
								1 ½ in.	2.29	1.766		

Notes.— $M_o =$ Resisting Moment, $= K A_s f_s$. $d - h =$ (for fireproofing) $= \frac{1}{4}$ in. to $2\frac{1}{2}$ in. $B. M. =$ Bending Moment. For Uniform Load $= \frac{W l^2}{8}$. $W =$ Total Weight incl. w't of Concrete. $l =$ span in in. Working

er sq. in. Working Stress, Adhesion, $= 75$ lbs. per sq. in. 1 24/100% Steel) or greater per cent gives most economical reinf.
 2½ times the weight of Concrete. Steel at 2½ cts. per lb. costs (av.) 50 times
 1 area of bars in sq. ins. times 3.4 gives the weight of bars in lbs. per lineal
 ranges from 1/4 ct. to 1/2 ct. per lb. Use $f_c = 500$ lbs. and 1:2½:5 mix for
 mix when using factor of safety greater than 4.

Hence reinforced concrete containing 1% of steel has $0.27 \times 500 = 135$ lbs. of steel per cu. yd.

Per cent. of Steel.	Lbs. of Steel Per Cu. Ft.	Lbs. of Steel Per Cu. Yd.
0.20	1.00	27.0
0.20	1.25	33.8
0.30	1.50	40.5
0.35	1.75	47.3
0.40	2.00	54.0
0.45	2.25	60.8
0.50	2.50	67.5
0.55	2.75	74.3
0.60	3.00	81.0
0.65	3.25	87.8
0.70	3.50	94.5
0.75	3.75	101.3
0.80	4.00	108.0
0.85	4.25	114.8
0.90	4.50	121.5
0.95	4.75	128.3
1.00	5.00	135.0

Knowing the price of steel for reinforcing, it is a simple matter of multiplication to estimate the cost of the steel for any percentage of reinforcement. For example it is desired to know the cost of steel for a concrete sewer reinforced with twisted bars $\frac{3}{8}$ -in. square, the steel amounting to 0.30%. According to the table there would be 40.5 lbs. of steel per cu. yd. in concrete reinforced with 0.30% of steel. The following table of prices is given in a catalog of Ransome's in 1906.

PRICE OF RANSOME TWISTED STEEL BARS.

Add the prices given below to the prevailing prices for plain steel bars f. o. b. Pittsburgh.

	Per 100 lbs.
Larger than $\frac{3}{8}$ inch square add.....	0.30
Larger than $\frac{11}{16}$ inch square add.....	0.375
Larger than $\frac{1}{2}$ inch square add.....	0.375
Larger than $\frac{9}{16}$ inch square add.....	0.425
Larger than $\frac{1}{2}$ inch square add.....	0.425
Larger than $\frac{7}{16}$ inch square add.....	0.65
Larger than $\frac{3}{4}$ inch square add.....	0.70
Larger than $\frac{5}{16}$ inch square add.....	0.75
Larger than $\frac{1}{2}$ inch square add.....	0.80
Larger than $\frac{1}{2} \times 1$ inch add.....	0.425
Larger than $\frac{1}{2} \times \frac{1}{2}$ inch add.....	1.20

The above figures are for carload lots. For quantities less than carload lots, add \$0.05 per 100 lbs. For quantities less, between 1,000 lbs. and 2,000 lbs., add \$0.10 per 100 lbs.

For quantities less than 1,000 lbs., add \$0.30 per 100 lbs.

If the present price of plain steel bars is \$1.50 per 100 lbs., f. o. b. Pittsburgh, then the price of $\frac{3}{8}$ -in. Ransome twisted steel bars is $\$1.50 + \0.70 , or \$2.20 per 100 lbs., or 2.2 cts. per lb. f. o. b. Pittsburgh. Let us assume that the freight and haulage brings the price up to 2 $\frac{1}{2}$ cts. per lb., delivered on the job. The labor cost of bending and placing steel in reinforced concrete sewers averages about $\frac{1}{2}$ ct. per lb. Hence the total cost of the steel in place is 3 cts. per

It is in this particular case. Since there are 40½ lbs. of steel per cu. yd. of concrete containing 0.30% steel, we have a total cost of $40.5 \times 3 \text{ cts} = \1.22 per cu. yd. for the steel.

In like manner all similar problems may be solved. To facilitate rapid estimates, it is a good plan to keep records of all reinforced concrete structures in such form as to show the percentage of steel used. In doing this, however, be careful to separate the foundations which are not reinforced from the superstructure which is reinforced. A reinforced concrete arch bridge usually rests on abutments which are not reinforced. Do not lump together all the concrete in making an estimate, but separate the arch from the abutments. Frequently engineers have failed to separate the yardage of foundation from the yardage of superstructure of reinforced concrete bridges, yet without such a separation accurate cost estimates are impossible.

Cost of Sand.—The cost of sand may be estimated by adding together the cost of loading in the pit, the cost of hauling in wagons, the cost of freight and rehandling if necessary and the cost of washing. On page 553 are given data on the cost of shoveling sand into wagons. The cost of wagon hauling is given on page 125. Freight rates can always be secured, and it is usually safe to estimate the weight on a basis of 2,700 lbs. per cu. yd., provided the sand has not been rained upon after loading in the car. The cost of screening sand by hand is the cost of shoveling it up against an inclined screen; but if a large amount of gravel must be screened to get a small amount of sand, care must be taken to make tests in the pit to ascertain how many cubic feet of gravel and sand must be shoveled to secure one cubic foot of sand. In some places sand must be dredged or pumped with a sand pump from the bottom of a river or lake. In other places sand must be made by crushing stone and running the small crushed product through rolls. At Coudersport, Pa., a small plant for making artificial sand from stone has been in operation for many years.

Stone was crushed and passed through rolls in order to make a sand for the mortar used in the Lanchenses Dam, Germany. A jaw crusher, driven by a 15-hp. engine, crushed 65 cu. yds. of stone (graywacke) per 10-hr. day. All pieces from 0.18 to 1.6 in. diameter were passed through rolls. The rolls were 14½ in. long and 34 in. diameter, and made 33 revolutions per minute, requiring 12 to 15 hp. A pair of these rolls produced 20 cu. yds. of sand per 10-hr. day. The rolls had chilled bands which, when worn, were ground true with an emery wheel without removing the rolls.

Where a large amount of concrete is to be made, a contractor can seldom afford to guess at the source of his sand supply. I have known several instances where long hauls over poor roads have made the sand more expensive than the stone per cubic yard of concrete. Each job should be estimated in detail, using the data given elsewhere in this book.

A very common price for sand in cities is \$1 per cu. yd., delivered at the work. Sand is often sold by the load, instead of by the cubic

yard. It is wise to have a written agreement defining the size of a load.

Cost of Washing Sand in a Tank Washer.—Mr. W. H. Roper gives the following data on the cost of washing sand for U. S. Lock No. 3, at Springdale, Pa. The sand dredged from the river contained much fine coal and silt which was removed by the washer, which consisted of a circular tank, 9 ft. diam. x 7 ft. high, provided with a sloping false bottom perforated with 1-in. holes, through which water was forced. A $7\frac{1}{2} \times 5 \times 6$ -in. pump with a 3-in. discharge pipe was used to force the water into the tank. The paddles for keeping the sand in suspension were rotated by a 7-hp. engine. A charge of 14 cu. yds. of sand was washed in from 1 to 2 hrs., at a cost of 7 cts. per cu. yd. This device was designed by Capt. W. R. Graham, who is said to have applied for a patent. It is doubtful whether any patentable combination exists in the device. See Gillette and Hill's "Concrete Construction" for the design of this washer, and also for the design of the one described in the next paragraph.

Mr. F. H. Stephenson gives the following data relating to a sand washer designed by Mr. Allen Hasen, which consisted of a wooden box 10 ft. long, $2\frac{1}{2}$ ft. wide and $2\frac{1}{2}$ ft. deep; a 6-in. pipe, provided with a gate, or valve, enters at one end, and connects with three 3-in. pipes capped at the ends. In the bottoms of these 3-in. pipes are $\frac{1}{2}$ -in. holes, spaced 6 ins. apart, through which water discharges under pressure into the box. Sand is shoveled into the box at one end, and the upward currents of water raise the fine and dirty particles until they escape through the waste troughs. When the box becomes filled with sand a sliding door is raised at the end, and the clean sand flows out through a 3-in. hole in the box. The operation is continuous, so long as sand is fed into the washer. By manipulating the door the sand can be made to flow out with a very small percentage of water. Sand containing 7% of dirt was thus washed so that it contained only 0.6% dirt. In 10 hrs. the washer handled 200 cu. yds. of sand.

If sand is handled to and from the washers by shovels the cost of shoveling is the largest item of expense, and this can be easily estimated. If the sand is dumped into bins which feed into the washer by gravity, and is finally delivered by gravity to buckets or cars, the cost of washing is mainly the cost of pumping, plus the interest and depreciation of plant. The amount of water required per cubic yard has been given above, so that a close estimate of cost can readily be made for any given condition.

Other data as to methods and costs of washing sand and gravel will be found in "Concrete Construction—Methods and Cost" by Gillette and Hill.

Cost of Washing Sand With a Hose.—Where the quantity of sand to be washed is not very large, the simplest method is to use water from a hose. Build a tank 3 ft. wide and 15 ft. long, the bottom having a slope of about 3 ins. in the 15 ft. The sides should be about 3 ins. high at the lower end, rising gradually to 3 ft., the

height of the upper end. The lower end of this tank should be closed with a board gate about 8 ins. high, sliding in guides so that it can be removed. Dump about 3 cu. yds. of the dirty sand at the upper end of the platform and play a stream of water upon it from a $\frac{1}{2}$ -in. nozzle, the man standing on the outside of the lower end of the platform. The water and sand flow down the platform and the dirt passes off with the overflow water over the gate. In about an hour the batch of sand will be washed. By building a pair of platforms the washing can proceed continuously, and one man can wash 20 cu. yds. a day, at a cost of 5 cts. per cu. yd. for his labor. To this must be added the cost of shoveling up the sand again, say, 10 cts. per cu. yd., and any extra hauling due to the location of the washer. If the water is pumped, about 10 cts. more per cu. yd. will be spent for coal and wages, making a total of 25 cts. per cu. yd.

Washing With Sand Ejectors.—Where very large quantities of sand are to be washed more expensive apparatus than above described may be used. In Gillette and Hill's "Concrete Construction" will be found detail drawings of what are termed "sand ejectors," consisting of a row of conical hoppers now used extensively for washing filter sand. From the bottom of each hopper the sand and water are forced to the top of the next hopper by a stream of water passing through an ejector. The dirty water overflows at the top of each hopper, and finally clean sand is discharged into receiving bins or buckets. One man can readily attend to feeding the sand into the first hopper and another man will handle the discharge. It requires about 2,000 gals. of water per cu. yd. of sand washed, so that with an output of 35 cu. yds. of sand in 10 hrs., the amount of water to be pumped is 108,000 gals. A gasoline pump may be used.

With such an output the cost would be about as follows:

	Per Day.	Per Cu. Yd.
2 laborers at \$2.....	\$4.00	\$0.111
1 man on pump.....	3.00	0.083
Fuel, etc., for 5 hp. pump.....	1.00	0.028
Total	\$8.00	\$0.222

The cost of pumping can be greatly reduced where a larger yardage is to be washed daily.

For other data on sand washing with ejectors see the part of the section on Waterworks devoted to sand filtering.

Cost of Washing Gravel.—In the Railway Section will be found data on the cost of washing gravel for railway ballast.

Cost of Transporting in Push Carts.—For hauling concrete over comparatively level runways, two-wheel push carts, or concrete buggies, are far more economic than wheelbarrows. A cart having a capacity of 6 cu. ft., and holding about 0.2 cu. yd. of concrete, is pushed by one man. With wages at 15 cts. per hr., and man traveling 200 ft. per min., the cost would be $1\frac{1}{4}$ cts. per cu. yd. per 100 ft. of distance from mixing board to point of dumping the con-

crete. Two lines of plank should be laid for the wheels to travel on.

Cost of Making Concrete by Hand.—The cost of making concrete by hand may be divided into the following items:

- (1) Loading the barrows, buckets, carts or cars used to transport the materials (stone, sand and cement) to the mixing board.
- (2) Transporting and dumping the materials.
- (3) Mixing the materials by turning with shovels or hoes.
- (4) Loading the concrete with shovels into barrows, buckets, carts or cars.
- (5) Transporting the concrete to place.
- (6) Dumping and spreading.
- (7) Ramming.
- (8) Forms, runways, cement house, bins, etc.
- (9) Finishing the surface of the concrete.
- (10) Superintendence and general expenses.

Unloading the Materials From Cars.—The stone and sand will ordinarily be delivered by wagons or cars and dumped into stock piles as near the proposed work as possible, without being in the way after construction begins. The contractor should use forethought not only in planning the location of his stock piles, but also in providing a large enough storage capacity to tide over irregularities in the delivery of materials, especially where materials come by rail from a distance. It is usually a short-sighted policy to attempt to unload direct from the railway cars onto the mixing board, without providing a stock pile; for the foreman will be spending most of his time trying to get the railroad to deliver materials promptly. By all means provide stock piles, unless there is some good reason to the contrary.

Sand can be dumped directly on the ground, but broken stone (unless it is very small, $\frac{1}{4}$ -in. or less in size) should always be dumped upon a plank floor, well made. Such a floor should consist of 2-in. plank laid on 4 x 6-in. stringers, firmly bedded in the ground and spaced about 3 ft. apart. Never lay a lot of loose plank directly upon the ground, without stringers, for they are sure to settle unevenly under the load, and thus make it difficult to shovel up the stone. The object of the plank is to provide an even surface along which a square pointed shovel can be pushed in loading barrows, carts, etc. I find that a man can load 18 or 20 cu. yds. of broken stone into wheelbarrows in 10 hrs., if he is shoveling off a well-laid plank platform, but he will not average more than 12 or 14 cu. yds. a day shoveled from a pile without a plank flooring. The reason is that a shovel can be shoved with difficulty into a mass of broken stone (2-in. size), but can readily be shoved along a plank floor. Incidentally I may add that broken stone delivered in hopper-bottom cars can be shoveled with difficulty as compared with shoveling in flat-bottom cars; the ratio being about 14 cu. yds. per man per day from hopper-bottom cars as compared with 20 cu. yds. from flat cars. On the other hand, the hopper-bottom coal car

should always be chosen where it can be dumped through a trestle. If the amount of work to be done will justify the expense a trestle may be built. Often, however, there is a railroad embankment which can be dug away for a short distance and stringers placed to support the track. Then the cars can be dumped into the hole thus made, and the material shoveled out and down the slope.

Many foremen for railway companies waste hundreds of dollars by shoveling the materials from freight cars out upon the earth—often upon the side of an embankment where shoveling is very difficult. In many cases it would have paid well to have unloaded the cars by the aid of a stiff-leg derrick and iron buckets or skips loaded by the shovelers in the cars; these skips being dumped upon a well-made platform. In other cases chutes lined with sheet iron would have served to deliver the stone upon a plank flooring at the foot of the embankment, just as coal is delivered into a cellar. Damp sand will not slide down a chute on a slope of $1\frac{1}{2}$ to 1, but coarse broken stone, if given a start when cast, with the shovel, will slide on an iron-shod slope of 3 or 4 to 1.

If the material is delivered in wagons it seldom is necessary to have large stock piles provided the wagons come direct from the sand pit and the quarry.

Cost of Loading the Materials.—A man who is a willing worker can readily load 20 cu. yds. of sand into a barrow or cart in 10 hrs., but under poor foremen, or when laborers are scarce, it is not safe to count upon more than 15 cu. yds. a day, or, say, 10 cts. per cu. yd. for loading. Practically the same figures hold true of broken stone shoveled off a good plank floor; but, if the stone is shoveled off the ground, estimate 15 cu. yds. a day under good management, or 13 cu. yds. a day under poor management. Since in a cubic yard of concrete there are ordinarily about 1 cu. yd. of broken stone and about 0.4 cu. yd. of sand, the cost of loading the materials into wheelbarrows and carts is as follows, wages being 15 cts. per hour:

1 cu. yd. stone loaded for 11 cts.
0.4 cu. yd. sand loaded for 4 cts.

1 cu. yd. concrete loaded for 15 cts.

The cement can be loaded with more ease than the other materials, whether it is in barrels or in bags, and the cost of loading it into barrows or carts will be not over 2 cts. per cu. yd. of concrete, thus making a total of 17 cts. per cu. yd. for loading the concrete materials into barrows or carts.

Cost of Transporting the Materials.—The most common way of transporting the materials from stock piles to the mixing board is in wheelbarrows over plank runways. A wheelbarrow is usually loaded with 2 sacks of Portland cement (200 lbs.), or with 2 cu. ft. of stone or of sand, if a steep rise must be made to reach the mixing platform; but, if the run is level, 300 lbs. of cement, or 3 cu. ft. of sand or stone is a common wheelbarrow load. A man wheeling a barrow travels at the rate of about 200 ft. per minute, going and coming, and loses $\frac{1}{2}$ minute each trip dumping the load, fixing run

planks, etc. An active man will do 20 or 25% more work than this, while a very lazy man may do 20% less. With wages at 15 cts. per hour, the cost of wheeling the materials for 1 cu. yd. of concrete may be obtained by the following rule:

To a fixed cost of 4 cts. (for lost time) add 1 ct. for every 20 ft. of distance from stock pile to mixing board if there is a steep rise in the runway, but if the runway is level add 1 ct. for every 30 ft. distance of haul. Since loading the barrows costs 17 cts. per cu. yd. the total fixed cost is $4 + 17$ cts. or 21 cts. per cu. yd., to which is added 1 ct. for every 20 or 30 ft. of haul, according to the character of the runway.

I have frequently seen small stock piles located as close as possible to mixing boards, so that wheelbarrows were not used, the materials being carried in shovels direct to the mixing boards. On work of any considerable size this is a very foolish plan, as we can readily see. It takes from 100 to 150 shovelfuls of stone to make 1 cu. yd. It therefore costs at the rate of 50 cts. per cu. yd. to carry it 100 ft. and return empty handed, for in walking short distances the men travel very slowly—about 150 ft. per minute. From this it appears that it costs more to walk even half a dozen paces with stone carried in shovels than to wheel it in barrows. Of course, by using large coal scoops the cost of carrying material in shovels could be reduced to one-half or one-third the cost with ordinary shovels; but scoops are never used in mixing concrete.

Another mistake that is very commonly made by foremen is to provide no plank runways from the stock pile to the mixing board, but instead to run the wheelbarrows over the ground. This is bad enough even in dry weather over a very hard packed earth path, but after a rain or on a soft pathway it means a great loss of efficiency. Had I not seen this error committed repeatedly, I should not mention it, for it would seem that no foreman could be so shortsighted as not to provide a few planks for runways.

Where the runway must rise to the mixing board, give it a slope or grade seldom steeper than 1 in 3, and if possible flatter. Make a runway on a trestle at least 18 ins. wide, so that men will be in no danger of falling. See to it, also that the planks are so well supported that they do not spring down when walked over, for a springy plank makes hard wheeling. If the planks are so long between the "horres" or "bents" used to support them, that they spring badly, it is usually a simple matter to nail a cleat across the underside of the planks and stand an upright strut underneath to support and stiffen the plank.

Materials may be hauled in one-horse dump-carts for all distances more than 50 ft. (from stock pile to mixing board) at a cost less than for wheelbarrow hauling. A cart should be loaded in 4 mins. and dumped in about 1 min., making 5 mins. lost time each round trip. It should travel at a speed of not less than 200 ft. per min., although it is not unusual to see variations of 15 or 20%, one way or another, from this average, depending upon the management of the work. A one-horse cart will readily carry enough stone and

and to make $\frac{1}{2}$ cu. yd. of concrete, if the roads are fairly hard and level; and a horse can pull this load up a 10% (rise of 1 ft. in 10 ft.) planked roadway provided with cleats to give a foothold. If a horse, cart and driver can be hired for 20 cts. per hour, the cost of hauling the materials for 1 cu. yd. of concrete is given by the following rule:

To a fixed cost of 5 cts. (for lost time at both ends of haul) add 1 ct. for every 100 ft. of distance from stock pile to mixing board. Where carts are used it is possible to locate the stock piles several hundred feet from the mixing boards without adding materially to the cost of the concrete. It is well, however, to have the stock piles in sight of the foreman at the mixing board, so as to insure promptness of delivery.

Cost of Mixing the Materials.—This element of cost depends upon the number of times that the materials are turned over with shovels. I have seen street paving work where the inspection was so lax that the contractor was required to turn over the mass of sand, cement and stone only three times before shoveling it into place. On the other hand, the contractor is rarely required to turn over the cement and sand more than three times dry and three times wet to make the mortar, and then turn over the mortar and stone three times. A willing workman, under a good foreman, will turn over mortar at the rate of 20 cu. yds. in 10 hrs., lifting each shovelful and casting it into a pile. This means a cost of 5 cts. per cu. yd. of mortar for each turn; but as there is seldom more than 0.4 cu. yd. of mortar per cu. yd. of concrete, we have a cost of 2 cts. per cu. yd. of concrete for each turn that is given to the mortar. So if the mortar is given 6 turns before adding the stone, we have 2 cts. \times 6 which is 12 cts. per cu. yd. of concrete for mixing the mortar. Then if the mortar and stone are turned three times we have 5 cts. \times 3, or 15 cts. more for mixing, thus making a total of 27 cts. per cu. yd. for mixing the concrete, wages being 15 cts. per hr.

I recall seeing one specification that called for 6 turns of the mortar dry and 3 turns wet. Under such a specification the cost of mixing the mortar would be 50% more than I have assumed in the example just given. Specifications for hand mixing should always state the number of turns that will be required, but frequently they do not, thus leaving the contractor to guess at the probable requirements of the inspector. In such a case it is a good plan to use hoes instead of shovels for mixing the mortar, because in this way a good mortar can be mixed with much greater rapidity than when an inspector insists on 6 to 9 turns with shovels, as frequently happens when specifications are ambiguous.

As above stated, it often happens that on city pavement work, two turns of the mortar, followed by two turns of the mortar and stone, are considered sufficient. In such a case the cost of mixing the mortar is 2 cts. \times 2, or 4 cts. per cu. yd. of concrete; to which is added 5 cts. \times 2, or 10 cts., for mixing the mortar and stone, making in all 14 cts. per cu. yd. of concrete. When concrete is mixed very wet, or sloppy, this amount of mixing appears to give good results.

Where a given number of turns of concrete is specified, disputes often occur between inspectors and foremen as to whether shoveling into wheelbarrows constitutes a "turn" or not, and whether any subsequent shoveling in getting the concrete to its final resting place constitutes a "turn." It seems but fair to count each handling with the shovel as a turn, no matter when or where it occurs, but inspectors will not always look upon it in that light.

The foregoing costs of mixing apply to work done by diligent men; but easy-going men will make the cost 25 to 50% greater. I have seen this latter class of men most frequently on day labor work for cities, railways and other companies and corporations whose foremen have little or no incentive to secure a fair day's work from the men.

Cost of Loading and Hauling Concrete.—The cost of loading concrete, after it is mixed, is less than the cost of loading the materials separately before mixing, because while the weight is greater (due to the added water), the bulk or volume of the concrete is much less than the volume of the ingredients before mixing. Moreover a smooth mixing board, and the presence of the foreman, secures more rapid work. In shoveling any material a large part of the work consists in forcing the shovel into, or under, the mass to be lifted. With wages at 15 cts. per hour, the cost of loading concrete into barrows or buckets should not exceed 12 cts. per cu. yd. The cost of wheeling it after loading is practically the same as for wheeling the dry ingredients, as given by the rule on page 272. The cost per cubic yard of loading and wheeling is therefore given by this rule: To a fixed cost of 16 cts. (for loading and lost time) add 1 ct. for every 20 ft. of level haul.

If the concrete must be elevated, a gallows frame, or a mast with a pulley block at the top, a team of horses and a rope for hoisting the skip load of concrete, can often be used to advantage.

Another method, well worthy of more frequent use, consists in wheeling the barrows of concrete to a gallows frame where they are raised by a horse, and when wheeled to place.

In building railway abutments, culverts, and the like, it is often desirable to locate the mixing board on high ground, perhaps at some little distance from the forms. If this can be done, the use of derricks may be avoided as above suggested or by building a light pole trestle from the mixing board to the forms. The concrete can then be wheeled in barrows and dumped into the forms. If the mixing board can be located on ground as high as the top of the concrete structure is to be, obviously a trestle will enable the men to wheel on a level runway. Such a trestle can be built very cheaply, especially where second-hand lumber, or lumber that can be used subsequently for forms is available. A pole trestle whose bents are made entirely of round sticks cut from the forest is a very cheap structure, if a foreman knows how to throw it together and up-and the bents after they are made. I have put up such trestles for 25 cts. per lin. ft. of trestle, including all labor of cutting the round timber, erecting it, and placing a plank flooring 4 ft. wide on top. The stringers and

flooring plank were used later for forms, and their cost is not included. A trestle 100 ft. long can thus be built at less cost than hauling, erecting and taking down a derrick; and once the trestle is up it saves the cost of operating a derrick.

Concrete made with Portland cement (but not with natural cement) can be hauled long distances in a cart or wagon before it begins to harden. This fact should be taken advantage of by contractors far oftener than it is. I am inclined to think that the extensive use of natural cement, which sets too quickly to admit of hauling far, has blinded contractors to the possibilities of saving money by hauling Portland cement concrete long distances. Since a cart is readily hauled at a speed of 200 ft. a minute, where there are no long steep hills, it is evident that in $6\frac{1}{2}$ minutes a cart can travel a quarter of a mile; in 12 minutes, half a mile; and in 24 minutes, a mile. Portland cement does not begin to set for 20 minutes; hence it may be hauled a mile after mixing it. The cost of hauling concrete with one-horse dump-carts is practically the same as the cost of hauling its dry ingredients.

Cost of Dumping, Spreading and Ramming.—The cost of dumping wheelbarrows and carts is included in the rules of cost already given, excepting that in some cases it is necessary to add the wages of a man at the dump who assists the cart drivers or the harrow men. Thus in dumping concrete from barrows into a deep trench or pit, it is usually advisable to dump into a galvanized iron hopper provided with an iron pipe chute. One man can readily dump all the barrows that can be filled from a concrete mixer in a day, say 150 cu. yds. At this rate of output the cost of dumping would be only 1 ct. per cu. yd., but if one man were required to dump the output of a small gang of men, say 25 cu. yds., the cost of dumping would be 5 cts. per cu. yd.

Concrete dumped through a chute requires very little work to spread it in 6-in. layers; and, in fact, concrete that can be dumped from wheelbarrows, which do not all dump in one place, can be spread very cheaply; for not more than half the pile dumped from the barrow needs to be moved, and then moved merely by pushing with a shovel. Since the spreader also rams the concrete, it is difficult to separate these two items. As nearly as I have been able to estimate this item of spreading "dry" concrete dumped from wheelbarrows in street paving work, the cost is 5 cts. per cu. yd. If, on the other hand, nearly all the concrete must be handled by the spreaders, as in spreading concrete dumped from carts, the cost is fully double, or 10 cts. per cu. yd. And if the spreader has to walk even 3 or 4 paces to place the concrete after shoveling it up, the cost of spreading will be 15 cts. per cu. yd. For this reason it is apparent that carts are not as economical as wheelbarrows for hauling concrete up to about 200 ft., due to the added cost of spreading material delivered by carts.

The preceding discussion of spreading is based upon the assumption that the concrete is not so wet that it will run. Obviously

where concrete is made of small stones and contains an excess of water, it will run so readily as to require little or no spreading.

The cost of ramming concrete depends almost entirely upon its dryness and upon the number of cubic yards delivered to the rammer. Concrete that is mixed with very little water requires long and hard ramming to flush the water to the surface. The yardage delivered to the rammer is another factor, because if only a few men are engaged in mixing they will not be able to deliver enough concrete to keep the rammer properly busy, yet the rammer by slow though continuous pounding may be keeping up an appearance of working. Then, again, I have noticed that the slower the concrete is delivered the more particular the average inspector becomes. Concrete made "sloppy" requires no ramming at all, and very little spading.

I have had men do very thorough ramming of moderately dry concrete for 15 cts. per cu. yd., where the rammer had no spreading to do, the material being delivered in shovels. It is rare indeed that spreading and ramming can be made to cost more than 40 cts. per cu. yd., under the most foolish inspection, yet one instance is recorded below of even higher cost.

If engineers specify a dry concrete and "thorough ramming" they would do well also to specify what the word "thorough" is to mean, using language that can be expressed in cents per cubic yard. It is a common thing, for example, to see a sewer trench specification in which one tamper is required for each two men shoveling the back-fill into the trench; and some such specific requirement should be made in a concrete specification if close estimates from reliable contractors are desired. Surely no engineer will claim that this is too unimportant a matter for consideration when it is known that ramming can easily be made to cost as high as 40 cts. per cu. yd., depending largely upon the whim of the inspector.

Example of High Cost of Tamping.—Mr. Herman Conrow is authority for the following data: 1 foreman, 9 men mixing, 1 ramming, averaged 15 cu. yds. a day, or only $1\frac{1}{2}$ cu. yds. per man per day, when laying wet concrete. When laying dry concrete the same gang averaged only 8 cu. yds. a day, there being 4 men ramming. With foreman at \$2 and laborers at \$1.50 a day, the cost was \$2.12 per cu. yd. for labor on the dry concrete as against \$1.13 per cu. yd. for the wet concrete. Three turnings of the stone with a wet mortar effected a better mixture than four turnings with a dry mortar. The ramming of the wet concrete cost 10 cts. per cu. yd., whereas the ramming of the dry concrete cost 75 cts. per cu. yd. I think this is the highest cost on record for ramming. It is evident, however, that the men were under a poor foreman, for an output of only 15 cu. yds. per day with 10 men is very low for ordinary conditions. Moreover, the high cost of ramming indicates either poor management or the most foolish inspection requirements.

Cost of Rolling and Finishing Concrete Floors.—I am indebted to Mr. Ernest L. Ransome for the following:

When concrete floors are built directly on the ground, there is no necessity of having a concrete as rich in cement as when the floor spans an opening. A mixture of 1 part Portland cement, 4 parts sand and 8 parts gravel or broken stone is strong enough, and this requires less than three-quarters of a barrel of cement per cubic yard. If hand mixing is used, more cement is needed, but we are assuming that the materials are thoroughly mixed. Actual tests have demonstrated that more cement is required with hand mixing than with machine mixing.

The concrete should be spread in a layer 3 to 5 ins. thick, depending upon the nature of the subsoil and the loads the floor will have to support. Then the concrete should be rolled, for rolling is more effective than tamping and costs far less. The first attempts at rolling were unsuccessful because a roller of too great weight was used. Mr. Ransome discovered that a light roller should be used for the first rolling, followed by rolling with a heavier roller, and finishing with a roller still heavier.

The Ransome Concrete Machy. Co., of Dunellen, N. J., makes rollers of three sizes to be used successively, weighing: No. 1, 290 lbs.; No. 2, 375 lbs.; No. 3, 645 lbs.

One laborer will readily roll 7,500 sq. ft. in a 9-hr. day. If the floor is 4 ins. thick, this is equivalent to nearly 100 cu. yds. With wages at \$1.50 a day, the cost is 0.2 ct. per sq. ft., or 1½ cts. per cu. yd. for the rolling.

An interesting fact about rolling concrete is this: The water is flushed to the surface and may even run off in a thin stream, but the water is perfectly clear, carrying no cement in suspension. Whereas, when concrete is tamped, the water is milky, due to the cement that is flushed to the surface.

After the concrete is rolled, a finishing coat of mortar is applied.

Most contractors have finished floors with a coating of cement mortar immediately following the laying of the body of the floor. There are several objections to this practice. In the first place, should a heavy rain fall before the floor is roofed over, the surface will be damaged. This objection, however, is not so serious as another. Scaffolding placed on green concrete mars its surface, and, in addition to this, drippings of mortar and concrete from above spoil the surface. Moreover, it is very difficult to put a finishing coat on reinforced concrete floors when they are still soft. To escape these objections Mr. Ransome invented "Ransomite," which is a liquid that causes new concrete to adhere to old. The body of a concrete floor is built, as above described, and the finishing coat is not put on until the scaffolding and forms are removed from above. Then the floor is given a wash of "Ransomite," at a cost of approximately ¼ ct. per sq. ft. for material and labor. Upon the floor is spread a layer of cement mortar ½ to 1 in. thick, the mortar being 1 part Portland cement to 2 parts sand.

A skilled finisher at \$4 a day, with a helper at \$2.50, will finish 500 sq. ft. of floor in a day. Considerably more than 1,000 sq. ft.

a day have been finished by a skillful and willing man, but, assuming only 500 sq. ft. a day, the cost of finishing is about $1\frac{1}{4}$ cts. per sq. ft.

For further data on finishing floors, see the part of the section on Roads and Pavements where costs of cement walks are given.

Cost of Superintendence.—This item is obviously dependent upon the yardage of concrete handled under one foreman and the daily wages of the foreman. If a foreman receives \$3 a day and is handling a job where only 12 cu. yds. are placed daily, we have a cost of 25 cts. per cu. yd. for superintendence. If the same foreman is handling a gang of 20 men whose output is 50 cu. yds., the superintendence item is only 6 cts. per cu. yd. If the same foreman is handling a concrete-mixing plant having a daily output of 150 cu. yds., the cost of superintendence is but 2 cts. per cu. yd. I have given these elementary examples simply because figures are more impressive than generalities, and because it is so common a sight to see money wasted by running too small a gang of men under one foreman.

Of all classes of contract work, none is more readily estimated day by day than concrete work, not only because it is usually built in regular shapes whose volumes are easily ascertained at the end of each day, but because a record of the bags, or barrels, or batches gives a ready method of computing the output of each gang. For this reason small gangs of concrete workers need no foreman at all, provided one of the workers is given command and required to keep tally of the batches. If the efficiency of a gang of 6 men were to fall off, say, 15%, by virtue of having no regular non-working foreman in charge, the loss would be only \$1.35 a day—a loss that would be more than counterbalanced by the saving of a foreman's wages. Indeed, the efficiency of a gang of men would have to fall off 25%, or more, before it would pay to put a foreman in charge. I know by experience that in many cases the efficiency will not fall off at all, provided the gang knows that its daily progress is being recorded, and that prompt discharge will follow laziness. Indeed, I have more than once had the efficiency increased by leaving a small gang to themselves in command of one of the workers who was required to punch a hole in a card for every batch.

To reduce the cost of superintendence there is no surer method than to work two gangs of 18 to 20 men, side by side, each gang under a separate foreman who is striving to make a better showing than his competitor. This is done with marked advantage in street paving, and could be done elsewhere oftener than it is.

In addition to the cost of a foreman in direct charge of the laborers, there is always a percentage of the cost of general superintendence and office expenses to be added. In some cases a general superintendent is put in charge of one or two foremen; and, if he is a high-salaried man, the cost of superintendence becomes a very appreciable item.

Summary of Costs of Making Concrete by Hand.—Having thus

analyzed the costs of making and placing concrete, we can understand why it is that printed records of costs vary so greatly. Moreover, we are enabled to estimate the labor cost with far more accuracy than we can guess it; for by studying the requirements of the specifications, and the local conditions governing the placing of stock piles, mixing boards, etc., we can estimate each item with considerable accuracy. My purpose, however, has not been solely to show how to predict the labor cost, but also to indicate to contractors and their foremen some of the many possibilities of reducing the cost of work once the contract has been secured. I have found that an analysis of costs, such as above given, is the most effective way of discovering unnecessary "leaks," and of opening one's eyes to the possibilities of effecting economies in any given case.

To indicate the method of summarizing the costs of making concrete by hand, let us assume that the concrete is to be put into a deep foundation requiring wheeling a distance of 30 ft.; that the stock piles are on plank 60 ft. distant from the mixing board; that the specifications call for 6 turns of gravel concrete thoroughly rammed in 8-in. layers; and that a good sized gang of, say, 16 men (at \$1.50 a day each) is to work under a foreman receiving \$2.70 a day. We then have the following summary by applying the rules already given:

	Per cu. yd. concrete.
Loading sand, stone and cement.....	\$.17
Wheeling 60 ft. in barrows (4 + 2 cts.).....	.06
Mixing concrete, 6 turns at 5 cts.....	.30
Loading concrete into barrows.....	.12
Wheeling 30 ft. (4 + 1 ct.).....	.05
Dumping barrows (1 man helping barrowman) ..	.05
Spreading and heavy ramming.....	.15
Total cost of labor.....	\$.90
Foreman at \$2.70 a day.....	.10
Grand total.....	\$1.00

To estimate the daily output of this gang of 16 laborers proceed thus: Divide the daily wages of all the 16 men, expressed in cents, by the labor cost of the concrete in cents, the quotient will be the cubic yards output of the gang. Thus, $2,400 \div 90$ is 27 cu. yds. in this case.

In street paving work where no man is needed to help dump the wheelbarrows, and where it is usually possible to shovel concrete direct from the mixing board into place, and where half as much ramming as above assumed is usually satisfactory, we see that the last four labor items instead of amounting to $12 + 5 + 5 + 15$, or 37 cts., amount only to one-half of the last item, $\frac{1}{2}$ of 15 cts., or 7½ cts. This makes the total labor cost only 60 cts. instead of 90 cts. If we divide 2,400 cts. (the total day's wages of 16 men) by 60 cts. (the labor cost per cu. yd.), we have 40 which is the cubic yards output of the 16 men. This greater output of the 16 men reduces the cost of superintendence to 7 cts. per cu. yd.

Cost of Mixing Concrete With Machine.—Care must be taken not to confuse the cost of mixing concrete with the cost of delivering materials to the mixer and conveying the concrete away from the mixer. A study of the various costs given on subsequent pages will show that the cost of mixing alone is only a small part of the total cost of making concrete.

If all the materials are delivered to the machine in wheelbarrows, and if the concrete is conveyed away in wheelbarrows, the cost of making concrete, even with machine mixers, is high. On the other hand, where the materials are fed from bins by gravity into the mixer, and where the concrete is hauled away in cars, the cost of making the concrete may be very low.

There are three types of mixers: (1) Batch mixers; (2) continuous mixers; (3) gravity mixers. Cube mixers, double-cone mixers, and drum mixers are batch mixers in which a charge is rotated for 10 or 15 turns and then discharged all at once. The continuous mixers have paddles or plows that stir up the materials as fast as they are delivered, a continuous stream of concrete being discharged. In one type of gravity mixer the falling materials strike baffle plates which perform the mixing. In the more common type (the Hains), the materials pass through three funnel-shaped hoppers, the hour glass action causing the mixing.

Batch mixers are commonly made in three sizes, $\frac{1}{2}$ -yd., $\frac{3}{4}$ -yd. and 1-yd. It is generally considered sufficient to give the mixer 10 or 15 turns, occupying 1 to $1\frac{1}{4}$ mins., after charging it with a batch; but as some time is consumed in charging and discharging, etc., it is safe to count on only one batch every 2 mins., or 200 batches in 10 hrs. If each batch is $\frac{1}{2}$ -yd., the daily output is 100 cu. yds.; if the batch is 1 yd., the daily output is 200 cu. yds.

Where the work is well organized, and no delays occur in delivering the materials to the mixer, a batch every 2 mins., or 200 batches in 10 hrs., will be averaged; and there are a few records of 1 batch every $1\frac{1}{2}$ mins., and even less.

Not more than 12 hp. are required to run a $\frac{3}{4}$ -yd. mixer. Where materials are delivered from bins or skips, 2 men will charge a $\frac{3}{4}$ -yd. mixer and 1 man will attend to dumping it, and a gasoline engine consuming 10 gals. of gasoline per 10-hr. day at $12\frac{1}{2}$ cts. per gal., will represent the full cost of labor and fuel for mixing 200 cu. yds. If the 2 men are paid \$1.50 each, and 1 man at \$1.75, the cost of labor and fuel is only \$6.00, or 3 cts. per cu. yd. It is not in the *mixing*, therefore, that the money is consumed, but in conveying materials to and from the mixer, in ramming the concrete, in installing the plant for mixing and conveying, and in interest and depreciation charges.

For tables of sizes, weights, capacities, etc., of mixers made by 11 different manufacturers, see Gillette and Hill's "Concrete Construction," p. 460, etc.

A batch mixer will, in general, require the following engine power :

	HP.
$\frac{1}{4}$ cu. yd. batch mixer.....	7
$\frac{1}{2}$ cu. yd. batch mixer.....	10
$\frac{3}{4}$ cu. yd. batch mixer.....	14
1 cu. yd. batch mixer.....	20

It is wise to provide a boiler power about 50% in excess of the engine power.

The weights of batch mixers, with and without engine and boiler, seldom exceed the following:

Size of batch, cu. yd.....	$\frac{1}{4}$	$\frac{1}{2}$	$\frac{3}{4}$	1
Weight of mixer on skids, lbs.....	3,500	3,800	6,000	6,700
Ditto with engine and boiler, lbs....	7,000	7,500	12,000	13,500

Prices vary considerably, but, for purposes of estimating, assume about 10 cts. per lb.

The above sizes of "batches" are based not upon the loose measure of the materials, but of the concrete rammed in place.

Cost of Mixing With a Gravity Mixer.—Mr. G. B. Ashcroft states that a small gravity mixer of the Hains type was used in the building of a dock for The William Skinner Ship-Building & Dry Dock Co., of Baltimore, Md. It consisted of two conical hoppers, one above the other, and above these were four small pyramidal hoppers for measuring the sand and stone, and above these were small bins. One man at each conical hopper tending the gates, and two men at the pyramidal hoppers (4 men in all) constituted the gang on the mixer. A scow load of sand and another of broken stone were hauled alongside the bulkhead on which the mixer stood, and a clamshell bucket dredge was used to load the sand and stone from the scows into the bins of the mixer. Each batch was 25 cu. ft. of 1:3.5 concrete rammed into place. The record for 10 hrs. was 110 batches, making about 15 cts. per cu. yd. as the labor cost. Wages of common laborers were \$1.50. The concrete was run directly into place through chutes; and the mixer was moved from place to place by means of the dredge boom.

On the Cedar Grove Reservoir, built for Newark, N. J., a large gravity mixer of the Hains type was used. The best day's output was 403 cu. yds.; the average output during the best month was 302 cu. yds.; and the average of the whole job was 225 cu. yds. per 10-hr. day. The stone, sand and cement were all raised by bucket elevators to the top of the high wooden tower that supported the bins and the mixer. There were 10 men operating the mixer, so that (exclusive of power, interest and depreciation) the labor cost of mixing averaged only 7 cts. per cu. yd.; and during one month it was as low as 5 cts. per cu. yd. This does not include delivering the materials to the men at the mixer, nor does it include conveying the concrete away and placing it. The work was done by contract.

On the Pittsburg filter construction in 1906, a Hains mixer was used, and its output was 500 cu. yds. per 10-hr. day.

Cost of Forms.—It is a common practice to record the cost of forms or molds in cents per cubic yard of concrete, giving separately the cost of lumber and labor. This should be done, but the analysis of the cost of forms should always be carried a step farther. The

records should be so kept as to show the first cost per M (i. e., 1,000 ft. B. M.) of lumber, the number of times the lumber is used, the labor cost of erecting, and the labor cost of taking down the forms each time—all expressed in M ft. B. M. Thus only is it possible to compare the cost of forms on different kinds of concrete work, and thus only can accurate predictions be made of the cost of forms for concrete work having dimensions differing from work previously done. It is well also to make record of the number of square feet of exposed concrete surface to which the forms were applied. There are three ways, therefore, of recording the cost of forms: (1) In cents per cubic yard of concrete; (2) in cents per square foot of concrete face to which forms are applied; and (3) in dollars per M ft. B. M. of lumber used—in all three cases keeping the cost of materials and labor separate. Furthermore, it is well to make a sketch of the construction of the forms, and attach the sketch to the record of cost.

In estimating the probable cost of forms I find the following method most reliable: First, after ascertaining the time limit within which the work must be completed, determine the number of cubic yards of concrete that must be laid each day, after allowing liberally for delays. Knowing the number of cubic yards, estimate the number of thousand feet board measure of forms required to encase the concrete to be placed in a day. This will give the minimum amount of lumber required, for it is never permissible to move the forms until the concrete has hardened over night, except when concrete is in a small arch, as in a sewer. This brings us to a very important question in economics. Thousands of words have been written on the advantages and disadvantages of using "wet" or "dry" concrete, but I have never seen mention of one of the most forceful objections to the use of concrete mixed so wet that it is sloppy. I refer to the slowness with which such concrete hardens. Obviously, the more slowly it hardens, the longer must the forms be left in place; and the longer the forms are left in place the more lumber will be required; the more the lumber, the greater the cost of forms per cubic yard of concrete.

A concrete mixed "dry," and rammed, will harden over night, so that in retaining wall construction it is safe to remove the forms the next morning; but, where the concrete has been mixed "sloppy," I have seen whole sections of wall fall out upon the removal of forms twelve hours after placing the concrete. In cold weather the setting is further delayed, and in very cold weather it may cease entirely unless proper precautions are taken. Specifications relating to sloppy concrete usually provide that wall forms shall not be moved within 48 hrs. after placing the concrete; but in hot weather it is often safe to remove the forms in 24 hrs. or less.

Forms for concrete arches or beams must obviously be left in place longer than in wall work, because of the tendency to fall by rupture across the arch or beam. Forms for small circular arches, like sewers, may be removed in 18 to 24 hrs. if dry concrete is used; but in 24 to 48 hrs. if wet concrete is used. Forms for large arch

culverts and arch bridges are seldom taken down in less than 14 days, and it is often specified that they must not be struck for 28 days after placing the last of the concrete. This last requirement is probably necessary where the backfilling over the arch is put on at once; but, except in the case of arches of great span, there appears to be no sufficient reason for keeping the centers so long under the arch, provided they can be used elsewhere. Indeed, I am inclined to think that a week's time is ample for arches having a span of 40 ft. or less, provided no filling is placed on the arch. In fact, a study of the compressive strength tests given in Falk's "Cements, Mortars and Concretes," pages 128, 131, etc., shows that the difference of compressive strength between 7-day and 28-day Portland cement mortar and concrete is often less than 25%, and averages about 50%; and that in any case concrete a week old is amply strong enough to hold its own weight in an arch of moderate size. Progressive settlement of the abutments might in some cases be given as a reason for leaving centers a long time in place, but abutments founded on rock or on piles do not show progressive settlement after the striking of centers, unless the subsequent jarring of trains causes the piles to go down.

Forms supporting concrete-steel floors and beams are usually left in a place at least a week.

The consideration of the time element in the use of forms is essential in making an accurate forecast of the quantity of lumber that will be required in any given case. A few additional suggestions will not, therefore, be out of place.

Often the uprights of studs used to hold the sheeting plank are also used as legs for a trestle to support a track or runway over which the concrete is transported. In such a case the amount of timber in the forms is considerably more than would be indicated by considering merely the length of time that the forms must stand before removal; for, so long as the uprights stand, it is impossible to remove the sheeting plank where ordinary kinds of forms are used. I have seen many instances of unnecessary expenditure of money for forms due to neglect to consider this fact. Bear in mind, therefore, that it may be cheaper to provide a movable derrick, or to use a cableway for delivering the concrete, rather than to use the uprights of the forms as posts for a trestle.

I have found it cheaper, as a rule, to build the coping of retaining walls after finishing the wall itself. One of the reasons for this is that a projecting coping is apt to fall, due to its own weight, if the forms are not left in place longer than it is necessary to leave the forms for the wall below the coping.

This leads us to the subject of building forms in panels that can be shifted from place to place without tearing the forms to pieces and building them up again. When panels can be used, it is evident that the cost of labor and lumber for forms may be reduced to a few cents per cubic yard of concrete. Examples of low cost of sewer work where the forms are thus shifted in sections will be found on

subsequent pages. Even high retaining walls may thus be built with movable forms.

There are few classes of concrete work where, at the expense of a little thought in designing movable forms, a great expense in lumber may not be saved.

Having estimated the quantity of lumber required for any given concrete job, and the number of times that it can be used, the labor cost of framing, erecting and taking down the forms may be calculated thus: With carpenters' wages at 25 cts. per hour, and laborers' wages at 15 cts. per hour, working 1 laborer to 3 carpenters, my records show that ordinary forms for walls, arches, etc., can be framed and erected for \$6 per M ft. B. M., when men are working for a contractor. The forms can be carefully torn apart, taken down and moved a short distance, for \$1.50 per M; making the total labor cost \$7.50 per M for each time that the forms are built up and torn down. Where the forms are built in panels and are not ripped apart and nailed together again at every move, there is only the cost of moving them each time after they have once been built, and this may not exceed 50 cts. per M for each move. Moreover forms used in panels last much longer since the lumber is not injured by being repeatedly torn apart.

Retaining walls, bridge piers and abutments, etc., are commonly provided with forms consisting of 2-in. plank laid in horizontal courses against upright studs. The studs may be of 4 x 6-in. stuff spaced 2½ ft. centers, or 3 x 6-in. spaced 2 ft. centers. In either case the lumber in the studs is about 40% as much as the lumber in the 2-in. sheeting plank. Hence there are 2 ft. B. M. of plank and 0.8 ft. B. M. of studs, or a total of 2.8 ft. B. M. for each square foot of surface area of concrete. If telegraph wire is used to hold the studs from spreading (No. 9 wire weighing 0.06 lb. per ft.), no other lumber is required; but in some designs of forms there are inclined braces against the stud, frequently containing more lumber than the studs themselves. Ordinarily the same forms are used several times, so that the 2.8 ft. B. M. per sq. ft. does not then mean per sq. ft. of concrete, but of forms, and must be divided by the number of times it is used to estimate the lumber per sq. ft. of concrete surface. Thus, if the forms are used 4 times, we have $2.8 \div 4 = 0.7$ ft. B. M. per sq. ft. of concrete surface.

If lumber costs \$25 per M, the cost of 2.8 ft. B. M. is 7 cts. It can usually be framed and erected for \$8 per M, or 2½ cts. per sq. ft. of forms containing 2.8 ft. B. M. Hence if the lumber is used 4 times, we have $7 \div 4 = 1\frac{3}{4}$ cts., cost of lumber per sq. ft. of concrete, plus 2½ cts. per sq. ft. for labor if each time it is taken down and erected costs \$8 per M, or a total of 4 cts. per sq. ft. of concrete surface, or 36 cts. per sq. yd. Hence if the wall is 3 ft. thick and requires forms on two faces (front and rear) it will cost 2×36 cts. = 72 cts. for forms per cu. yd. of concrete. If it is 6 ft. thick, it will cost 36 cts. per cu. yd. of concrete. If the same sizes of lumber were used for a wall only 1 ft. thick, the cost would be \$0.36 \times

\$ = \$1.08 per cu. yd. Based upon the above assumptions as to amount and cost of lumber, number of times used (4), etc., we have the following rule:

To ascertain the cost of forms per cubic yard of wall, divide \$2.16 by the thickness of the wall in feet.

This rule can be expressed in a more general form as follows:

To ascertain the cost of forms per cubic yard of wall, divide \$3.20 by the product of the thickness of wall in feet and the number of times the forms are used, to estimate the cost of lumber, and to this add the cost of labor determined by dividing \$1.20 by the thickness of the wall in feet.

In the case of a 3-ft. wall where forms are used 4 times, this rule would give us:

$\$3.20 \div (3 \times 4) = \0.32 for lumber, to which add $\$1.20 \div 3 = \0.40 for labor, making a total of \$0.72 per cu. yd.

For any other price and amount of lumber for forms, a similar rule can readily be made. Such a rule shows very clearly the reason why thin concrete walls where form lumber is used only once or twice cost so much per cubic yard. Thus, if a wall were only 1 ft. thick and lumber were used but once, the above rule would give us a cost of \$5 per cu. yd. for forms alone.

For further data on the cost of forms see particularly the sections on Buildings, Bridges, and Sewers. Consult the index under "Concrete, Forms."

Cost of Fortification Work at Fort Point, Cal.—Mr. George H. Mendell gives the following data: The work was the construction of fortifications at Fort Point, near San Francisco. The following experiments were made:

	Experiment		
	No. 1	No. 2	No. 3
	cu. ft.	cu. ft.	cu. ft.
1 bbl. Portland cement measured loose.....	4.42	4.58	4.5*
Water added.....	2.00	1.75	1.92
Volume of stiff paste resulting.....	4.90	3.80	3.82
Moist sand added.....	19.12	11.40	13.50
Water added.....	2.00	2.50	2.00
Volume of mortar resulting.....	10.12†	12.80	14.00
Gravel added‡.....	36.50	36.90
Volume of loose concrete.....	46.25	49.23
Volume of concrete tamped in place.....	37.50

*This barrel measured $3\frac{1}{2}$ cu. ft. packed.

†There is some doubt as to the accuracy of this measurement, for it was recorded as 9.12 cu. ft. although it was probably 10.12.

‡This gravel in experiment No. 1, was in $\frac{3}{4}$ -in. sizes down to birdshot; in experiment No. 2 it was the size of beans and smaller. There was a considerable percentage of what should be called sand in the gravel, probably 20%.

In making the concrete all materials were measured loose and a barrel of cement was assumed to measure $4\frac{1}{2}$ cu. ft. The proportions of a batch were 1:3:8; the 8 being $8 \times 4\frac{1}{2}$, or 36 cu. ft. of stone and gravel. In making a mass of concrete 60 ft. long, 40 ft.

wide and 30 ft. high, a careful record was kept of the cost of several weeks' work, measuring 1,825 cu. yds. in place:

	Cost, per cu. yd.
0.73 bbl. cement at \$2.50.....	\$1.82
0.83 cu. yd. stone.....	1.40
0.26 cu. yd. gravel.....	.35
0.31 cu. yd. sand.....	.29
Water04
Crushing stone,* mixing and placing concrete....	.80
Total	\$4.70

*While it is not definitely stated I infer from what is said that the labor of crushing was about 15 cts.

Wages were \$2 per day of 8 hrs. for laborers, and \$4 for foremen. The cost of timbering and incidental expenses is not included, other than the pay of the men and the foreman. The total volume of all the loose materials, exclusive of the water, was 2,767 cu. yds. before mixing; after mixing, and measured in cars holding 20 cu. ft. each, the volume was 2,433 cu. ft.; after being rammed in place the volume was 1,825 cu. yds. The shrinkage of the concrete under the ramming was therefore 25%. A number of experiments were made on single carloads which showed that a carload of 30 cu. ft. of loose concrete made 15 to 15½ cu. ft. compacted in place.

The stone was quarried at Angel Island, and delivered on the wharf in sizes suitable for a Gates crusher, hauled in wagons to the crusher, which delivered it to the mixer, into which all the ingredients were fed from hoppers automatically. The mixer was of the cylindrical continuous type, and there was difficulty in delivering the materials to it automatically and in the desired proportions. The concrete was delivered by the mixer into cars holding 20 cu. ft. When a car was filled, the door of the mixer was closed for a minute, during which minute another car was put in place, the concrete in the meantime accumulating in the mixer. The cars were pushed by men to the place of deposit, a variable distance of 800 to 600 ft., and discharged through a trestle having an extreme height of 30 ft., gradually diminishing to 4 ft. The concrete was then shoveled into wheelbarrows and wheeled 20 to 40 ft.

During the month of August, 1892, concrete was mixed by hand by a gang of 20 men under 1 foreman. The average 8-hr. output was 45 cu. yds. of concrete at a cost of \$1 per cu. yd. for mixing and placing, wages being \$2 a day. A batch consisted of 4 bbls. of cement and 144 cu. ft. of gravel and stone, giving 144 cu. ft. of concrete. The materials were piled conveniently around the mixing platform. The stone and gravel were delivered in barrows and spread to an even thickness on the platform. Upon this the sand was wheeled and spread with a straight edge. The cement, also leveled, formed the top layer. Water was added in the turning. The materials were turned twice with shovels, being well dispersed in turning. A third turning resulted from shoveling the concrete into wheelbarrows, and a fourth turning in distributing the concrete.

There was no ascent and the distances were short in wheeling the concrete, and the men were a picked lot.

Cost of Fortification Work.—Mr. L. R. Grabill is authority for the following cost data: The work was upon fortifications built in 1839 for the U. S. Government, and was done by contract, working 8 hrs. per day. The following is the average for 9,000 cu. yds.:

	Per day.	Per cu. yd.
6 laborers wheeling materials to board.....	\$ 7.50	\$0.16
8 laborers mixing	10.00	.21
8 laborers wheeling away.....	10.00	.21
6 laborers placing and ramming.....	7.50	.16
1 pumpman	1.25	.02
1 water boy	1.00	.02
1 foreman	2.00	.04
Total, 48 cu. yds. a day.....	\$39.25	\$0.82

Each batch contained $\frac{3}{4}$ cu. yd. of 1:2:2:3 concrete, and was turned four times.

The cost of mixing 4,000 cu. yds. in a machine mixer by day labor (not by contract) was as follows:

	Per day.	Per cu. yd.
32 laborers	\$40.00	\$0.34
1 pumpman	1.25	.01
1 teamster and horse.....	2.00	.02
2 water boys	2.00	.02
1 engineman	1.70	.02
1 derrick tender	1.50	.01
1 fireman	1.50	.01
1 foreman	2.88	.03
Fuel (cement barrels largely)	1.25	.01
Total, 118 cu. yds. per day.....	\$54.08	\$0.47

The average 8-hr. day's work was 168 batches of 0.7 cu. yd. each. The best day's work was 200 batches. Seven revolutions of the 4-ft. cubical mixer were sufficient. A 12-hp. engine operated the mixer and served also to hoist the material cars up the incline to the mixer. These cars were loaded through trap doors in a bin containing the materials, then the cement was placed upon the load. The material cars moved up one incline, dumped, and passed down another incline on the opposite side. The concrete was dumped into an iron bucket resting on a car, hauled to one of the two boom derricks. These derricks had 80-ft. booms and were swung by bull-wheels. This plant cost about \$5,000. The concrete was rammed in 6-in. layers in all cases; and it was found advisable to have one rammer to every 20 batches deposited per day, in addition to the spreaders.

Cost of Concrete Breakwater, Buffalo, N. Y.—Mr. Emile Low gives the following data on the cost of making concrete by contract for the Buffalo Breakwater, in 1902: A 5-ft. cubical mixer was mounted on a scow and run by a 9 x 12-in. horizontal engine. The concrete was 1:2:1:4 cement, sand, gravel and stone. The voids in the sand and gravel were 27%, in the unscreened limestone, 29%. A bag of cement was assumed to be 0.9 cu. ft. The materials were

stored in canal boats alongside. The sand was loaded by 3 shovelers into wheelbarrows holding 3.6 cu. ft. each, and wheeled in tandem to a steel charging bucket. Two more barrows, each holding 2.7 cu. ft. of gravel, were loaded and also dumped into the charging bucket; then 6 bags of cement ($1\frac{1}{2}$ bbls.) were emptied into the bucket. Another bucket was loaded with 21.6 cu. ft. of stone by 8 shovelers. These two buckets were hoisted by a derrick, in rapid succession, and dumped into the mixer. The dump man also attended to supplying water. A charging man started the mixer. The concrete was dumped from the mixer into a skip on a car below, by 2 men who pushed the car out where another derrick on the mixer scow hoisted it to the wall. There were 2 tagmen on each derrick to swing the booms, one paying out a tag rope while the other hauled in. A parapet wall, containing 841 cu. yds., was built in 46 hrs. actual work, 18.2 cu. yds. being placed per hour, each batch containing 1.07 cu. yds. of rammed concrete. A parapet deck, containing 1,720 cu. yds., was built in 88 hrs., or $19\frac{1}{2}$ cu. yds. per hr., each batch being 1.08 cu. yd. The labor cost of making this concrete (common labor being \$1.75 per 10 hrs.) was as follows:

	Concrete.	
	Cost, per 10-hr. day.	Cost, per cu. yd.
Loading gang:		
1 assistant foreman	\$ 2.00	\$0.011
3 cement handlers	6.25	0.029
3 sand shovelers	6.25	0.029
2 gravel shovelers	3.50	0.020
8 stone shovelers	14.00	0.075
1 hooker-on ..	1.75	0.010
Mixer gang:		
1 dumpman	1.75	0.010
1 charging man	1.75	0.010
2 car men	3.50	0.020
2 enginemen, at \$3.25	6.50	0.035
4 tag men, at \$2.00	8.00	0.044
1 fireman	2.00	0.011
Wall gang:		
1 signalman	1.75	0.010
1 dumper	1.75	0.010
6 shovelers, at \$2.00	12.00	0.065
4 rammers	7.00	0.038
1 foreman	4.00	0.022
Total (182 cu. yds. per day)	\$81.75	\$0.456

This cost of 45 cts. per cu. yd. does not include fuel, forms or plant rental.

Cost of Concrete Lock, Upper White River.*—Maj. Graham D. Fitch gives the following:

A lock (No. 1) was built on the Upper White River, at one end of a dam. The lock was built inside a cofferdam, the cost of which is given elsewhere (see index under Cofferdam). Wages of common laborers were \$1.50 per 8-hr. day. Work was done by Government forces.

**Engineering-Contracting*, May 6, 1908, p. 270.

The locks are of concrete masonry, 175 ft. long, between hollow quoins. The height of the lock walls is 15 ft. above the upper miter sill, 25 ft. above the lower sill and 30 ft. above the lock floor. Being founded on solid rock, each wall acts separately, and the design is that of a retaining wall. The land wall is slightly stronger than the river wall, but its top is narrow. Opposite the chamber it is stepped in the rear with 1-ft. offsets every $3\frac{1}{2}$ ft., while the river wall is battered. Both walls are $14\frac{1}{2}$ ft. thick at the bottom. At the top the thickness of the river wall is 6 ft., and of the land wall is 4 ft. 9 ins. The ends of the lock walls are necessarily thicker than the side walls of the chamber, as they must not only support the pressure from the gates but also provide work room for the lock tenders. The thickness of the lock walls at the heels of the gates was accordingly made 16 ft. The walls are in conformity with the usual practice, without batter inside. The available length of the lock chamber is 147 ft. and the width is 36 ft. The length of the wall below the lower quoin is 25 ft. and above the upper quoin 27. The total length of the lock is 237 ft.

The hollow quoins are shaped directly in the concrete, a form being used as for any other special surface. The shape is that of an arc of the same radius as the heel of the gate, namely, 10 ins.; they are 110 degrees in length, with tangents at either end 6 ins. long. The gate recesses are 22 ft. long and 2 ft. deep. The miter walls are without batter. Part of the lower miter wall is prolonged downstream to the lower end of the lock, so as to protect the tail bay from being scoured out by the discharge from the culverts.

The upper coffer wall, the function of which is to support a simple movable dam across the head of the lock when the upper gates or valves need repairing, has its sill 1 ft. below the upper miter sill. In coffering the head bay this sill forms the lower support for the needles used, the top support being a trussed beam, the ends of which rest in slots in the main walls at such an elevation that the trussed beam will be as low as possible without being immersed at ordinary low-water stages. A similar arrangement of slot and sill is provided for coffering the tail bay. With the object of preventing the water from cutting behind the land wall, its upper and lower end is, in each lock, provided with a wing wall running perpendicularly back into the bank far enough to join the rocky bluff which is from 20 to 30 ft. in the rear. The thickness of these walls is 4 ft. 9 ins. on top, increasing downward by offsets until rock foundation is reached.

There are two filling culverts each 3 ft. 3 ins. by 7 ft., which are placed in the gate recesses to keep them from filling with mud; these culverts discharge into a large cross culvert in the upper miter wall and thence through 8 small lateral openings into the lock chamber, thus dividing the water into small streams emptying near the lock floor so as to cause little disturbance to boats. For emptying the lock there are two side culverts, each 4 by 5 ft., which pass around the heels of the lower gates entering near the gate re-

cess and discharging below the miter wall into the tail bay, thus serving to prevent deposits there.

The forms used in the concrete work on the lock were of the usual type, namely, plank or lagging laid horizontally and held rigidly by outside posts, solidly braced to the ground so as to prevent the ramming from springing them. Yellow pine lumber was used. The lagging was 2 in. thick and 12 in. wide, and was dressed on all four sides. The posts were 4 x 6-in. scantling, spaced 4 ft. apart and were supported at about 8-ft. intervals by inclined braces of 4 x 6-in. scantling. The forms were built in separate alternate sections, the lagging for each section being carried to the full height before concreting was started in that section, and the concreting for each section of wall being completed before another section was begun, as the work was in two 8-hr. shifts, the sections are not monolithic. These posts of the forms were tied together at the top of two rows of $\frac{1}{2}$ -in. or $\frac{3}{4}$ -in. round iron tie-rods. Forms were left in position from four to five days after concreting was completed.

Cost of Forms.—The cost of the forms was as follows:

FORMS.			
Materials:	Unit Cost.	Total.	Per M ft.
Lumber, 159 M ft.....	\$11.40	\$1,818	\$11.40
Iron and nails	360	2.26
Total		\$2,178	\$13.66
Labor:			
Inspecting lumber, 15.6 M.....	.8897	6	.04
Hauling lumber	78	.49
Erecting, etc., 159 M ft.....	15.29	2,436	15.29
Total		\$2,514	\$15.72
Grand total (159 M ft).....		\$4,692	\$29.38

The total labor time in days in erecting, etc., was 1,218 $\frac{1}{2}$ days, and the work done per man per day was 130.5 ft. B. M.

Mixing.—The concrete mixer was a 4-ft. cubical box of $\frac{1}{2}$ -in. riveted steel securely fastened at diagonally opposite corners to a 3-in. steel shaft bored for about half its length with a 1-in. hole for the admission of water. Near one corner was a 15 x 20-in. hinged door for the admission of the dry materials. The mixer was operated by a center crank engine with 6 x 7-in. cylinder and was located on the bank approximately opposite the center of the lock. The concrete was placed by derricks. A Y track led from the mixer parallel to and about 18 ft. back of the land wall to within easy reach of two stiff-leg derricks, so located as to command the entire lock wall. The mixer charge was dumped into skips, which were taken from the cars by derricks and the concrete deposited in place in the lock walls. Upon the completion of the land wall the derricks were placed on this wall, where they commanded the river wall. The concrete was placed in layers 10 ins. thick.

In the concrete work Portland cement only was used, the brands being Lehigh and Alpha. The cement varied in price from \$1.82 to

\$2.70 per barrel delivered on cars at Birds Point, Mo.; from there it was transported as far as Newport, Ark., over a land-grant railroad, and from Newport to Batesville, the freight charges were approximately 11 cts. per barrel. The sand used was a coarse, sharp, clean sand from the Arkansas River, near Little Rock, and cost 23 cts. per cubic yard delivered at Little Rock. To this sum should be added 26 cts. for freight and 38 cts. for hauling from the Batesville depot to the lock site.

The gravel used was dredged by hired labor, from the river near the works; it consisted of a mixture of pebbles of all sizes with about 19% sand. It was not washed, as bars were found where the gravel contained only clean sand. This river gravel contained usually from 17 to 21% of voids. It cost delivered in bin, including all charges, 35 cts. per cu. yd. The stone used was a sandstone, the so-called bluestone of Cabin Creek, Arkansas, which, tested at Watertown Arsenal, had shown an ultimate strength of 17,700 to 19,700 lbs. per sq. in. It cost 70 cts. per cu. yd. at Cabin Creek; the freight charges amounted to 25 cts. per cu. yd. and the hauling from the depot to the works 60 cts. a cu. yd. All stone was broken into fragments small enough to pass through a 3-in. ring. The voids averaged 51%. The stone was required to be screened, though the run of the crusher would have been preferable.

The proportions of the mix varied, the concrete being richer in the foundations, on exposed surfaces, and when gravel was used. It was the intention to use crushed stone concrete for a depth of 4 ft. on all exposed surfaces and gravel concrete elsewhere, but in the construction of this lock, owing to the irregularity of the delivery of the stone, gravel concrete was used whenever necessary to avoid stopping the work. Three mixtures were used in the walls, depending upon the supply of materials on hand, viz.: 1 part cement, 2½ sand, and 6½ gravel; 1 part cement, 3 sand, 6½ gravel; 1 part cement, 3 sand, 4 gravel and 2 broken stone. Less sand was used with the straight gravel mixture than with the broken stone because of the large per cent of sand contained in the river gravel. The amount of water had to be varied frequently. It was regulated by judgment, according to the appearance of the mortar.

The cost of mixing and placing the concrete for the lock, was as follows:

Materials.	Unit Cost.	Total.	Per cu. yd. Concrete.
Cement, Lehigh, 4,051 bbla.....	\$2.45	\$ 9,925	\$1.12
Cement, Lehigh, 841 bbla.....	1.97	1,657	.18
Cement, Alpha, 4,992 bbla.....	2.20	10,982	1.24
Crushed stone, 2,256 cu. yds.....	.70	1,579	.17
Crushed stone, 92 cu. yds.....	3.25	299	.03
Sand, 3,096 cu. yds.....	.35	1,022	.11
Gravel, 12.9 cu. yds.....	.50	6	..
Fuel		537	.06
Illuminating oils.....		314	.03
Total materials.....		\$26,322	\$2.94

	Unit Cost.	Total	Per cu. yd. Concrete.
Labor.			
Mixer frame.....		\$ 153	\$0.017
Insp. of cement, 9,884 bbla.....	\$0.022	223	0.025
Inspect'n of crushed stone, 2,348 cu. yda.....	.101	238	.026
Insp. of sand, 3,096 cu. yda.....	.069	213	.024
Storing cement, 2,500 bbla.....	.079	199	.021
Hauling cement, 9,690 bbla.....	.08	775	.086
Hauling crushed stone, 2,078 cu. yda.....	.60	1,247	.140
Hauling sand, 3,053 cu. yda.....	.38	1,160	.130
Dredging gravel, 6,125 cu. yda.....	.105	646	.072
Unloading gravel for hand mixed concrete, 385 cu. yda.....	.181	70	.008
Holating gravel for machine mixed concrete, 5,025 cu. yda.....	.473	2,378	.266
Mixing and placing machine mixed concrete, 7,858 cu. yda.....	.563	4,464	.499

Tamping hand mixed concrete.....	1,081	283	3.83
Finishing top of lock wall.....	548	29 5/8	18.27

Valves, Ladders, Etc.—The valves in the culverts previously mentioned, are butterfly or balanced valves of steel plates and angles turning on vertical shafts. There are two valves to each filling culvert because the valves had to be of low height in order to remain submerged during low water. They are 3 ft. 2 ins. by 3 ft. 3 ins. in size. The wicket is set in a cast iron frame bolted to the concrete and is protected from debris by a movable screen sliding vertically in guides bolted to the walls. The valve operating gear, which is set in a covered recess in the coping, consists of a gear sector keyed to the top of the valve shaft and geared with a pinion turned by a ratchet wrench and wheel. Two recessed ladders are placed in each chamber wall of the lock.

The cost of the valves, ladders, etc., was as follows:

Materials.	Unit Cost.	Total.
New valves and foundry work on same, 2.....	\$561.00	\$ 534
Iron, wrought, 5,297 lbs.....	.06	324
Iron, cast, 7,737 lbs.....	.046	348
Steel, 6,376 lbs.....	.085	543
Total materials.....		\$1,749
Labor.		
Hauling, iron, etc.....		\$16
Placing 30,110 lbs.....	\$0.02	406
Total labor.....		\$ 422
Grand total.....		2,171

Summary of Lock Work:

	Total	Unit Cost.
Clearing site (4 acres).....	\$ 204	\$51.00
Cofferdam (462 lin. ft.).....	8,487	18.37
Excavation (3,636 cu. yds.).....	6,468	1.58
Forms (139 M. ft.).....	4,892	29.38
Concrete (8,333 cu. yds.).....	43,126	4.83
Gates and sills.....	5,569
Valves, ladders, etc.....	2,171
Filling behind land wall (4,262 cu. yds.).....	3,441	.806
Grading and paving same (1,916 sq. yds.).....	1,553	.810
Excavating upper approach.....	388
Excavating lower approach.....	182
Upper land crib (30 M. ft.).....	1,713	57.10
Lower land crib (93 M. ft.).....	806	26.66
Lower river crib (48.2 M. ft.).....	2,804	60.69
Upper river crib (47.6 M. ft.).....	2,761	58.00
Total	\$84,715	

For the cost of the lock gates, see the section on Timberwork and Piling. Consult the index under "Timberwork, Lock Gates."

Cost of Concrete Locks, Coosa River, Ala.—Mr. Charles Firth gives the following on the concrete locks on the Coosa River, Ala. Lock No. 21 has a length of 322 ft. between hollow quoins and a length of 420 ft. over all, with a width of 52 ft. in the clear. The lock walls are 34.7 ft. high and 16 ft. thick at the base. The total quantity of concrete was 20,000 cu. yds., requiring 21,500 bbls. of cement, half Atlas and half Alsen's. It was mixed 1:3:5½, the stone being crushed mica-schist. Two mechanical 4-ft. cube mixers were used, being driven by a 10 X 16 engine. Each batch consisted of 3 cu. ft. cement, 9 cu. ft. sand and 16½ cu. ft. stone, and was turned 4 times before and 6 times after adding the water, at a speed not exceeding 8 revolutions per minute. The top floor of the mixing house had a storage capacity of 2,000 bbls. of cement. The sand and stone were delivered in side dump-cars. The concrete was delivered into bottom-dump cars. The average output of these two mixers was 200 cu. yds. in 8 hrs., or 100 cu. yds. per mixer, but it was limited by the means of placing the concrete. Each batch of concrete measured 24 cu. ft. in the car, but it shrank 20% when rammed in place, so that it required 34 cu. ft. of concrete in the cars to make 1 cu. yd. in place. The concrete was mixed quite dry and rammed in 6 to 8-in. layers, using 30-lb. iron rammers having a square face 6 ins. on a side. On all exposed surfaces a 1:3 mortar was placed as the work progressed, making a thickness of 6 ins. of mortar. To

do this 2 × 12-in. planks were placed 4 ins. away from the forms, being kept at that distance by 2 × 4-in. strips of wood. After the backing concrete was in place and partly rammed, these planks were removed and the 6-in. space filled with mortar. The walls were carried up in lifts, each lift being completed all around the dock before the next was commenced. The first was 10.7 ft. high, each succeeding lift was 6 ft., except the last which was 4.5 ft., exclusive of the 18-in. coping. The coping was 6 ft. wide and made in separate blocks 3 ft. long, which were placed after the walls were completed. The coping was 1:2:3 concrete, faced with 1:1 mortar, and was cast in blocks face down, its edges being rounded to a 3-in. radius. The sides of the molds for these blocks were removed 3 days after making, and 10 days later the blocks were stacked away.

In building the forms 6 × 8-in. posts 24 ft. long were set up on the inside of the lock in line, 6 ft. 7 ins. apart; and a similar row of posts 12 ft. long was set up outside of the lock. The posts were capped with 6 × 8-in. caps which supported the track stringers for the concrete cars. Each line of posts was sheeted with 3 × 10-in. plank dressed on all sides, and the posts were well braced with inclined struts. After the first lift was completed, the back row of posts was lifted onto the offset on the back of the wall by the reduced width of the next lift; but the long posts on the front face were not moved, the caps being simply unbolted from them and fastened near the top of the posts. The sheeting plank was of course moved up. No tie bolts were built into the concrete wall, which made the bracing of the forms rather elaborate as the wall grew higher.

The bottom-dump concrete cars were dumped onto wooden platforms inside the forms, as it was found that even a slight drop caused the larger stones to separate and roll to the outer edges. These stones were shoveled back into the pile, and then the concrete was placed with shovels. The doors of the cars were hung at the sides, and upon dumping they would strike the stringers carrying the track, thus jarring the forms and frequently throwing them out of line. A better method would have been to have hinged the doors at each end of the car. It was found advisable to have plenty of head room at the end of each lift, otherwise the spreading and ramming were not properly done. During the year ending June, 1895, there were only 30 days when work was carried on uninterrupted by floods. The total quantity of concrete placed that year was 8,710 cu. yds., the work being done by day laborers for the Government (not by contract). Negroes at \$1 per 8-hr. day were employed. The cost per cubic yard of 1:2:5½ concrete was as follows:

1 bbl. cement.....	\$2.48
0.88 cu. yd. stone, at \$0.76.....	.67
0.26 cu. yd. sand at \$0.34.....	.13
Mixing, placing and ramming.....	.88
Staging and forms.....	.42
Total, per cu. yd.....	\$4.57

Had wages been \$1.50 per day the cost would have been \$1.32 per cu. yd. instead of 88 cts. for mixing.

Cost of Locks, Cascade Canal.—In Gillette and Hill's "Concrete Construction," Chapter XI, on "Fortifications, Locks, Dams and Breakwaters," the methods of building and detailed costs are given. It will suffice here to state that the cost was \$8 per cu. yd. for machine mixed concrete, and \$9 for hand mixed concrete, of which cost \$5.50 was for materials, and \$1.70 for plant and superintendence.

Cost of Locks, Ill. and Miss. Canal.—In Gillette and Hill's "Concrete Construction," pp. 196 to 197; a detailed illustrated description is given of the forms, plant, and methods of building these locks. The cost of two of the locks was \$9 per cu. yd., of which \$2 to \$2.40 was labor and carpenter work. Cube mixers were used. For detailed costs consult the above reference.

Labor Cost of Retaining Walls.—In canal excavation, in subway work in cities, and the like, it is often necessary to dig trenches and build retaining walls in the trenches before excavating the core of earth between the walls. The following example of this class of work is taken from some records that I have: A Smith mixer was used, the concrete being delivered where wanted by a Lambert cableway of 400 ft. span. The broken stone and sand were delivered near the work in hopper-bottom cars which were dumped through a trestle onto a plank floor. Men loaded the material into one-horse dump carts which hauled it 300 ft. to the mixer platform. This platform was 24 X 24 ft. square, and 5 ft. high, with a planked approach 40 ft. long and contained 7,500 ft. B. M. The stone and sand were dumped at the mouth of the mixer and shoveled in by 4 men. Eight men, working in pairs, loaded the broken stone into the carts, and 2 men loaded the sand. Each cart was loaded with about 70 shovelfuls of stone on top of which 35 shovelfuls of sand were thrown. It took 3 to 5 mins. to load on the stone and 1 min. to load the sand. The carts traveled very slowly, about 150 ft. a minute—in fact, all the men on the job, including the cart drivers, were slow. After mixing, the concrete was dumped into iron buckets holding 14 cu. ft. water measure, making about $\frac{1}{2}$ cu. yd. in a batch. The buckets were hooked on to the cableway and conveyed where wanted in the wall. Steam for running the mixer was taken from the same boiler that supplied the cableway engine. The average output of this plant was 100 cu. yds. of concrete per 10-hr. day, although on many days the output was 125 cu. yds., or 250 batches. The cost of mixing and placing was as follows, on a basis of 100 cu. yds. per day:

	Per day.	Per cu. yd.
8 men loading stone into carts.....	\$ 12.00	\$.12
2 men loading sand into carts.....	3 00	.03
1 cart hauling cement.....	3.00	.03
3 carts hauling stone and sand.....	24.00	.24
4 men loading mixer.....	6.00	.06
1 man dumping mixer.....	1.50	.01
2 men handling buckets at mixer.....	3.00	.03
6 men dumping buckets and ramming	9 00	.09
12 men making forms at \$2.50.....	30.00	.30

1 cable engineman.....	3.00	.03
1 fireman	2.00	.03
1 foreman.....	6.00	.06
1 water-boy.....	1.00	.01
1 ton coal for cableway and mixer...	4.00	.04
Total	\$107.50	\$1.07

In addition to this cost of \$1.07 per cu. yd. there was the cost of moving the whole plant for every 350 ft. of wall. This required 2 days, at a cost of \$100, and as there were about 1,000 cu. yds. of concrete in 350 ft. of wall 16 ft. high, the cost of moving the plant was 10 cts. per cu. yd. of concrete, bringing the total cost of mixing and placing up to 87 cts. per cu. yd. As above stated, the whole gang was slow.

The labor cost of making the forms was high, for such simple and heavy work, costing \$10 per M. of lumber placed each day. The forms were 2-in. sheeting plank held by 4 X 6-in. upright studs 2½ ft. apart, which were braced against the sides of the trench. The face of the forms was dressed lumber and all cracks were carefully puttied and sandpapered.

The above costs relate only to the massive part of the wall and not the cost of putting in the facing mortar, which was excessively high. The face mortar was 2 ins. thick, and about 3½ cu. yds. of it were placed each day with a force of 8 men! Two of these men mixed the mortar, 3 men wheeled it in barrows to the wall, 3 men lowered it in buckets, and 2 men put it in place on the face of the wall. If we distribute this labor cost on the face mortar over the 100 cu. yds. of concrete laid each day, we have another 12 cts. per cu. yd.; but a better way is to regard this work as a separate item, and estimate it as square feet of facing work. In that case these 8 men did 500 sq. ft. of facing work per day at a cost of nearly 2½ cts. per sq. ft. for labor.

The building of a wall similar to the one just described was done by another gang as follows: The stone and sand were delivered in flat cars provided with side boards. In a stone car 6 men were kept busy shoveling stone into iron dump buckets having a capacity of 20 cu. ft. water measure. Each bucket was filled about two-thirds full of stone, then it was picked up by a derrick and swung over to the next car which contained sand, where two men filled the remaining third of the bucket with sand. The bucket was then lifted and swung by the derrick over to the platform of the mixer where it was dumped and its contents shoveled by four men into the mixer, cement being added by these men. The mixer was dumped by two men, loading iron buckets holding about ½ cu. yd. of concrete each, which was the size of each batch. A second derrick picked up the concrete bucket and swung it over to a platform where it was dumped by one man; then ten men loaded the concrete into wheelbarrows and wheeled it along a runway to the wall. One man assisted each barrow in dumping into a hopper on the top of a sheet-iron pipe which delivered the concrete. The two derricks were stiff-leg derricks with 40-ft. booms, provided

with bull-wheels, and operated by double cylinder (7 × 10-in.) engines of 18 hp. each. About 1 ton of coal was burned daily under the boiler supplying steam to these two hoisting engines. The output of this plant was 200 batches or 100 cu. yds. of concrete per 10-hr. day, when materials were promptly supplied by the railroad; but delays in delivering cars ran the average output down to 80 cu. yds. per day.

On the basis of 100 cu. yds. daily output, the cost of mixing and placing the concrete was as follows:

	Per day.	Per cu. yd.
5 men loading stone.....	\$ 7.50	\$0.07 1/2
2 men loading sand.....	3.00	.03
4 men charging mixer.....	8.00	.06
2 men loading concrete into buckets...	3.00	.03
1 man dumping concrete from buckets..	1.50	.01 1/2
10 men loading and wheeling concrete..	15.00	.15
1 man dumping wheelbarrows.....	1.50	.01 1/2
3 men spreading and ramming.....	4.50	.04 1/2
2 enginemen.....	5.00	.05
1 fireman.....	2.00	.02
1 water-boy.....	1.00	.01
1 foreman.....	6.00	.06
10 men making forms.....	25.00	.25
1 ton coal.....	4.00	.04
Total	\$85.00	\$0.85

In addition there were 8 men engaged in mixing and placing the 2-in. facing of mortar as stated above.

Cost of Retaining Walls, Chicago Drainage Canal.—Mr. James W. Beardsley gives the following data on 20,000 lin. ft. of concrete wall, built by contract. The work was let in two sections, Secs. 14 and 15, which will be considered separately. In both cases a 1.1 1/2 : 4 natural cement concrete was used, and it was faced with 1 : 3 Portland mortar 3 ins. thick, also coped with the same 3 ins. thick. The average height of the wall was 10 ft. on Sec. 14, and 22 ft. on Sec. 15, the thickness at the base being half the height.

On Sec. 14, the stone for the concrete was obtained from the spoil bank of the canal, loaded into wheelbarrows and wheeled about 100 ft. to the crusher; some was hauled in wagons. An Austin jaw crusher was used, and it discharged the stone into bins from which it was fed into a Sooy Smith mixer. The crusher and the mixer were mounted on a flat car. Bucket elevators were used to raise the stone, sand and cement from their bins to the mixer; the buckets were made of such size as to give the proper proportions of ingredients, as they all traveled at the same speed. Only two laborers were required to look after the elevators. The sand and cement were hauled by teams and dumped into the receiving bins. There were 22,568 cu. yds. on Sec. 14, and the cost was as follows:

General force.	Typical force.	Wages per 10 hrs.	Cost per cu. yd.
Superintendent	1.0	\$5.00	\$0.026
Blacksmith	1.1	2.75	0.016
Timekeeper	0.5	2.50	0.007
Watchman	0.6	2.00	0.007
Waterboys	3.9	1.00	0.022

Wall force.			
Foreman	0.9	3.50	0.013
Laborers	3.6	1.50	0.073

Teams	6.3	3.25	0.116
Crushing force.			
Foreman	0.5	\$2.50	\$0.007
Engineman	1.7	2.50	0.023
Laborers	3.5	1.50	0.032
Austin crushers.....	1.7	1.20	0.011
Loading stone.			
Foreman	1.7	3.50	0.023
Laborers	32.9	1.50	0.280

Total for crushing, mixing and placing.....\$0.975

The daily costs charged to the mixers and crushers include the cost of coal, at \$2 a ton, and the cost of oil.

The gang "loading stone" apparently did a good deal of sledging of large stones, and they also wheeled a large part of it in barrows to the crusher.

The plant cost \$9,600, distributed as follows:

2 jaw crushers.....	\$2,000
2 mixers.....	2,000
Track	1,260
Lumber	500
Pipe	840
Sheds	400
Pumps	600
Total	\$9,600

If this first cost of the plant were distributed over the 23,658 cu. yds. of concrete it would amount to 41 cts. per cu. yd.

The cost of the concrete was as follows:

	Per cu. yd.
Utica cement, at \$0.65 per bbl.....	\$0.863
Portland cement, at \$2.25 per bbl.....	0.305
Sand, at \$1.35 per cu. yd.....	0.465
Stone and labor, as above given.....	0.975
Total	\$2.608
First cost of plant.....	\$0.407

On Sec. 15 the conditions were much the same as on Sec. 14, just described, except that the limestone was quarried from the bed of the canal, and was crushed in a stationary crusher, No. 7 Gates. The stone was hauled 1,000 ft. to the crusher on cars drawn by a

cable from a hoisting engine. The output of this crusher averaged 210 cu. yds. per day of 10 hrs. The crushed stone was hauled in dump cars, drawn by a locomotive, to the mixers. Spiral screw mixers mounted on flat cars were used, and they delivered the concrete to belt conveyors which delivered the concrete into the forms.

The forms on Sec. 15 (and on Sec. 14 as well) consisted of upright posts set 8 ft. apart and 9 ins. in front of the wall, held at the toe by iron dowels driven into holes in the rock, and held to the rear posts by the rods. The plank sheeting was made up in panels 2 ft. wide and 16 ft. long, and was held up temporarily by loose rings which passed around the posts which were gripped by the friction of the rings. These panels were brought to proper line and held in place by wooden wedges. After the concrete had set 24 hrs. the wedges were struck, the panels removed and scraped clean ready to be used again.

The cost of quarrying and crushing the stone, and mixing the concrete on Sec. 15 was as follows:

General force.	Typical force.	Wages per 10 hrs.	Cost per cu. yd.
Superintendent	1.0	\$5.00	\$0.024
Blacksmith	0.9	3.75	0.011
Teams	1.7	3.00	0.025
Waterboy	4.5	1.00	0.022
Wall force.			
Foreman	1.1	2.50	0.010
Laborers	14.4	1.50	0.105
Tampers	0.1	1.75	0.001
Mixer force.			
Foreman	2.1	3.50	0.026
Enginemen	2.1	2.50	0.022
Laborers	23.1	1.50	0.180

Laborers	11.1	1.50	0.081
Firemen	1.0	1.75	0.008
Gyratory crusher	1.0	2.25	0.011
Quarry force.			
Foreman	1.2	2.50	0.012
Laborers	19.0	1.50	0.140
Drillers	1.8	2.00	0.017
Drill helpers	1.8	1.50	0.013
Machine drills	1.8	1.25	0.011
Total			\$0.593

The first cost of the plant for this work on Sec. 15 was \$25,420, distributed as follows:

1 crusher, No. 7 Gates.....	\$12,000
Use of locomotive.....	2,200
Cars and track.....	5,300
2 mixers.....	3,000
Lumber.....	1,200
Pipe.....	720
Small tools.....	1,000
Total	\$25,420

This \$25,420 distributed over the 44,811 cu. yds. of concrete amounts to 57 cts. per cu. yd.

It will be noted that 2 mixers were kept busy. Their average output was 100 cu. yds. each per day, which is the same as for the mixers on Sec. 14.

The total cost of concrete on Sec. 15 was as follows:

	Per cu. yd.
Labor quarrying, crushing and mixing.....	\$0.991
Explosives	0.083
Utica cement, at \$0.80 per bbl.....	0.920
Portland cement, at \$2.25 per bbl.....	0.180
Sand, at \$1.35 per cu. yd.....	0.476
Total	\$2.660
First cost of plant.....	\$0.567

It is not strictly correct to charge the full first cost of the plant to the work as it possessed considerable salvage value at the end.

For the purpose of comparing Secs. 14 and 15 the following summary is given of the cost per cubic yard of concrete:

	Sec. 14.	Sec. 15.
General force.....	\$0.078	\$0.082
Wall force.....	0.108	0.116
Mixing force.....	0.121	0.250
Timbering force.....	0.150	0.140
Hauling force.....	0.142	0.081
Crushing force.....	0.073	0.128
Quarry force.....	0.303	0.275
Cement, natural.....	0.863	0.920
Cement, Portland.....	0.305	0.180
Sand	0.465	0.476
Plant (full cost).....	0.407	0.567
Total	\$3.015	\$3.225

It should be remembered that on Sec. 14 there was no drilling and blasting of the rock, but that the "quarry force" not only loaded but hauled the stone to the crusher. The cost of mixing on Sec. 15 is higher than on Sec. 14 because the materials were dumped on platforms and shoveled into the mixer, instead of being discharged from bins into the mixer as on Sec. 14.

Cost of a Retaining Wall.—For building a retaining wall 7 ft. high, forms were made and placed by a carpenter and helper at \$2 per M. wages being 25 cts. and 20 cts. an hour, respectively. Concrete materials were dumped from wagons alongside the mixing board. Ramming was unusually thorough. Foreman expense was

high, due to small number in gang; 2 cu. yds. were laid per hour by the gang.

	Per day.	Per cu. yd.
7 mixers, 15 cts. per hr.....	\$10.50	\$0.53
3 rammers, 15 cts. per hr.....	3.00	0.15
1 foreman, 30 cts. per hr., and 1 water boy, 5 cts.....	3.50	0.17
Total labor.....	\$17.00	\$0.85

The total cost was as follows per cubic yard:

	Per cu. yd.
0.8 bbls. Portland cement, at \$2.....	\$1.60
Sand	0.30
Gravel	0.70
Labor mixing and placing.....	0.85
Lumber for forms, at \$16 per M.....	0.56
Labor on forms, at \$8 per M.....	0.28
Total, per cu. yd.....	\$4.29

The sheathing plank for the forms was 2-in. hemlock.

Cost of Retaining Walls, Reference.—Different methods of building walls, designs of forms, plant, etc., together with costs are given in "Concrete Construction," by Gillette and Hill.

Cost of Filling Pier Cylinders With Concrete.—In this case the gravel and sand forming the concrete were wheeled in barrows a distance of 100 ft. to the mixing-board at the foot of steel pier cylinders, into which concrete was dumped after raising it 20 ft. in wooden skips. Two cu. yds. concrete laid per hour by the gang.

	Per day.	Per cu. yd.
6 men wheeling materials and mixing, 15 cts. per hr.....	\$ 9.00	\$0.45
2 men dumping skips and ramming, 15 cts. per hr.....	3.00	0.15
1 team and driver, at 40 cts. per hr....	4.00	0.20
1 foreman, at 30 cts. per hr.....	3.00	0.15
Total	\$19.00	\$0.95

Had the job been larger, more men would have been employed to reduce the fixed expense of team time, for a team can readily raise 10 cu. yds. an hour, using a mast, or ginpole, with block and tackle. The foreman worked on the mixing-board himself. The concrete was perfectly mixed. The men worked with great energy.

Cost of Concrete Harbor Pier, Superior Entry, Wis.—For cuts showing cross-section of this pier, the forms used in its construction, and bucket used in depositing concrete under water, see Gillette and Hill's "Concrete Construction."

The pier is 2,023 ft. long at Superior Entry, Wis. The work was done by day labor for the Government, under the direction of Mr. Clarence Coleman, U. S. Assistant Engineer.

About 80% of the concrete was deposited in molds under water, according to a plan devised in 1902 by Maj. D. D. Gaillard, Corps of Engineers. The molds consisted of bottomless boxes, built in four pieces, two sides and two end pieces, held together by 1½-in. turn-buckle tie-rods. Cast-iron weights were attached to the molds to

overcome the buoyancy of the timber. The concrete was built in place, in two tiers of blocks, the lower tier resting directly on piles and entirely under water. The upper tier of blocks was almost entirely above water. A pile trestle was built on each side of the proposed pier, and a traveler for raising and lowering the molds, spanned the gap between the two trestles. After the mold for a block of concrete had been placed on the bottom, it was filled with concrete lowered in a bucket with a drop bottom. Twelve of these buckets were used, and were hauled from the mixer on cars to a locomotive crane, which lifted each bucket from the car and lowered it to place. The locomotive crane was elevated on a gantry frame so that a train of cars on the same trestle could pass directly under it without interference. This enabled two of these locomotive cranes to work on the same trestle.

Each concrete bucket was provided with two 12-oz. canvas curtains or covers each 3 X 4 ft., quilted with 110 pieces of 1/16 X 1 X 3-in. sheet-lead. The curtains were fastened, one to each side of the top of the bucket, and were folded over the concrete so as to cover it completely and protect it from wash while being lowered through the water. Occasionally, when an opportunity occurred to allow the top of the concrete in a bucket to be examined after being lowered and raised through 28 ft. of water, the concrete was invariably found in good condition. Discoloration of the water from cement was seldom noticed during the descent of the bucket. The concrete for this subaqueous work was mixed quite wet.

The pebbles for the concrete were delivered by contract, and were unloaded from the scows by means of a clam-shell bucket into a hopper. This hopper fed the pebbles on to an endless conveyor which delivered them to a rotary screen. Inside this screen water was discharged under a pressure from a 4-in. pipe, to wash the pebbles. From the screen the pebbles passed through a chute into 4-yd. cars, which were hauled up an incline to a height of 65 ft. by means of a hoisting engine. The cars were dumped automatically, forming a stock pile. Under the stock pile was a double gallery or tunnel, provided with eight chutes through the roof; and from these chutes the cars were loaded and hauled by a hoisting engine up an inclined trestle to the bins above the concrete mixer. A system of electric bell signals was used in handling these cars.

The sand was handled from the stock pile in the same manner. The cement was loaded in bags on a car at the warehouse, hauled to the mixer and elevated by a sprocket-chain elevator.

Chutes from the bins delivered the materials into the concrete mixer which was of the modified cubical type revolving on trunnions about an axial line through diagonal corners of the cube (made by the Municipal Engineering and Contracting Co., Chicago, Ill.). It was driven by a 7 X 10-in. vertical single engine with beiler. The mixer demonstrated its ability to turn out a batch of perfectly mixed concrete every 1½ mins. It discharged into a hopper, provided with a cut-off chute, which discharged into the concrete

buckets on the cars. Four buckets of concrete were hauled in a train by a locomotive to their destination. There were two locomotives and 23 cars.

In the operation of this plant 55 men were employed, 48 being engaged on actual concrete work and 13 building molds and appliances for future work. The work was done by day labor for the Government, and the cost of operation was as follows for one typical week when, in 6 days of 8 hours each, the output was 1,383 cu. yds., or an average of 230 cu. yds. per day. The output on one day was considerably below the average on account of an accident to plant but this may be considered as typical.

Pebbles from stock pile to mixer.	Per cu. yd.

Total per cu. yd.....	\$0.4473
Add 75% of the cost of administration.....	0.1388
Total labor per cu. yd.....	\$0.5861

The total cost of each cubic yard of concrete in place is estimated to be as follows:

	Per cu. yd.
Ten-eleventh cu. yd. pebbles, at \$1.086.....	\$0.9864
Ten-twenty-seconds cu. yd. sand, at \$0.00.....	0.0000
1.26 bbls. cement, at \$1.77.....	2.2302
Labor, as above given.....	0.5861
Cost of plant distributed over total average, ...	0.8400
Total yardage	\$4.6427

It will be noticed that the sand cost nothing, as it was dredged from the trench in which the pier was built, and paid for as dredging. The cost of the plant was distributed over the South Pier work and over the proposed North Pier work, on the basis of only 20% salvage value after the completion of both piers. It is said, however, that 80% is too high an allowance for the probable depreciation.

The cost of the trestles was included in the cost of the plant. The Washington fir used in the trestles cost \$16 per M. delivered in the yard. The cost of framing and placing the timberwork (exclusive of the piles) was \$3.25 per M.

The cost of the plant was as follows:

Machinery	\$30,055.98
Piles and pile driving.....	18,963.00
Lumber for trestles and molds.....	12,094.26
Iron and castings.....	7,572.38
Labor on plant.....	15,760.40
Total	\$79,446.00

The item of "labor on plant" includes all work in building trestles, laying track, building molds, mold traveler and all appurtenances for performing the work. The cost of plant per cu. yd. of concrete was estimated thus:

First cost.....	\$79,446
20% depreciation during use on South Pier....	15,889
Estimated increase in size of plant for use on North Pier.....	3,972
Total for both piers.....	\$99,307
Salvage value of plant 20%.....	19,861
Net	\$79,446
\$79,446 ÷ 94,000 cu. yds. = \$0.84 per cu. yd.	

The proportions of the subaqueous concrete were 1:2.5:5 by volume, or 1:2.73:6.78 by weight, cement being assumed to weigh 100 lbs. per cu. ft. The proportions of the superaqueous concrete were 1:3.12:8.25 by volume, or 1:3.41:7.22 by weight. The dry sand weighed 109.2 lbs. per cu. ft., the voids being 35.1%. The pebbles weighed 115.5 lbs. per cu. ft., the voids being 31%.

As above stated, the molds were bottomless boxes built in four pieces, two sides and two ends, held together by tie-rods. The 1½-in. turnbuckle tie-rods passed through the ends of beams that bore against the outside of the mold. These tie-rods had eyes at each end, in which rods with wedge shaped ends were inserted. The mold was erected on the trestle by the locomotive crane, and

was then lifted by the mold traveler, carried and lowered to place. The largest one of these molds, with its cast-iron ballast, weighed 40 tons. When it was desired to remove a mold, after the concrete block had hardened, the nuts on the wedge-ended rods were turned, thus pulling the wedge end from the eye of the tie-rod, and releasing the sides of the mold from the ends. The locomotive crane then raised the sides and ends separately and assembled them ready to be lowered again for the next block. The time required to remove one of these 40-ton molds, reassemble and set it again rarely exceeded 60 mins., and had been accomplished in 45 mins.

As already stated, the concrete was built in alternate blocks; then the intermediate blocks were built, the ends of the concrete blocks just built serving as end molds for the new blocks. The two sides of the mold (without the end pieces) were assembled by the aid of templates, and were bolted together by tie-rods. To hold the sides apart when the templates were removed, it was necessary to surround each of the six tie-rods with a box of 1-in. plank. These boxes measured 4 ins. square on the inside; and were left buried in the concrete. Their purpose was to act as horizontal struts to hold the sides of the mold apart, and to permit removal of the tie-rods after the concrete block had been built. The removal of these rods was accomplished by withdrawing the wedge-ended rods.

The mold traveler deserves a brief description. It was provided with a four-drum engine, and the drums were actuated by a worm gear which was positive in its movement in lowering as well as in raising. The drums act independently or together, as desired. The hoisting speed was 8 ft. per min., and the traveling speed, 100 ft. per min. The load was suspended on four hooks, depending by double blocks and $\frac{5}{8}$ -in. wire ropes from four trolleys suspended from the truss, which allowed lateral adjustment of the mold. The difficulty of using so broad a gage as 31 ft., on a curve having a radius of 543 ft., was overcome by using a differential gear in the driving shaft of the propelling gear, thus compensating for the greater distance traveled by the wheels on the outer rail. The whole machine was carried on six trucks having two double-flanged wheels each. The four forward trucks were swiveled on steel bed plates with 3-in. king bolts. The two rear trucks were fixed to the chord and had idler wheels, which slid on their axles so as to accommodate themselves to the curve.

Rubble Concrete Data.—By some engineers it is believed that rubble concrete, particularly for dam construction, is a very new form of masonry. In *Trans. Am. Soc. C. E.*, 1875, Mr. J. J. R. Cross describes work on the Boyd's Corner Dam on the Croton River, near New York. This work was begun in 1867, and for a time rubble concrete was used, but was finally discontinued, due to the impression that it might not be water-tight. In those days "sloppy" concrete would not have been allowed, which probably accounts for the difficulty of getting a water-tight rubble concrete. The specifications called for a dry concrete that had to be thoroughly rammed in between the rubble stones; and, to give room for this ramming, the

contractor was not permitted to lay any two stones closer together than 12 ins. As a result, not more than 33% of the masonry was rubble stones, the rest being the concrete between the stones. Mr. Cross states that most of the bidders erred in assuming that 66% to 75% of the masonry would be rubble stones.

The form of the rubble stones as they come from the quarry should be considered. Stones that have flat beds, like many sandstones and limestones, can be laid upon layers of "dry" concrete; and can have their vertical joints readily filled with concrete rammed into place. But granites and other stones that break out irregularly, can not be well bedded in concrete unless it is made so soft as to be "sloppy." In thin retaining walls, small, irregular stones may be forced into concrete by jumping upon them, men wearing rubber boots.

When stones come out flat bedded, if it is desired to economize cement, make the bed joints of ordinary mortar (not concrete) and fill the vertical joints with concrete.

Generally it is an absurd practice to break up large blocks of stone in a crusher for the purpose of making the whole of a heavy wall of concrete, since rubble concrete requires not only less cement but effects a saving in crushing. There are exceptions, however. For example, the anchorages of the Manhattan Bridge in New York City were specified to be of rubble concrete, doubtless because the designer believed this sort of masonry to be cheaper than concrete. In this case an economic mistake was made, for all the rubble stone must be quarried up the Hudson River, loaded into scows, unloaded onto cars, and finally unloaded and delivered by derricks. This repeated handling of large, irregular rubble stones is so expensive that it more than offsets the cost of crushing, as well as the extra cost of cement in plain concrete. Crushed stone can be unloaded from boats by means of clam-shell buckets at a low cost (see data in the section on Rock Excavation). It can be transported on a belt conveyor, elevated in a bucket conveyor, mixed with sand and cement, and delivered to the work, all with very little manual labor where the installation of a very efficient plant is justified by the magnitude of the job. Large rubble stones, on the other hand, can not be handled so cheaply nor with as great rapidity as crushed stone. Each particular piece of work, therefore, must be treated as a separate problem in engineering economics: for no unqualified generalization as to the relative cheapness of this or that kind of masonry is to be relied upon.

In the construction of a dry dock at the Charleston Navy Yard, rubble concrete was used. The rubble stones averaged about $\frac{1}{2}$ cu. yd. each, and were spaced about 18 ins. apart. About 67% of the masonry was 1:2:5 concrete, leaving 33% of rubble stones.

The Spier Falls Dam on the upper Hudson River is of cyclopean masonry, the rubble stones being very large pieces of granite, which are bedded in 1:2 $\frac{1}{2}$:5 concrete. At the time of my visit to the dam, it was estimated that about 33% of the masonry was

concrete, I have recently been informed by Mr. C. E. Parsons, the chief engineer, that about 1 bbl. of cement was used in each cubic yard of masonry. This high percentage of cement may be accounted for by the fact that there was a good deal of plain rubble laid in 1:3 cement mortar, no accurate record of which was kept. At the time of my visit, three Ransome mixers were being used, two for concrete and one for mortar. Each concrete mixer averaged 200 batches in 10 hrs., of 28 cu. ft. of concrete per batch. I am inclined to think, from inspection of the masonry during the time it was being laid, that about 40% of the dam was rubble stones and the remaining 60% was concrete and mortar. The stones and concrete were delivered by cableways to stiff-leg derricks, which deposited the material in the dam. There were two laborers to each mason employed in placing the materials, wages being 15 cts. and 35 cts. per hr. respectively. The labor cost of placing the materials was 60 cts. per cu. yd. of masonry. Mr. Parsons states that the 155,000 cu. yds. of cyclopean masonry actually cost \$5.71 per cu. yd., exclusive of the plant depreciation, and that calling the plant depreciation 40% of its first cost, it would add 10% to the cost of the masonry, or 57 cts. per cu. yd., making a total of \$6.28 per cu. yd. This does not include the cofferdam.

For a rubble concrete dam across the Chattahoochee, 17 miles north of Atlanta, Ga., the stone was a local gneiss that came out of the quarry in large slabs with parallel beds, some stones containing 4 cu. yds. each. About 40% of the dam was of this rubble and 60% of concrete between the rubble stones. The concrete was a 1:2½:5 mixture.

The breakwater at Marquette, Mich., was built of rubble concrete, the rubble stones amounting to 27% of the volume of the breakwater masonry.

The Hemet Dam, California, is built of granite rubble concrete, the concrete being a 1:3:6 mixture. The face stones of the dam were laid in mortar. There were 31,100 cu. yds. of masonry, which required 20,000 bbls. of cement, or 0.64 bbl. per cu. yd. The cement was hauled 23 miles over roads having grades of 18% in places, the total ascent being 3,350 ft. The cost of hauling was \$1 to \$1.50 per bbl. The sand was conveyed 400 ft. from the river to the dam by an endless double-rope carrier provided with V-shaped buckets spaced 20 ft. apart, the rise of the conveyor being 125 ft. in the 400 ft. This was a simple and inexpensive conveyor.

The Boonton Dam, Boonton, N. J., is of cyclopean masonry, that is, of large rubble stones bedded in concrete. The concrete was made so wet that when the stones were dropped into it the concrete flowed into every crevice. The granite rubble stones measured from 1 to 2½ cu. yds. each. The materials were all delivered on cars, from which they were delivered to the dam by derricks provided with bull-wheels. On the dam were 4 laborers and 1 mason to each derrick, and this gang dumped concrete and joggled the rubble stones into it. A derrick has laid as much as 125 cu. yds. of masonry in 10 hrs.

With 35 derricks, 20 of which were laying masonry and 15 either passing materials to the other derricks, or being moved, as much as 21,000 cu. yds. of masonry were laid in one month. The amount of cement per cubic yard of masonry was 0.68 bbl., the cyclopean stone occupying 45 to 50% of the volume of the dam.

Cost of the Boonton Dam, Cyclopean Masonry.—In the preceding paragraph the character of this masonry is given. Mr. E. L. Harrison informs me that the rock was syenitic granite, "not quite so hard to quarry as trap rock." About 50% was concrete, mixed 1:2, and 0.68 bbl. cement was required per cu. yd. of the masonry, at \$1.50 per bbl. Wages of common laborers were \$1.55 per 10-hr. day, and the cost to the contractor would have been \$4 per cu. yd. had he furnished the cement.

Mr. J. Waldo Smith has stated that 45% of the dam was cyclopean stone and that the cost to the contractor was \$3.23 per cu. yd. exclusive of cement. If we add \$1.05 for cement, we have \$4.28 per cu. yd.

Some English Data on Rubble Concrete.—The following is an abstract of an article from London "Engineering": Railway work, under Mr. John Strain, in Scotland and Spain, involved the building of abutments, piers and arches of rubble concrete. The concrete was made of 1 part cement to 5 parts of ballast, the ballast consisting of broken stone or slag and sand mixed in proportions determined by experiment. The materials were mixed by turning with shovels 4 times dry, then 4 times more during the addition of water through a rose nozzle. A bed of concrete 6 ins. thick was first laid, and on this a layer of rubble stones, no two stones being nearer together than 3 ins., nor nearer the forms than 3 ins. The stones were rammed and probed around with a trowel to leave no spaces. Over each layer of rubble, concrete was spread to a depth of 6 ins. The forms or molds for piers for a viaduct were simply large open boxes, the four sides of which could be taken apart. The depth of the boxes was uniform, and they were numbered from the top down, so that, knowing the height of a given pier, the proper box for the base could be selected. As each box was filled, the next one smaller in size was swung into place with a derrick. The following bridge piers for the Tharst & Calanas Ry. were built:

Name.	Length of Bridge. Ft.	Height of Piers. Ft.	No. of Spans.	Cu. Yds. in Piers.	Weeks to Build.
Tamujoso River.....	435	28	12	1,737	14½
Oraque	423	31	11	1,590	16
Cascabelero	480	30 to 30	10	2,880	21
No. 16.....	294	28 to 50	7	1,046	16½
Tiesa	165	16 to 23	8	420	4

It is stated that the construction of some of these piers in ordinary masonry would have taken four times as long. The rock available for rubble did not yield large blocks, consequently the percentage of pure concrete in the piers was large, averaging 70%. In one case, where the stones were smaller than usual, the percentage

of concrete was 76½%. In other work the percentage has been as low as 55%, and in still other work where a rubble face work was used the percentage of concrete has been 40%.

In these piers the average quantities of materials per cubic yard of rubble concrete were:

448 lbs. (0.178 cu. yd.) cement.

0.86 cu. yd. sand.

6.63 cu. yd. broken stone (measured loose in piles).

6.30 cu. yd. rubble (measured solid).

Several railway bridge piers and abutments in Scotland are cited. In one of these, large rubble stones of irregular size and weighing 2 tons each were set inside the forms, 8 ins. away from the plank and 3 ins. from one another. The gang to each derrick was: 1 derrickman and 1 boy, 1 mason and 10 laborers, and about one-quarter of the time of 1 carpenter and his helper raising the forms. For bridges of 400 cu. yds., the progress was 12 to 15 cu. yds. per day. The forms were left in place 10 days.

To chip off a few inches from the face of a concrete abutment that was too far out, required the work of 1 quarryman 5 days per cu. yd. of solid concrete chipped off.

Concrete was used for a skew arch over the River Dochart, on the Kilmn Ry., Scotland. There were 5 arches, each of 30 ft. span on the square or 42 ft. on the skew, the skew being 45°. The piers were of rubble concrete. The concrete in the arch was wheeled 300 ft. on a trestle, and dumped onto the centers. It was rammed in 6-in. layers, which were laid corresponding to the courses of arch stones. As the layers approached the crown of the arch, some difficulty was experienced in keeping the surfaces perpendicular. Each arch was completed in a day.

In a paper by John W. Steven, in Proc. Inst. C. E., the following is given:

	Concrete per cu. yd.	Rubble Concrete per cu. yd.	Per Cent of Rubble in Rubble Concrete.
Ardrossan Harbor.....	\$6.00	\$5.00	20.0
Irvine Branch.....	7.00	3.68	63.6
Calanas & Tharsis Ry.....	7.68	3.43	30.8

Cost of a Rubble Concrete Abutment.—Mr. Emmet Steece gives the cost of 278 cu. yds. rubble concrete in a bridge abutment at Burlington, Ia., as follows:

	Per cu. yd.
0.52 bbl. Saylor's Portland at \$2.60.....	\$2.14
0.22 cu. yd. sand, at \$1.....	0.22
0.53 cu. yd. broken stone, at \$0.94.....	0.49
0.38 cu. yd. rubble stones, at \$0.63.....	0.24
Water.....	0.07
Labor (15 cts. per hr.).....	1.19
Foreman.....	0.09
Total.....	\$4.44

The concrete was 1:2½:4½, laid in 4-in. layers, on which were laid large rubble stones spaced about 6 ins. apart. Concrete was rammed into the spaces between the rubble, which was then covered with another 4-in. layer of concrete, and so on. A force of 28 men and a foreman averaged nearly 40 cu. yds. of rubble concrete per day. The cost of lumber for the forms is not included. The abutment was 3 ft. wide at top, 9 ft. at the base and 30 ft. high.

Cost of a Rubble Concrete Dam in the Central States.*—This article describes the earthwork and concrete construction incident to a hydro-electric development in the middle West. Although neither the name of the contractor nor the locality of the work can be given, it will serve all statistical purposes to state that the work was located within 200 miles of Chicago in a small country town, whose population was made up almost entirely of those employed on the construction, but one whose railroad facilities were all that could be desired. The river is one of the upper tributaries of the Mississippi, draining over 1,200 square miles of densely wooded forest land, flowing through a series of broad marshes and swift rapids, deep cut in the narrow valleys, until it empties into the mother stream. At the chosen site there is an average depth of 6 ft. and flow of 600 cu. ft. per second, which will impound a reservoir with an area of 650 acres and a maximum depth of 50 ft., 10 ft. of which is available, as the river here narrows down from a wide marsh plain to a deep rocky channel, making an ideal spot for water storage.

The dam is a structure of cyclopean masonry, having a spillway of 490 ft. flanked on each side by abutments of the same material and earth dikes extending 1,500 and 2,800 ft. from each end. The dam itself has a maximum height of 49 ft. and a width of base of 49 ft., its section being of a standard "ogee" type. The earth dikes have an extreme height of 31 ft., side slopes of 2 to 1, 4-ft. berm, and are made impervious by concrete core walls founded on bedrock. These have a thickness of 2 ft. at the top and a batter of 12 on 1 on each side.

The preliminary construction work, consisting of the erection of a camp for the working force of 400 men and the clearing of the dam site, was commenced April 10, but it was not until the following June that the organization was complete and the work well under way, the first concrete being laid July 9. The actual work of harnessing the river was accomplished by building above the dam location a timber rock-filled cofferdam, 500 x 150 ft., with a maximum height of 16 ft., the natural bank forming one side, thereby diverting the water into the east half of the river channel and allowing the excavation to be carried in the dry to bedrock.

Concrete mixing plants were erected on each side of the river, containing three No. 4 Ransome mixers. An excellent granite quarry was opened up on the east side of the river, where a crushing plant

**Engineering-Contracting*, Oct. 7 1908.

of considerable capacity was erected, the broken stone being carried from there to the bins of the mixing plants by construction trains of Western dump cars. Sand and gravel were obtained from a nearby borrow pit with drag scrapers, screened and brought to the bins in dump-car trains. Cement was kept in an adjacent storehouse and wheeled by hand to chutes immediately above the mixers.

The mixture was in 1 cu. yd. batches in the proportions of 1:2½:5, using Atlas Portland cement. About 150 cu. yds. is the average daily output of each mixer. The concrete was delivered in 1 cu. yd. tipping buckets and placed in the forms by means of push cars and 5-ton, 80-ft. boom, guyed derricks, operated by Lidgerwood and American double-drum engines, which were the limiting factors in the daily progress. Plum stones up to 1 cu. yd. in volume were bedded in the concrete and formed about 25% of its mass. Lifts of 3 to 8 ft. a day were secured, care being taken in filling the forms to complete a horizontal course over the whole surface. Successive lifts were bonded together by the use of large stones imbedded so as to project half way above the surface of the lower course and lock with the subsequent layer.

The forms were built of 2-in. dressed pine planks, braced with 4 x 6-in. studding, spaced 3 ft. apart on centers and stiffened with 6 x 8-in. horizontal waling pieces attached every 4 ft. The forms were anchored with heavy iron wire, or ¼-in. band iron, and were not interchangeable, being knocked down as each section was stripped, and rebuilt for the next.

The dam was constructed in alternate sections, 40 ft. long, bonded together with vertical keys, 3 ft. apart in the clear and terminating 2 ft. below the upper surface. Upon reaching the center, the end cofferdams were removed and rebuilt across the east channel, sending the water through five 10 x 10-ft. sluiceways left temporarily in the structure. The excavation was then pushed forward in the east channel, and on Dec. 3 the last bucket of concrete was placed in the closing sluices.

The earth dikes were filled by drag and wheel scrapers drawn by Missouri mules, the former being used for all hauls under 200 ft. The corewalls were first constructed on bedrock, the concrete being wheeled in barrows an average of 200 ft. from construction train to forms. Care was taken to bring no unnecessary stress on the walls by maintaining the fill at equal heights on each side of the core. Clay puddle and riprap protect the sides from erosion.

The plant and construction costs were as follows:

Camp.—The camp consisted of the following buildings:

	Floor Area, Sq. Ft.
8 dormitories for 283 men.....	15,000
2 mess halls for 80 men.....	3,000
3 individual shacks for 3 men.....	864
1 storehouse	1,136
1 machine shop.....	900
1 blacksmith shop.....	100
Total floor area.....	21,000

The cost of constructing these buildings was as follows:

Item.	Cost.
158,000 ft. B. M. of lumber at \$22.50.....	\$3,575
15 carpenters 48 days at \$3.....	2,160
30,000 sq. ft. tar paper at \$0.0225.....	675
Nails	145

Total 21,000 sq. ft. at \$0.31.....	\$6,555
Interest and depreciation.....	5,500

The cost per square foot of building was as follows:

	Per sq. ft.	Per cent.
Lumber	\$0.17	55
Labor	0.10	32
Roofing and hardware.....	0.14	13
Total	\$0.31	100

The carpenter work cost \$13.70 per 1,000 ft. B. M., which is a high cost.

Sand and Gravel.—The excavation and screening of the sand and gravel required the following plant: One screening plant, 6 wheel scrapers, 7 spans of mules and harnesses, 6 living tents, 2 mule tents, $\frac{1}{2}$ dinkey engine, 6 Western dump cars and $\frac{1}{2}$ mile of track. The investment cost of the plant was \$11,500; the daily plant charge was as follows for 165 days:

	Per day.
Interest and depreciation, \$5,000.....	\$30.30
Coal for boiler.....	2.00
Coal for $\frac{1}{2}$ dinkey.....	0.50
Oil for engine.....	0.40
Oil for $\frac{1}{2}$ dinkey.....	0.10
Feed and care of mules.....	7.50
Total	\$40.80

Broken Stone.—The plant for quarrying and crushing the broken stone was as follows: One No. 5 Austin crusher, 1 hoisting engine and boiler, 1 60-ft. derrick, 4 steam drills, 6 scale boxes, 1,200 ft. track, $\frac{3}{4}$ dinkey engine, 6 Western dump cars, 1 blacksmith's shop and 1 winch. The investment cost was \$13,000; the daily plant charges were as follows for 170 days:

	Per day.
Interest and depreciation, \$5,500.....	\$32.30
Coal for boilers.....	5.50
Coal for $\frac{3}{4}$ dinkey.....	1.00
Oil for engines.....	0.80
Oil for dinkey.....	0.20
Explosives	22.50
Total	\$61.80

Mixing.—The mixing plant consisted of 2 mixing plants (2 No. 4 Ransome mixers, 1 cu. yd. batch), 3 cement trucks, 700 ft. of track with trestle, 2 cement houses, 1 sand chute and 2 sand cars. The investment cost of the plant was \$7,900; the daily plant charges were as follows for 168 days:

Item.	Per day.
Interest and depreciation, \$2,900.....	\$17.30
Coal	2.10
Oil	0.15
Total, 180 cu. yds., at \$0.10.....	\$19.45

Placing.—The plant required for placing concrete was as follows: Six hoisting engines and boilers, 7 derricks, 9 tipping buckets, 800 ft. of track, 6 flat cars, 500 ft. of trestle, 1 dinky, 4 Western dump cars, 15 wheelbarrows and 18 shovels. The investment cost was \$18,000 and the daily plant charge was as follows:

Item.	Per day.
Interest and depreciation, \$5,600.....	\$21.75
Coal	5.00
Oil	1.00
Total, 180 cu. yds., at \$0.21.....	\$37.75

Wages.—The wages paid labor were as follows:

Class.	Per day.
Foremen	\$3.00 to \$5.00
Engineers	\$2.25 to \$3.50
Firemen	\$1.75 to \$2.75
Tagmen	\$2.00
Carpenters	\$2.00 to \$3.50
Rivermen	\$3.00
Electricians	\$2.00
Riggers	\$2.50 to \$3.50
Mechanics	\$2.75 to \$3.50
Cooks	\$2.00
Laborers	\$1.75 to \$2.25
Water boys	\$1.50

Main Dam and Concrete.—The cost in place of the 30,000 cu. yds. of rubble concrete in the main dam inclusive of labor and plant charges was as follows:

	Foremen.	Skilled Laborers.	Laborers.	Cost Per cu. yd.
Stone	3	8	8	\$1.28
Sand	1	3	10	0.48
Cement	2.31
Forms	3	25	1	0.62
Mixing	4	3	32	0.58
Placing	3	6	46	0.69
Total				\$5.92

Referring to the forms, the cost of material per foot board measure was:

	Per ft. B. M.
Lumber	\$0.022
Nails	0.001
Wire	0.005
Total	\$0.028

The forms were used three times and the average cost of forms per square foot of surface covered was 24 cts., which is a very high cost.

Concrete Corewall, East Dike.—This corewall averaged 11.2 ft. in height, contained 2,893 cu. yds., and took 78 days, including Sundays and idle days, to build with a force of 5 foremen, 10 skilled laborers and 80 laborers. Sectional forms 4 x 12 ft. of 1-in. boards and 2 x 6-in. studding, were used. The concrete was delivered to trestle running 1,000 ft. by train. The cost of the corewall was as follows:

Item.	Total.
3,350 bbla. cement, at \$2.31.....	\$ 6,676
964 cu. yds. sand and gravel, at 75 cts.....	726
1,928 cu. yds. broken stone, at \$1.08.....	2,082
Mixing concrete (2,983 cu. yds., at 42 cts.).....	1,215
Placing concrete (2,893 cu. yds., at \$1.01).....	2,947
22,400 sq. ft. forms, at 43 cts.....	1,382
Total	\$14,876
1,450 cu. yds. excavation, at 98 cts.....	1,424
Grand total	\$16,300

The cost per cubic yard of concrete work proper was thus \$5.14 and the cost including excavation was \$5.56 per cu. yd.

Earthwork.—The cost of the earthwork in the dikes was as follows:

East dike: Volume, 21,900 cu. yds., sandy loam; force, 2 foremen, 44 laborers, 60 mules; lead, 600 ft.; plant, No. 2 wheel scrapers; unit cost, 28 cts. per cu. yd.

West dike: 8,900 cu. yds., sandy loam; force, 1 foreman, 14 laborers, 20 mules, lead, 60 ft.; plant, drag scrapers; unit cost, 25 cts. per cu. yd.

Cost of Concrete Fence Post.—Mr. J. A. Mitchell gives the following:

Fence posts need not contain more than 0.6 cu. ft. of concrete, if the posts are made tapering. They should be reinforced with galvanized wire, for the metal is so close to the surface of the concrete that it is likely to rust. Two men will make 100 such posts per day, or 2.22 cu. yds.; while three good men have made 200 posts per day, or about 1.5 cu. yds. per man. A double mold for making two parts is used, and should be collapsible, so that it can be removed in 24 to 48 hrs. Wooden molds that have been in use three years are still in service. Such posts can be made for 11 to 12½ cts. each, which is equivalent to about \$5.40 per cu. yd., prices being as follows:

Cement, per bbl.....	\$1.50
Gravel, per cu. yd.....	0.40
Galvanized wire, per lb.....	.02%
Wages, per day.....	1.50
Mixtures of 1:3 and 1:4 are best.	

Cost of Reinforced Concrete Telephone Poles.*—The possibilities for reinforced concrete poles in transmission line work have recently been very carefully investigated by the Richmond (Ind.) Home Telephone Co., which has constructed a line across the White-water River, using poles ranging from 45 to 55 ft. in height of the construction shown by Fig. 2, invented by Mr. Wm. M. Bailey, Vice-President and General Manager of the company. The following account of these investigations and of the studies made by the American Concrete Pole Co., Richmond, Ind., which has been organized to market the poles, has been compiled from information given us by Mr. Bailey

For poles 30 ft. long and under, the molding is done horizontally

**Engineering-Contracting*, March 11, 1908.

on the ground and the pole erected when hard like a wooden pole; for poles over 30 ft. long the molding is done in forms set vertical in the pole hole. The following figures, Table IX, are given as the cost without royalty of concrete poles molded as described. These costs are for poles erected excluding the material cost of steps but in-

Fig. 2.—Concrete Telephone Pole.

cluding labor cost of setting steps, and they are based on the following wages and prices:

Foreman, per day.....	\$3.00
Laborers, per day.....	1.75
Cement, per barrel.....	2.00
Stone, gravel or sand, per cu. yd.....	1.00

For sake of comparison, the cost of cedar poles has been added to the table; these costs include poles, unloading, dressing, gaining, roofing, boring, hauling and setting. All figures are as furnished by Mr. Bailey. Regarding the methods of constructing concrete poles, Mr. Bailey says:

"All of the larger concrete poles (that is, poles over 30 ft. in height), are built upright in position ready for use, the forms being set perpendicularly over the hole in which the pole is to be placed, the hole having been dug to conform with the size pole prior to the setting of form; thus when the concrete is poured in at the top of form, the hole is entirely filled and the concrete knit firmly to the

TABLE IX.—COMPARATIVE COST OF REINFORCED CONCRETE AND CEDAR POLES.

solid earth that has never been disturbed. There is no replacing of earth or tamping required.

"All poles under 30 ft. in height, up to the present time, have been built on the ground and set after they have been seasoned, although there is some doubt in my mind and I believe that with the proper equipment and a little practice that it will be discovered that even the smaller poles can be built more economically upright. As to the cost of setting these poles, it is true that they will have to be handled with a derrick or gin pole, but with this equipment they can be handled very rapidly, and, I believe, almost as cheaply as the wooden pole. One can readily see that as the larger poles are built upright in position which they are to occupy, that there is no heavy material to handle—consequently, there will be no necessity for any heavy rigging or equipment. The hole is first dug and the form is set directly over the same. After the form has been placed, the reinforcing rods and binding wires are placed and the form is then ready to receive concrete. After the concrete has been poured in, it is left for about three or four days, depending on the weather, before the forms are removed. The most economical way of handling concrete is with a small mixer, capable of mixing 2 or 3 cu. yds. per hour and the old-fashioned grain elevator. With this equipment, the concrete is placed as rapidly as it is mixed and with the same power. The pouring in of the concrete into the top of the form tamps it thoroughly and it shows a solid compact concrete.

"This proposition is like a great many others—at first sight it appears impractical on account of first cost, but on investigation we find that this is only a phantom and that after all is done and said, the proposition is economy.

"I give you here the exact cost data on one of the 55-ft. poles erected over the Whitewater river at Richmond, Ind.:

Materials:	
4 1-in. steel rods 40 ft. long, and 4 $\frac{3}{4}$ -in. steel rods, 15 ft. long including "U" bolts with which they were tied together.....	\$12.34
56 cu. ft. of concrete.....	7.84
1 set of binding wires	1.80
Total materials	\$22.98
Labor:	
4 men setting form, placing rods, and binding wire, guying, truing same ready for concrete, one day:	
1 man, at \$3.00.....	\$ 3.00
1 man, at \$2.50.....	2.50
2 men, at \$2.00.....	4.00
4 men and one horse mixing and placing concrete, 2 hrs. and 11 mins.	2.28
2 men taking down form and touching up pole, 3 hrs.	1.35
Total labor	\$13.13
Total materials and labor.....	\$36.11

"You will note that this cost is \$4.18 in excess of my tabulated statement (Table I). This was due to the location of the lead.

These poles were set in over rough ground and in a river bottom where we had water to contend with and the conditions were very unfavorable to the erection of any kind of poles. It would have cost considerable more to set wood poles in the same place. We were also obliged to use labor inexperienced on this class of work. I believe that after the men are properly broken in and equipment working properly, that concrete poles can actually be built for less than first-class cedar complete, set in the ground. There is no comparison between wood and concrete when we take into consideration strength, durability, and its lack of destruction from other causes, such as birds, insects, lightning, etc. The more thought and test that the writer applies to this method of construction, the more enthusiastic he has become and he expects to see the day when no first-class construction will consider anything but steel, iron or concrete poles."

Cost of Reinforced Concrete Poles.*—Mr. F. J. Hunt is author of the following:

The prime factors in the construction of concrete poles are the materials forming the grout. This is true of all concrete construction, but particularly so in the construction of concrete poles, where the cross-section is small and the greatest possible tensile strength is desired. Unless the best quality of crushed stone and sand is used, desired results cannot be obtained. Fig. 3 shows the method of molding concrete poles on which these and the following remarks are based.

The steel reinforcing rods are placed 1 in. from the surface of the pole in 3 sets; four rods extend to the top of the pole, four rods two-thirds of the length of the pole and four rods one-third of the length. In testing the finished pole to destruction this distribution of the steel was found to be practical, giving a uniform stress from top to ground line. A 30-ft. pole with 6-in. top and 9-in. base deflected 3 ft. at the top from a plumb line, and straightened when the load was removed without any apparent damage to the pole. A 30-ft. pole must stand a strain of 2,500 ft. lbs., at the groundline. The feature to be reckoned with in the building of a line of concrete poles is the transportation and erection. A 30-ft. pole, with a 6-in. top, will weigh 2,000 lbs. It is a practical proposition to build this length pole in a yard, in forms on the ground. A pole of any greater length should be built in place, from the ground up, although I have erected 45-ft. poles that weighed 5,600 lbs. The 30-ft. reinforced concrete pole can be built in Chicago for \$7.50 and erected with proper equipment for \$1 each.

The reinforced 30-ft. concrete pole with 6-in. top and 10-in. base, and corners chamfered to 1-in. radii contains $\frac{1}{2}$ cu. yd. of concrete and 200 lbs. of steel, the cost being as follows:

200 lbs. of steel, at \$1.85 per 100 lbs.....	\$3.70
$\frac{1}{2}$ cu. yd. concrete, at \$7.50 per yd.....	2.75
Total	\$7.45

**Engineering-Contracting*, Feb. 26, 1908.

The estimate of the cost of the finished pole is based on the following prices: Crushed stone, \$1.25 per cu. yd.; sand, \$1.10 per cu. yd.; cement, \$1.75 per bbl., and labor, 20 cts. per hr. In erecting concrete poles, the equipment will vary to suit the conditions. On traction lines, where the poles are close to the track, the most convenient method of erection is to rig a hinged stiff-leg derrick on a flat car, with a boom of sufficient length to pick up poles on cars at

Fig. 3.—Molding Poles.

either end of the derrick car. This derrick should be hinged so as to be conveniently lowered to pass under grade-crossings and obstructions of any nature. On steam railway construction, where the pole line is often 60 to 70 ft. from the track, a derrick truck with jack-arms is used in the same manner as the car, picking up the delivered poles from the ground instead of from the car.

Bills of Materials and Cost of Concrete Poles.*—The increasing cost of wooden poles for telephone, telegraph, trolley line and other electric transmission line work is leading engineers seriously to search for some substitute material. This material is believed by a number of engineers to be reinforced concrete and within the last year or two there have been quite extensive studies of reinforced concrete pole construction. The results of some of these studies are given in the succeeding sections, and in connection with them the reader will do well to consult the article published in our issue of Nov. 20, 1907, describing the construction of 150-ft. transmission line

**Engineering-Contracting*, Jan. 20, 1908.

poles for the Lincoln Light & Power Co. in Ontario and giving the methods adopted for computing the stresses.

Comparative Strength Tests of Concrete and Cedar Poles.—In 1906 two forms of reinforced concrete poles were tested in comparison with two 30-ft. selected cedar poles for Mr. G. A. Cellar, Superintendent of Telegraph, Pennsylvania Lines west of Pittsburgh. The concrete poles were made and the tests conducted by Mr. Robert A. Cummings of Pittsburgh, Pa. Both poles were 8 ins. in diameter at the top and 13 ins. in diameter at the base and both poles were molded hollow, with shells from $1\frac{1}{4}$ ins. to 2 ins. thick, for about two-thirds of their height and solid for the rest of the height. One pole was octagonal in section and one was square in section with chamfered corners. Each pole weighed approximately 3,500 lbs. Both poles were designed to carry 50 wires each coated with ice enough to make it 1 in. in diameter, and to resist a wind load of 30 lbs. per sq. ft. The poles were assumed to stand 100 ft. apart and were made 30 ft. high. These conditions are approximately equivalent to a concentrated load of 1,000 lbs. applied near the top of the pole. The reinforcement for both poles consisted of a peripheral ring of eight 24-ft. bars of round steel and alternately $\frac{3}{4}$ in. and $\frac{1}{2}$ in. in diameter. Wooden blocks were molded into the poles for attaching clips and braces and through holes cored for cross-arm bolts. Both the wooden and the concrete poles were set approximately 5 ft. into 2 x 3 x 5 ft. concrete bases.

Mr. Cummings describes the method of conducting the tests as follows:

"The load was applied through a band 10 ins. from the top of the pole by means of two $\frac{1}{2}$ -in. wire ropes which passed over two 12-in. sheaves near the end of an inclined A-frame. These ropes received the hook supporting a differential chain hoist of 5 tons capacity. The base of the A-frame rested freely upon the front edge of the concrete foundation and inclined away from the poles at an angle of 45° . A pulley suspended from the extreme end of the A-frame carried the differential hoist, the lever arm and counterweight. The initial load applied at the top of the pole was thus reduced to 50 lbs. The total amount of applied load was measured by a simple lever. One end of which was supported on the platform of a 2,500-lb. capacity weighing scale, while the other end was attached to chain hoist. The two acted through a rocker fulcrum suitably supported. The load was applied or released by operating the differential hoist. In applying the load the hoist would reduce the distance between the hooks at any rate of speed desired. A graduated rule was fastened at the top of the pole being tested and extended back parallel with the line of poles crossing the arm containing a gage pin, from which point deflections were read. This arm was nailed to a rigidly braced upright erected near the rear telegraph pole. Deflections (Table X) were also read 12 ins. above the foundations by means of a movable rule. The platform for supporting the observer reading deflections at top of poles was suspended from a nearby bridge. The accompanying table gives the loads and corresponding deflections of four poles

tested. The white cedar poles broke about 7 ft. above the foundation. The concrete poles failed by crushing of the concrete in the base of poles at the level of the foundation."

Nashville, Chattanooga & St. Louis Ry.—Fig. 4 shows the standard reinforced concrete pole designed to support bridge warnings by Mr. Hunter McDonald, Chief Engineer, Nashville, Chattanooga & St. Louis Ry. Originally the pole was molded with pole, cross-arm and brace all of concrete and in one piece, but this was found too expensive and the gas pipe cross-arm and brace were substituted. One pole of each construction has been in use over three years. The one with the concrete cross-arm shows considerable bending, but the other does not. The bill of materials for the concrete pole shown by Fig. 4 is as follows:

Shaft: $\frac{1}{2}$ cu. yd. platform screenings, $\frac{1}{2}$ cu. yd. sand, and $2\frac{1}{2}$ bags Portland cement.

Base: $1\frac{1}{2}$ cu. yds. crushed stone, $\frac{1}{2}$ cu. yd. sand, and 6 bags Portland cement.

Fort Wayne & Wabash Valley Traction Co.—This company operating some 150 miles of street and interurban trolley line proposes to make its renewals with concrete poles of the construction shown by Figs. 6 to 8. Fig. 5 shows the 42-ft. pole complete and Figs. 6, 7 and 8 show, respectively, the 32 and 30-ft. pole reinforcement. The weight and dimensions of the pole and the bill of material required are given for each size. Regarding the construction of these poles Mr. H. L. Weber, Chief Engineer of the road, writes:

"The cost of constructing concrete poles depends so much upon the location of the materials with respect to the points where the poles are to be erected that general figures are difficult to state. Having several good gravel banks at convenient points along our right of way, which is 120 miles in length, and having our road already built and the equipment available for handling materials and poles, we have been able to build concrete poles for about the same cost as a wooden pole all fitted up and painted. We figure that a 32-ft. pole costs \$7.50 and a 45-ft. pole costs \$15, at pit. It is difficult to figure the cost of molds, as one mold should be good for a number of poles, depending on the care that is taken of it.

Pittsburg, Ft. Wayne & Chicago Ry.—In 1906 this company erected 53 poles for a mile of telegraph line near Maples, Ind. The general construction of these poles is shown by Fig. 9. They ranged in height from 25 to 34 ft. The 25-ft. pole shown by Fig. 9 was 8 ins. square at the butt and 6 ins. square at the top, the corners being chamfered to a face 2 ins. wide, so that above ground the pole was octagonal. The poles were set 4 ft. into the ground, and packed around with stone screenings. Some of the poles were erected within five days after molding.

Marshall Concrete Poles.—The following is a description of a test pole made by Mr. Wallace Marshall, Lafayette Engineering Co., Lafayette, Ind.

"In November, 1905, I made a box form of three sides, having the top open, for a test pole. It was 35 ft. long. The lower 5 ft. was 10 ins. square; commencing at that point it tapered on all sides to 6 ins. at the top. From the 5-ft. point I put a triangular piece in each corner of the form of about $1\frac{1}{2}$ ins. wide at the bottom and 1 in. at the top to chamfer the corners of the pole. At proper places of a standard line pole for line bracket, cross-arms and telephone box I bored holes through the forms, put machine bolts through it and let them extend about 2 ins. in the forms, screwing the nuts the full length of thread. In the top of the form, which was brought to a round point, I placed a $1\frac{1}{2}$ -in. pin in the center to leave a hole or an insulator pin. I then filled the form with concrete mixed by hand consisting of 1 part of cement to 6 parts ordinary gravel, except a facing of about $\frac{1}{2}$ in. of cement and sand 1 to 3. After covering the bottom of the form about $1\frac{1}{2}$ ins. I laid in the large end two $\frac{3}{8}$ -in. Thatcher bars 25 ft. long, and in the top part two $\frac{1}{2}$ -in. Thatcher bars, lapping them about 4 ft. I left them in the form six days. At the expiration of 30 days we tested it as follows: We planted it firmly in the ground 5 ft. deep. At 25 ft. distance we planted a large cedar telephone pole. At the level of 21 ft. from the ground we fastened a wire cable from one pole to the other, which is about the height of a trolley wire. In the center of this cable we suspended a barrel. Into this barrel we loaded steel rivets gradually and watched results. The two poles began to bend as the load was applied. When the two were deflected about 21 ins. each toward the other I observed a small check come in the concrete pole about 10 ft. from the ground, and simultaneously checks appeared from the cable to the ground. We immediately stopped loading, took off the ballast, weighted it and calculated the horizontal strain and found it to be 975 lbs. The maximum moment would be at the ground,

Eng. Contr.

Fig. 9.—Concrete Telegraph Pole.

but the guess at size we made was about right, since the concrete cracked from ground to cable at almost the same time. When the load was removed the pole resumed its plumb position and remains so to-day, although being used for heavy guy wires. The bolts were unscrewed before moving them, leaving the nuts imbedded in the pole. After concrete set we screwed the bolts into the nuts and could not loosen them with an ordinary wrench. It took several heavy blows with a sledge hammer to break out the top socket. My conclusions were, however, that a wire ring or two of reinforcement should be placed about the pin for safety. Careful estimates were made as to costs of such a pole 35 ft. long if made in quantities in proper forms with material at the then market price, and gravel in pit at \$7 actual cost. Comparing that cost with present price of pine poles and add to the latter the cost of trimming, chamfering, framing and painting, the concrete pole can be made for less money than the wood, provided no profit is paid a contractor. Figuring the moments on the pole tested I found the concrete failed at just about the time the limit of elasticity of the steel was reached, providing that it would be of no value without the steel. I believe that the concrete pole is practicable, and the only reason I have not put it to practical use has been the lack of time to do so."

Cost of Reinforced Concrete Piles for a Building Foundation.—In *Engineering-Contracting*, Mar. 24, 1909, a paper by Sanford E. Thompson and Benjamin Fox is published, of which the following is an abstract.

Arrange molding platform if possible so that butts of pile are placed to be drawn direct by pile driver.

Design butt so that pipe connection does not interfere with snatch ring. Place pipe connection so that hose can be connected before raising pile and supporting rope will not interfere with derrick hook.

If piles are made in cool weather and are to be driven in 30 days, strengthen concrete mix at butt by working some dry cement into it while ramming.

Use perfect rolls under driver to facilitate quick moving. The plan found best at Cambridge with the 4,700-lb. hammer was to begin driving by churning and water jet, using this method as long as possible. The chain connecting pile to hammer was then disconnected and driving began with hammer drop of about $2\frac{1}{2}$ ft., increasing drop as driving became harder; 4 ft. may sometimes be used at the start.

In ground not too hard it may be advisable after completing churning to give the chain a slack for a $\frac{1}{2}$ -ft. drop, and raise pile a little with a jerk after each blow. This appears to be effective only in ground soft enough so that the pile can be readily raised, and as it takes time to adjust chain, is hard on engine, and tends to start head crushing, it is of very doubtful value.

* a tip of pile should have good bearing on ground undisturbed

by water jet, the water should be shut off before the pile is down to grade.

The 8x8-in. tip was found to be slightly preferable to the 10x10-in. tip in time of driving. The 2-in. jetting pipe gave the best results, and it is suggested for future use that this be reduced to 1 in. or 1½ in. for the last 12 or 18 in. at the tip.

For piles of 30 ft. or less length the longitudinal reinforcement may be ¾-in. rods instead of ½-in., but for piles of over 30 ft. computations should be made so that the longitudinal reinforcement will be strong enough to stand the vibrating weight of the pile when it is being raised to the gins of the machine.

Design.—The piles as designed by Mr. Fox were made 30 ft. 8 in. long, 14 in. square at the butt end, and in general 9 in. square at the tip. A number of soundings were taken at the site of the power house which indicated a fill of from 6 to 8 ft.; below this to a depth of 29 ft. 7 in. to 31½ ft. from the surface, fine sand and mud (practically all may be considered sand); and below the sand a clay hard pan was reached which was tested to a depth of 13 ft. These tests, together with a consideration of the requirements, determined the length of the pile.

Of the 48 piles which were made, 6 were 8 in. square and 6 were 10 in. square instead of 9 in. at the tip. The object of this variation in size of the tip was to determine which size gave the best results. The irregularity of water pressure proved a very great handicap to making accurate comparisons and also affected very seriously the results obtained during the actual driving of each pile. Enough piles were observed, however, to give fairly good averages.

Averages of the time of actual driving the piles with different sized tips give the following results, which indicate that the 8-in. tip is slightly preferable in time of driving. The variation in the character of the ground as well as the water pressure may influence in a measure the relative times.

TIME DRIVING PILES WITH DIFFERENT SIZED TIPS.

Size of Tip. In.	Range in Time Driving. Mins.	Average Time Driving. Mins.
8	26 to 107	66
9	22 to 166	76
10	40 to 130	85

Piles were reinforced with four ¾-in. corrugated steel rods extending to within 2 in. of the ends of the pile, and imbedded 2 in. from the face near the butt and 1½ in. from the face at the tip. Loops of ¼-in. corrugated bars were placed around the principal steel, spaced about 12 in. apart except near the butt, where the spacing was decreased to 4 in., there being 34 loops in all. The butts of the piles were also extra reinforced, some with ¾-in. and some with ½-in. rods, varying in length from 2 to 3 ft. A ½-in. rod about 5 ft. long was imbedded in the concrete with a loop sticking out through the concrete near the top of the pile on one side for hooking with derrick.

A galvanized iron pipe was cast in the center of the pile for the water jet. For experimental purpose the sizes of pipes were varied, being 2 in., 1½ in., 1¼ in. and 1 in. To carry out the experiment still further some of the piles were made with one of the larger size pipes for about half the length of the pile and there connected with one of the smaller pipes which extended down to the tip.

The times of driving piles with different sizes of pipe in the interior of the pile were plotted, but the variation in each due to other causes was so great that no practical conclusion could be reached. The results simply indicate that the pile with 1-in. pipe took slightly longer to drive than the piles with larger sized pipe.

The friction of water running through pipe of small size is very great, so that it is known without experimenting that the largest size of pipe which it is practicable to insert in a pile will give the least loss of head and therefore be the best. To increase the velocity of the water, and thus increase its power to loosen earth (note that it is the velocity, not the pressure, which is increased), the size of the tube should be reduced near the tip. The reduction must be made far enough from the tip of the pile to prevent clogging under heavy blows. There is no danger of the nozzle filling while the water is flowing freely, and therefore no danger while the pile is being churned down in the first few blows. The danger is apt to occur when the driving becomes hard, and at this time the penetration per blow is so small that it would seem that a nozzle 12 in. long would be sufficient to prevent any material working up into the larger pipe. A 2-in. pipe is probably as large as is practicable, and it is therefore suggested that this size be used to within 12 in., or if preferred, 24 in. from the tip, and there reduced to 1 in.

Methods Employed in Making Piles.—The method of construction is as follows: A 3-in. platform of rough plank is built on ground of sufficient area to hold all of the piles. On this platform chalk lines are struck and V strips to form a 1-in. chamfer nailed so that the lines of the piles are about 6 in. apart, alternating points and butts. The casting of the piles with tips and butts alternating is economical of space, but where the piles are cast so as to be handled directly by the pile driver, without any intermediate handling, it is best to cast them all with the butts toward the machine on account of the saving of time in getting the pile in the gins. Two 8-in. unplanned (to assist in skin friction) spruce planks form the sides of each pile. The piles are made in lots of about five. The outside form is cleated with 2x4's, and the other sides have the plank simply set on edge with pairs of wedges between them. There are seven cleats or wedges in the length, and seven pieces 2x4 nailed across the top of each. After setting the plank sides, beveled pieces are nailed to locate the upper surface and form a chamfer.

Steel is wired together on a table consisting of plank on three horses. The reinforcement when made is suspended in form by two wires attached to each of the 2x4 cross pieces.

Two days were usually allowed before striking the forms.

GANG MAKING PILES.

One foreman	
2 laborers on miscellaneous work, at.....	\$0.25
4 laborers wheeling and mixing concrete, at.....	0.25
2 laborers ramming, at.....	0.25
4 carpenters, at.....	0.43 3/4
4 steel men (2 carpenters and 2 laborers), averaging	0.40

The concrete gank mixed and placed concrete in 10 piles in 10 hours. It took 4 carpenters 3 3/4 hours each, or a total time of 15 hours, to set up sides for 5 piles (10 sides), and 4 carpenters 1/2 hour each, or a total of 2 hours, to take down the sides for 5 piles. It took one carpenter and one laborer 10 hours each to wire up 5 reinforcing frames and place them in form ready for concreting.

Each frame was composed of four 1/2-in. rods in corners running full length of pile, 1/4-in. hoops 12 ins. on centers except for 2 ft. at the top, where hoops were spaced 4 ins. on centers. Four additional 1/2-in. rods 2 ft. long and a 1/2-in. bent rod for hooking the pile were placed at this same end. A 1 1/2-in. pipe was also placed in the center of the pile.

The concrete was mixed by hand in the proportion of 1-2-4, using 3/4-in. trap rock, the sand and cement being first made into a mortar and the stone added. A thorough mix is of course essential. Mixing was started in March, precautions being taken at night against possible frost and the piles wet down every day for two weeks.

The age of the piles when driven ranged from 30 to 41 days, the larger part of them being nearer the shorter age, the average being 33 1/2 days. The first pile was molded on March 24 and driven on April 24, and during this period the temperature was low, averaging between 40° and 50° F., so that the piles had not attained nearly their full strength. After the driving was commenced the weather became much warmer, and the piles after the first few were noticeably harder and entirely satisfactory, even although the age was practically the same, that is, about one month. The first pile driven lost its water pressure when about 6 ft. below the surface, and during the process of driving, which reached 700 blows, it is probable that it broke when about half-way down. The head of this pile was badly crushed, whereas subsequent piles which had hardened more thoroughly because of the higher temperature were uninjured, even with a similar number of blows and higher drops of the hammer.

It may be said, therefore, that a period of one month for seasoning piles is sufficient during, say, the months between May 1 and October 1, but during the colder months a longer period should be allowed unless artificial heat can be used to hasten hardening.

Pile Driver and Hammer.—It was decided, after a careful investigation of records of concrete pile driving both in this country and Europe, to use a 4,700-lb. hammer. With a view to the use of the heavy hammer and the side strains brought to bear on the

machine by the dragging of the piles from the casting platform, a special driver was built. The driver was made as follows:

Long leaf hard pine was used throughout. The bed timbers were 8x10 in., 18 ft. in length, the gins 8x8 in., 42 ft. long. The braces of 8x8 in. timber were run from the bed timbers to the head of the machine with intermediate braces and ties to give the necessary rigidity. The sheave was of extra heavy pattern and the whole framework was bolted up and tied together with rods. The cushion head, which was perhaps the most essential item, as it was desired to avoid fracture of the pile from the blows of the 4,700-lb. hammer, consisted of a plate iron collar 16 in. square on the inside and 3 ft. in height, which incased an oak block 16x16x18 in. on to the bottom of which six thicknesses of rope and four layers of rubber belting were nailed. The cushion head was held in place in the gins of the machine by four perpendicular pieces of oak on the outside of the collar and bolted through the incased oak block. A 26-hp. Lambert engine was used and a single block for hoisting and churning the piles.

The water for jetting was furnished through a 2½-in. Bay State hose, using a compound piston pump having 7x12-in. high pressure, and 12x12-in. low pressure cylinders, and a capacity of 100 gallons per minute. This was the most unsatisfactory part of the entire work, the water pressure being invariable and uncertain and 125 lbs. the limit of pressure obtainable at the pump.

Driving Piles.—The usual process of driving consisted, after moving the pile driver, in hooking and dragging the pile and lifting it to place and attaching the hose, or attaching the hose first and then hoisting.

As already shown the casting of the piles with tips and butts alternating is economical of space, but where the piles are cast so as to be handled directly by the pile driver, without any intermediate handling, it is best to cast them all with the butts toward the machine on account of the saving of time in getting the pile into the gins of the machine. When the pile is cast with the butt end toward the machine the pile can be lifted directly into the gins, while, when the pile is cast with the tip end towards the machine, it must be chained and dragged in front of the machine before it can be hooked in the usual manner and lifted to place.

Care must be taken when making the pile to place the hook for hoisting in relation to the projecting nozzle for jetting so that the hoisting rope will not foul the hose when the pile is being raised into position. To facilitate setting the pile into the gins, a crutch of 1-in. iron was made with a 12x12-in. square key at one end with a long handle to replace the peavy or cant dog ordinarily used for wood piles. As soon as the hose was attached and the pipe in place, the water was turned on and the pile usually penetrated for a short distance without the hammer. The hammer was then placed on the cushion and the pile sank further to a depth depending upon the nature of the fill. Next the hammer was attached to the pile with a chain and the churning commenced. There was enough play

In the chain connection between the hammer and the pile to give about a 10-in. blow of the hammer each time the pile was lifted. When this churning became ineffective, the chain was disengaged and the pile was driven with blows in the usual manner.

GANG ON PILE DRIVING.

1 foreman, at \$0.50 per hr.....	\$ 4.00
1 engineman, at \$0.50 per hr.....	4.00
1 pump man, at \$0.25.....	2.00
7 men, at \$2.50 per 8 hrs.....	17.50

Total gang per 8 hrs.....\$27.50

In addition to this gang 2 carpenters were called in occasionally for repairs, and 2 other laborers were busy most of the time in connection with cutting off piles, digging holes and odd work.

Gross Times Driving.—For convenient reference gross times driving piles are tabulated in Table I (not reproduced here) together with some of the more important details. The times, for example, are separated into "Moving Driver," "Placing Pile," "Driving" and "Delays;" and the "Number of Blows," the "Range in Drop" of hammer, and the drop and penetration under "Last Blow" are also given.

The total average time per pile is 2 hrs. and 15 mins., of which 29 mins. is moving driver, 23 mins. placing pile and 83 mins. driving (not including 27 mins. delays from various causes). This corresponds to an average of $3\frac{1}{2}$ piles per 8 hrs., which agrees with the time that can be figured directly from the beginning to end of the job. As the men became more expert in moving the driver and placing the piles, it was possible to reduce the time to $1\frac{1}{2}$ hrs., as shown by the average during the last four days. Even this includes about one-half hour moving pile driver, which was unnecessarily long because of imperfect rolls.

The time driving was greatly increased by the poor water pressure. Taking an average of 16 piles whose time was less than 60 mins. and which, therefore, might be assumed to have gone down fairly well, the time during the driving was 44 mins., thus giving a total of 1 hr. and 24 mins. per pile, or 5.75 piles per day instead of 2.5 piles per day.

It therefore may be assumed on another job of similar character that an average of at least $5\frac{3}{4}$ piles may be driven per day. By using perfect rolls, molding piles with butts toward pile driver, and using good water pressure, this number may be still further increased. From a study of the individual items, times may be selected and estimates made which will apply to other locations and other conditions.

Each pile received an average of 589 blows.

Instances of Hard Driving.—One of the first piles that was driven probably struck a large bowlder at 18 ft. below the surface. The pile was given 735 blows, using drops of the hammer of from 18 to 30 in. At this stage the head was so badly crushed that the driving was stopped and the projecting portion of the pile cut off. To see what effect this tremendous pounding with a 4,700-lb. hammer

had on the pile, after squaring off the crushed head it was sent to the Watertown Arsenal to be tested. The Arsenal report was as follows:

TESTS BY COMPRESSION, CONCRETE PILE No. 12,221.

Length, 9 ft. 3 in.

Size of butt, 12.9 in. by 12.75 in.

Size of tip, 11.15 in. by 11.75 in.

Weight, 1,453 lbs.

Cross-sectional area (smaller end), 128.59 sq. in.

Ultimate strength, 497,000 lbs. = 3,865 lbs. per sq. in.

Remarks.—Pile failed at smaller end, opening oblique and longitudinal cracks.

Attention should be called to the fact that the pile failed at the smaller end and not at the end receiving the hammer blows. This indicates that the pile was not materially damaged by the severe hammering it received, except at the immediate point of contact. An examination of tests of reinforced columns at the Watertown Arsenal shows, for columns of the same proportions of concrete and same age, and reinforced with four longitudinal rods varying from $\frac{3}{4}$ in. to $1\frac{1}{4}$ in. a range of 2,000 to 3,000 lbs. per sq. in. based on the total cross section of the concrete and steel. It will, therefore, be seen that notwithstanding the severe treatment of the pile in driving, the ultimate strength was considerably higher than the average strength of similar columns. Evidently the strength of the pile was not appreciably affected by the driving or by the crushing of the head.

Cost.—The cost of the materials and the labor are tabulated in detail in Table XI. The labor costs are taken from the timekeeper's record, but are sufficiently subdivided to be useful for other jobs of a different character. The items which vary directly with the number of piles are separated from the costs which are independent of the number of piles, but must be applied to any job as a constant expense. Only a few items depend upon the character of the ground.

The lumber for the forms (except the platform) is assumed to be a constant for any job, because it can be used over and over. The size of the platform must vary with the number of piles.

The pile driver for any one job is figured at 25 per cent of the initial cost for depreciation and interest, but the cost of repairs is included in the items which vary with the number of piles.

The costs which are variable are given per linear foot of pile for subsequent use. It will be seen that the total cost per linear foot of pile on this particular job was about \$1.63. If the length of piles differed greatly from those given, it might be necessary still further to separate the cost to provide for this.

A study of the various items taken in connection with a study of the detail times suggests various places where the cost may be altered for other jobs.

For example, an inspection of the costs shows that the cost of the reinforcing steel is over one-third the cost of the piles. From the fact that piles withstood the severe usage given by the pile driving, it is probable, if the piles are not over 30 ft. long, that $\frac{3}{4}$ -in. steel instead of $\frac{1}{2}$ -in. could be used for the corner rods,

TABLE XI.—COST OF DRIVING PILES ON B. W. H. & R. COMPANY JOB.

	Total.	Per lin. ft. of pile.
(1) 6,000 ft. B. M. plank for platform @ \$0.25.4...\$	27.50	\$0.0256
(Lumber cost \$25 per thousand and assumed to be used for four times.)

		\$1.63

*After deducting \$60 assumed as constant "getting ready."

†Only items affected by character of ground.

with extra reinforcement near the butt, as in the present case. The size of these rods can be determined by figuring the stress in them during the process of raising the pile to place. The pile is then a beam supported at the ends and carrying its own weight, which must at least be doubled to provide for swaying incident to the

raising. The cost of the item of steel and labor would in such cases be varied accordingly.

The labor on concrete appears large, and might probably be reduced on another similar job from \$111 to about \$74. This is based on the fact that, while on the average only 6 piles were made, toward the latter part of the making 9 piles were made on one day and 10 piles on another, so that an average of 8 piles should be possible with the given gang. This is especially probable because the cost of making and placing the concrete was \$2.32 per pile, or \$2.25 per cu. yd., whereas the writer's data on hand mixing indicate that the cost should not have exceeded \$1.50 per yd.

With reference to the time and cost of the driving, it must be taken into consideration that the job was a small one, only 48 piles being needed; that the work was of an untried character; and also that the conditions were unfavorable, especially as regards the water pressure. On a large job, in ordinary ground, where large stones or obstructions are not likely to be encountered, the number of piles driven per day should be greatly increased. A study of the detail log of the driving tests and a comparison of these times with detail records taken on other jobs, indicate that the average time per pile driven with the aid of a water jet may be easily reduced to one hour, while if the ground is very soft, the average time per pile, including the moving of the driver, need not be over 40 mins. One hour per pile corresponds to 8 piles per eight-hour day, instead of $3\frac{1}{2}$ piles per day. The estimated time on the items near the foot of the cost table, which is inversely proportional to the total number of piles given, would be decreased on a job having 200 piles from \$0.139 to \$0.035 per foot of pile. This, together with the reductions noted above, and the assumption of 8 piles driven per eight hours, would bring the estimated cost per linear foot down to \$1 net, or, with 25 per cent allowance for pump hose connections, incidentals and profits, to \$1.25 per linear foot. In soft ground, and where conditions are specially favorable, a still lower estimate is possible.

A few of the items, such as the nipples and short bars, are constant per pile, that is, are independent of the lengths of the pile, so that in a close estimate for longer or shorter piles they should be separated out or allowed for by inspection.

As it assumed in the estimate in the last column that 8% piles are driven in 8 hrs., the total cost for harder or softer ground can be estimated by assuming the number of piles to be driven per day and varying the items marked with a † accordingly.

Records of six of the typical piles are plotted and the curves are shown on the diagram (Fig. 10).

The full curves in Fig. 10 show the portion of the driving where the water pressure was on and the dotted lines the driving after it had been cut off by the filling of the pipe at the tip of the pile. This stoppage was not necessarily due to the design of the pile or to the method of driving, but chiefly to the insufficient capacity of the pump.

The flattening out of the curves indicates difficulties in driving.

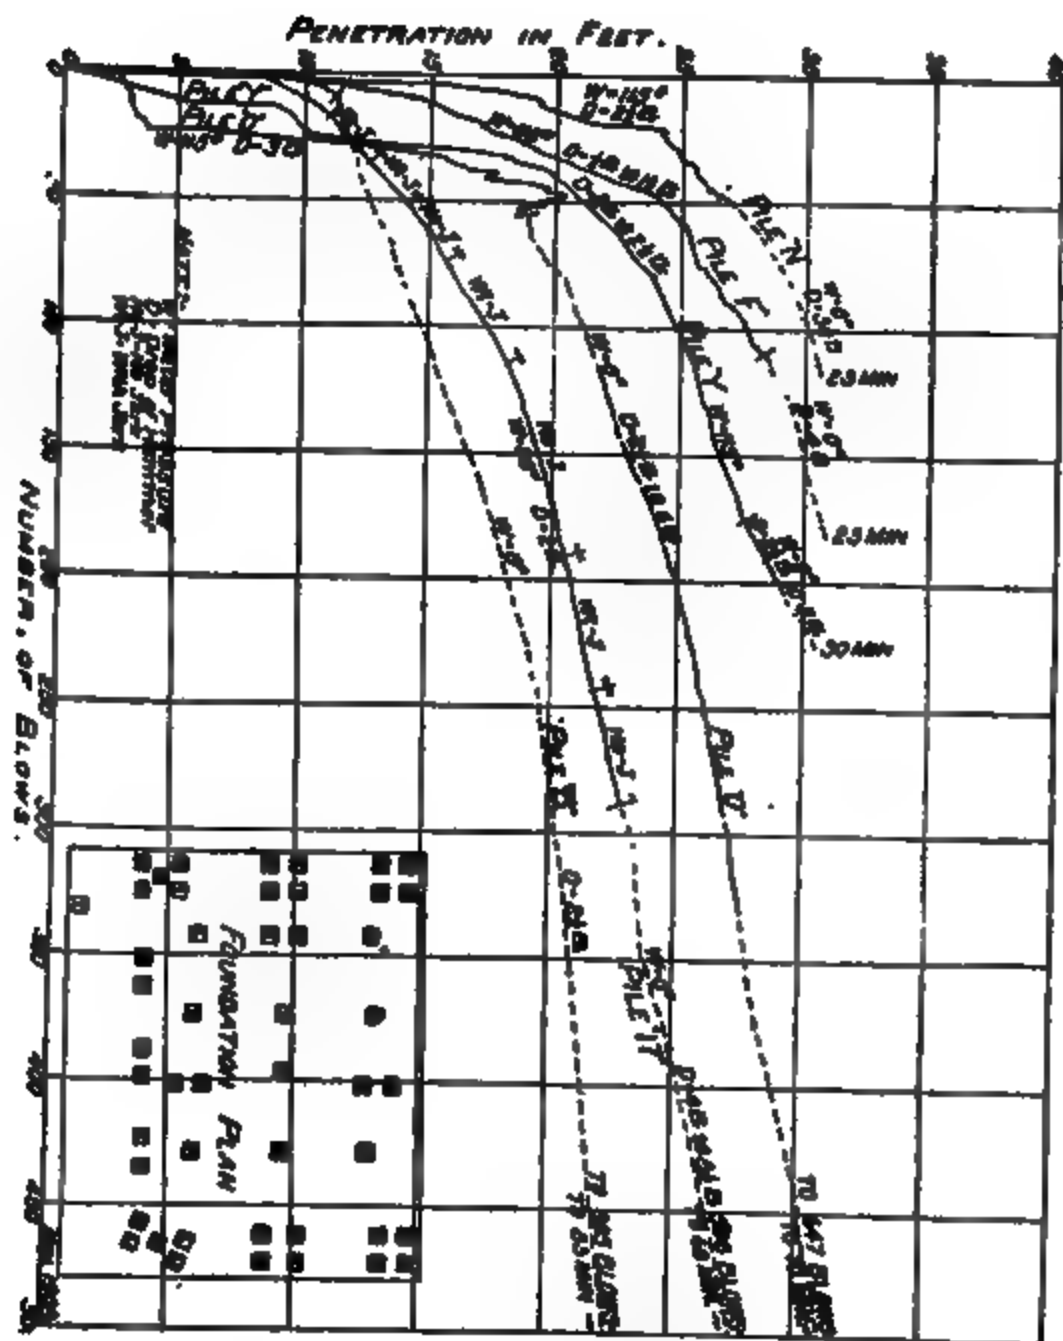

Fig. 10.—Records of Pile Driving.

usually because of the poor water pressure. In certain cases irregularities indicate the striking of obstructions, and when the pile is slightly jerked ground is lost instead of gained.

Curves of piles *N*, *F* and *Y* are given to show good driving, the pressure remaining on most of the time, and the total net time, omitting all unnecessary delays, being from 23 to 30 mins.

Piles *F* and *Y* show also that if a greater drop of hammer had been used at the start they would probably have approached nearer the *N*.

In driving pile *N* at 24-ft. depth, the hammer was allowed just to tap the top of the pile with no impact, and the pile being slightly churned, the loss of progress is shown by slight drop in curve. Then by increasing the height of the blow it started down again. Time, 23 mins. with 118 blows.

On pile *F* they first began jerking the pile after each blow, and this method appears to be effective provided ground is soft enough actually to lift pile readily. In hard ground it is ineffective. Drop of hammer was increased from 0.5 to finally 4 ft. Time driving 24 minutes with 135 blows.

Pile *Y* was not churned or lifted after first blow or two, but went down with light blows. Time, 30 mins., 225 blows. Pressure good.

The curve of pile *B* is given to illustrate hard driving, due to lack of water pressure. The water pressure stopped at 11½-ft., as shown by the sudden break in curve at this point. Total time driving pile was 83 mins. with 895 blows.

In the curve of pile *O* there is an interesting break at the depth of about 20 ft., where an effort was made to assist the pile by churning or jerking, and ground was lost by doing so, and the pipe was also allowed to plug. As soon as the hammer was allowed to drop in the usual way the penetration began again, but 647 blows and 70 mins. by net time were required to carry it to its full depth. At a depth of 2¼ ft. an obstruction was met, as indicated by the curve, and a small broken piece of timber came up beside the pile. Another reason for the flat curve of pile *O* is that the ground was unusually hard.

Pile 17 was driven in an experimental fashion to determine the effect of the jerk at the end of each blow. The curve is uniform throughout, showing that this jerk is absolutely ineffective in hard ground. In this pile, as noticed, the height of drop was increased to 8½ ft.

Cost of Reinforced Concrete Piles for an Ocean Pier.*—In reconstructing in reinforced concrete the old steel pier at Atlantic City, N. J., some 116 reinforced concrete piles 12 ins. in diameter were molded in air and sunk by jetting. The piles varied in length with the depth of the water, the longest being 34½ ft. Their construction is shown by the accompanying drawing (for these drawings see Gillette and Hill's "Concrete Construction"), which also

**Engineering Contracting*, Nov. 28, 1906.

show the floor girders carried by each pair of piles and forming with them a bent, and the struts bracing the bents together. In molding and driving the piles the old steel pier was used as a working platform.

The forms for the piles were set on end on small pile platforms located close to the positions to be occupied by the piles and were braced to the old pier. The forms were of wood and the bulb point, the shaft and the knee braces were molded in one piece. Round iron rods were used for reinforcement. The concrete was composed of 1 part Vulcanite Portland cement, 2 parts of fine and coarse sand mixed and 4 parts of gravel 1 in. and under in size. The mixture was made wet and was puddled into the forms with bamboo fishing rods, which proved very efficient in working the mixture around the reinforcing rods and in getting a good mortar surface. The concrete was placed in small quantities; it was mostly all hand mixed. The forms were removed in from 5 to 7 days, depending on the weather.

The piles were planned to be sunk by water jet and to this end had molded in them a 2-in. jet pipe as shown. They were sunk to depths of from 8 ft. to 14 ft. into the beach sand. Water from the city water mains at a pressure of 65 lbs. per sq. in. was used for jetting; this water was furnished under special ordinance at a price of \$1 per pile, and a record of the amount used per pile was not kept. The piles were swung from the molding platforms and set by derricks and block and fall. The progress of jetting varied greatly owing to obstructions in places in the shape of logs, old iron pipes, etc. In some cases several days were required to get rid of a single pipe. In clear sand, with no obstructions, a 12-in. pile could be jetted down at the rate of about 8 ft. per hour, working 1 foreman and 6 men. The following is the itemized actual cost of molding and sinking a 26-ft. pile with bulb point and knee braces complete:

Forms.	Total.	Cost per pile.
Lumber, 340 ft. B. M. @ \$30.....	\$10.20
Labor (carpenters @ \$2.50 per day).....	12.00
Oil, nails, oakum, bolts, clamps, etc.....	1.20
	<u>\$23.40</u>	\$ 3.90
Times used.....	6
<i>Reinforcement.</i>		
275 lbs. of plain $\frac{1}{4}$ -in. steel rods @ 2 cts. per lb.....	\$ 5.50
Preparing and setting, $\frac{1}{10}$ ct. per lb.....	1.10	6.60
<i>Jet Pipe.</i>		
26 $\frac{1}{2}$ ft. of 2-in. pipe @ 10 cts. per ft. in place	2.65
<i>Setting Forms.</i>		
6 men @ \$2.50 per day = \$15, set 4 piles	2.75
<i>Material.</i>		
90/100 cu. yds. gravel @ \$1.50 per yd.....	1.35
45/100 cu. yds. sand @ \$1.50 per yd.....	.67
1.50 bbls. cement @ \$1.60.....	2.40	4.42

Labor.			
Concrete and labor foreman.....	2.00	
6 laborers, mixing and placing by hand, \$1.75 each.....	10.50	
	<u>\$12.50</u>		\$ 2.28
Average number of piles concreted per day	4	
Removing Forms.			
4 men @ \$2.50 remove and clean in half day 4 columns.....		1.25	
1 man @ \$2.25 plastering column with cement grout (4 per day).....		.56	
Jetting 10 ft. into Sand.			
Foreman	\$ 2.00	
4 men, \$2.25 each, handling hose and traveler	9.00	
	<u>\$12.00</u>		\$ 2.00
Average number of piles jetted per day...	4	
City water pressure used for jetting @ \$1.00 per pile.....		1.00	
Superintendence @ \$5.00 per day.....		1.25	
Caring for trestle, traveler, material, etc.		4.84	
		<u></u>	
Total cost per pile.....			\$36.60

The pile being 26 ft. long, the cost in place was \$1.41 per foot. Subtracting the cost of sinking, amounting to \$7.09 per pile, we have the cost of a 26-ft. pile molded and ready to sink coming to about \$1.10 per foot. It should be noted that this is the cost for a pile of rather complicated construction; a plain cylindrical pile should be less expensive.

During a visit to Atlantic City one of the editors of this journal took occasion to examine closely these 12-in. piles. They were then about four or five months old, and were in all respects as sound and smooth examples of concrete work as could be wished. The surface texture of the piles was notably good; the piles appeared to have a surface film or skin which he then took to be some saline incrustation coming from the sea water. A statement since received from Mr. D. A. Keefe Consulting Engineer, Athens, Pa., who was resident engineer of the pier work, and to whom we are indebted for the figures of cost given above, mentions that the piles are covered with a coating of organic and inorganic nature which fills the pores of the concrete and will in time form a coating of considerable thickness which should have the effect of shutting out the sea water and preventing any disintegration. In conclusion, it should be noted that the design of the concrete steel work employed in reconstructing this pier was worked out by the Concrete Steel Engineering Co., of New York City, and that the contractors for the work were C. W. Snyder & Co., of Atlantic City, N. J.

Cost of a Reinforced Concrete Pile Dike.*—The work described is a reinforced concrete pile dike built opposite St. Joseph, Mo., on the Missouri River improvement work. This is the first dike of reinforced concrete to be constructed on the Missouri River and

**Engineering-Contracting*, Oct. 20, 1909.

is an experiment to secure a better and more durable structure than is provided by the usual timber pile dike having a life of from 7 to 10 years. Several plans were considered and are described by Maj. Edward H. Schulz.

The plans considered besides the one adopted were: (1) Sinking a core with shell, withdrawing core, and filling the shell with concrete; (2) casting the pile in place, the form being gradually removed as the filling proceeds; (3) rolling and making the pile on the ground by special machine. The adopted plan was to use cast piles of rectangular or octagonal section and to drive them by hammer and water jet combined. Bids were asked for supervising the work and furnishing forms and reinforcement, the Government to furnish all other materials, to make the piles and to drive them. The lowest bid was 80 cts. per lin. ft. of pile.

The dike structure consists of 3-pile bents connected at tops of piles, and at about water level with horizontal transverse and longitudinal braces. The length of the dike is 150 ft., of which 40 ft. at the shore end consists of timber piles. A length of 110 ft. was constructed of concrete piles. The bracing was all wood except in two panels, where as an experiment concrete braces were used. The total number of concrete piles was 26, varying in length from 32 to 50 ft., and having a total length of 1,457 lin. ft. The piles were 14 in. square at top and 8 in. square at the point. Each was reinforced with 4 1-in. bars tied every 18 in., with 1½-in. bars. The concrete was a 1:2:4 mixture, using Ash Grove Portland cement and 1-in. stone. The piles were driven at the age of 10 days; the average penetration was 21 ft.

The piles were cast on a foreshore at an elevation of about 6 ft. above the deck of a barge in the river. Skids were placed from the foreshore to the barge, and as the forms were removed the piles were slid on-board, somewhat similar to the handling of wooden timbers of like size. The approximate weight of a 50-ft. pile is 8,700 lbs.

On account of the excessive weight of these piles over wooden piles of the same length, wire cable was used, using a single and double block for increasing the purchase. The hitch for raising the head of the pile was placed about 8 ft. from head. The ordinary pile line was used to raise the point of pile, the sling being placed about 15 ft. from the small end of pile. This arrangement takes the spring out of the pile. The catenary of a 50-ft. pile is about 5 in. without injury to pile.

A device, known as a guide, was placed around the pile near the head in such manner as to hold the pile squarely in the leads. The pump used was a single cylinder, double action, 6-in. suction, 8-in. discharge, 1½-in. nozzle, 80 strokes per min., and 80 lbs. steam pressure. A piece of 1½-in. pipe was placed in the end of the pile, to which the jet was attached. Other than this the method of sinking was the same as for wooden piles of like size.

The piles were driven near shore, where unusual difficulties existed, due to parts of old dike and rock buried in river bed. Under

normal conditions, where only sand is encountered, the pile was jettied in 3 to 5 mins.; no hammer was used, but occasionally the pile itself was lifted and dropped to hasten the work. It is believed a judicious use of jet and hammer will be found advisable for future work.

This dike was examined after going through an ice and flood season and was found to have stood very satisfactorily. Not a pile or concrete brace was injured, though several wooden braces were broken. Should results continue with similar success, it is probable that concrete dikes will receive serious consideration as a permanent substitute for timber piles on river regulation.

The cost of the dike was as follows:

Item.	Total.	Per lin. ft.
Supervising, forms and steel rods....	\$1,200.00	\$0.3238
86½ bbls. cement at \$1.25.....	108.44	0.0743
65.9 tons crushed stone at \$1.30.....	72.67	0.0495
22 cu. yds. sand at 20 cts.....	6.40	0.0043
Labor on forms.....	117.00	0.0303
Labor making piles.....	257.70	0.1763
Labor driving piles.....	215.00	0.1475
Total	\$1,977.21	\$1.2566

In regard to these figures Mr. Schulz says: "The actual cost, deducting profit of contractor and cost of special supervision, would be \$1 per ft. On extensive work this could probably be reduced to 40 cts. per lin. ft. of pile, as compared to 20 cts. for long-leaf yellow pine."

Cost of Raymond Concrete Piles.*—The following figures of the cost of constructing concrete piles by the Raymond process have been computed from records obtained in constructing the pile foundations for the concrete laundry building of G. L. Hooper & Sons, of Salem, Mass. The building is of concrete throughout, the walls being of concrete block and the columns, floors and roofs of reinforced concrete. There are four stories and the general dimensions are 60 x 100 ft. The floor and wall loads are transferred to wall columns and to two rows of interior columns. The columns are spaced 14 ft. apart on centers in one direction and 19 ft. in the other direction. Each column and its footing rests upon four concrete piles spaced 3 ft. apart on centers in the form of a square. The spandrels between wall columns are reinforced concrete. The groups of four piles are each capped with a concrete slab 5 ft. 6 ins. square and 24 ins. thick, making the projection of the capping beyond the center of the piles 15 ins. Each pile was finished so as to allow a projection into the capping of 6 ins. A concrete chimney, 48 ins. in diameter and 100 ft. high, located at one corner of the building, is supported upon a group of nine piles. Each of these piles has embedded in it a steel rod which projects into the walls of the chimney, forming an anchorage.

As firm bearing soil was some distance below the ground, piling of some sort was necessary, and wood piles were originally consid-

**Engineering-Contracting*, Feb. 12, 1907.

ered. This would have made it necessary to cut off the wood piles below low tide, a distance of 12 ft. below the level of the ground floor, and using a large amount of concrete in the stepped footings above. Instead, concrete piles were used which were cut off 5 ft. below the ground floor, effecting considerable saving of concrete foundations. Another feature which made the use of concrete piles desirable in this instance was the fact that the site of the building was formerly occupied by an old wharf, the timbers of which were many of them yet in the ground. Had wood piles been used, difficulties would probably have been experienced due to the "brooming" of the piles when striking such obstructions. With the steel driving form used for the concrete piles, delays from this source were avoided. The piles are designed for a load of 30 tons each, and each takes the place of two wooden piles in the original design. They are 6 ins. in diameter at the small end and have a uniform taper each side of the center of $\frac{1}{8}$ in. to a foot, making a 21-ft. pile 20 ins. in diameter at the top.

In constructing concrete piles by the Raymond process, as many of our readers will remember, a thin steel shell enveloping a metal core is driven and then the core is collapsed and withdrawn, leaving the shell, which is afterwards filled with concrete in which metal is embedded if a reinforced pile is desired. In this particular work no reinforcement was used in the piles.

The piles were driven by means of a No. 3 Vulcan steam hammer, with a plunger having a weight of 3,000 lbs. and a fall of about 3 ft., delivering 60 blows per min. A steel driving form encased in a shell of about No. 20 gage iron was first driven to the required depth; the steel driving form was then withdrawn, leaving the shell in place, and the concrete afterwards deposited in this shell. A total of 172 piles were driven, the minimum length being 14 ft. and the maximum 37 ft., the average being about 20 ft. Sixteen working days were occupied in driving the piles after the driver was in position, driving being commenced Aug. 17 and completed Sept. 6, 1906. The greatest number driven in one day was 20, and the average was 11 piles per day. When in position for driving the average time required to complete driving was 12 mins. The total number of blows varied from about 210 to 360, the average being about 250. The piles were driven until the penetration produced by 8 to 10 blows equalled 1 in. When in full operation, a crew of 6 men operated the pile driver. Seven men were engaged in making the concrete and 5 men working upon the metal shells.

Assuming the ordinary organization and the wages given below, we have the following labor cost per day:

1 foreman at \$5.....	\$ 5.00
1 engineman at \$3.....	3.00
4 laborers on driver at \$1.75.....	7.00
6 laborers making concrete at \$1.75.....	10.50
5 laborers handling shells at \$1.75.....	8.75
Total	\$34.25

As 172 piles averaging 20 ft. in length were driven in 16 days,

the total labor cost of driving, given by the figures above, is $16 \times \$34.25 = \548 , or practically 16 cts. per lin. ft. of pile driven.

The concrete used in the piles was a 1:3:5 Portland cement, sand and $1\frac{1}{2}$ -in. broken stone mixture. A 20-ft. pile of the section described above contains about 20 cu. ft. of concrete, or say 0.75 cu. yd. We can then figure the cost of concrete materials per pile as follows:

0.85 bbl. cement at \$1.60.....	\$1.36
0.36 cu. yd. sand at \$1.....	0.36
0.60 cu. yd. stone at \$1.25.....	0.75
Total per pile.....	\$2.47

The steel shell has an area of about 72 sq. ft., and as No. 20 gage steel weighs 1.3 lbs. per sq. ft., its weight for each pile was about 94 lbs. Assuming the cost of coal, oil, etc., at \$2.50 per day, we have the following summary of costs:

	Per lin. ft. of pile.
Labor driving and concreting.....	\$0.16
Concrete materials.....	0.123
94 lbs. steel shell at 3 cts.....	0.145
Coal, oil, etc.....	0.011
Total	\$0.439

This cost does not include interest on plant, cost of moving plant to and from work and general expenses, nor royalty on the Raymond patent.

The contract was awarded for a fixed number of lineal feet of pile at the rate of \$1.50 per lin. ft., with a provision for additional length of piling to be furnished at \$1.40 per lin. ft., the contractors providing all tools, machinery, material and labor required for the work. The owners, through the contractor for the building proper, made the necessary excavations and provided clear and level space for the pile driver, braced all trenches.

For the cost of Raymond piles at another place, see "Concrete Construction" by Gillette and Hill.

Cost of Rolled Concrete Piles.*—The abutments of the Chicago & Northwestern Ry. bridge over the Root River at Racine, Wis., are founded on reinforced concrete piles manufactured by the Chenoweth rolling process. The cost of these piles is given by Mr. L. C. Winkelhaus as follows: "The contract price for these piles was 60 cts. per lin. ft., or \$9.60 per pile 16 ft. long. The railway company furnished all the materials, costing \$6.48 per pile, or 40 cts. per ft. The general contractor received 50 cts. per ft. for driving, or \$8. Hence, the cost to the railway company was \$24.08 per pile in place, or \$1.50 per ft. The cost to the American Concrete Co. for rolling was 25 cts. per ft., or \$4 per pile, approximately. The machine and plant cost the concrete company about \$3,000. However, this machine can be moved from place to place and used a great many times, as it is all bolted together."

**Engineering-Contracting*, Aug. 18, 1909.

The method of making concrete piles by rolling, and detailed cost, will be found in "Concrete Construction" by Gillette and Hill.

Cost of Simplex Piles.—Mr. Constantine Shuman gives the following relative to work done in Pittsburg in 1904:

One gang working on Simplex piles 30 ft. long averaged 450 lin. ft. per day, or 15 piles, but the best day's work was 31 piles, or 930 lin. ft. The crew was as follows, and I have assumed rate of wages, etc.:

	Per day.
1 foreman	\$ 4.00
1 engineman	2.00
2 winch head men, at \$1.75.....	3.50
3 riggers, at \$2.00.....	6.00
Total pile driver gang.....	\$16.50
6 concrete mixers, at \$1.75.....	10.50
Total gang	\$27.00
Rent of driver and apparatus, and fuel.....	18.00
Total, exclusive of materials.....	\$45.00

This is equivalent to 10 cts. per lin. ft.

The piles are 17 ins. diameter, composed of 1:2½:6 mixture. There are 1.58 cu. ft., or 0.069 cu. yd. per lin. ft. of pile.

For description of methods of making Simplex piles and the special pile points, see Reid's "Concrete and Reinforced Concrete Construction."

Cost of Concrete Oil Tank.*—Mr. C. F. Leonard gives the following data:

The wall forms a building housing a circular steel oil tank; it is 42 ft. inside diameter, 25 ft. high and 12 ins. thick. The reinforcement consists of ½-in. twisted steel rods located 2 ins. inside the exterior face and spaced apart from 3½ ins. at the bottom to 30 ins. at the top. Vertical rods 9 ft. apart around the wall held the horizontal rods in place. To tie the wall to the bottom L-shaped ½-in. rods 7 ft. long were used. Lap splices 33 ins. long were employed.

The forms were made in panels 6 x 8 ft., of ½-in. spruce boards 6 ins. wide dressed on one side and both edges and nailed to three segments of 2 x 12-in. plank cut to curve. For the first three shifts the forms were braced on both sides. A ½-in. rope with turnbuckles was passed around the steel tank, and the forms were drawn against spacing blocks, set between the steel tank and the inside form and also between forms, by wire ties fastened to the wire rope. The outside panels were also braced from the ground. Above this level the panels were held in position by bolts through the concrete wall.

The concrete for the bottom 15 ft. of the wall was a 1:2:3½ 1-in. stone mixture; above this level the cement content was reduced. It was mixed wet by hand and wheeled up inclines to the tops of the forms. The first ring 5½ ft. high, was concreted in one day; afterwards the forms were shifted for about one-third the circumference at a time and the concreting was done in a spiral course.

* *Engineering-Contracting*, Oct. 21, 1908.

Grooved joints were made whenever work was stopped. Frames for windows and doors were cast separately and set in place as the concreting progressed. The wall was painted with two coats of neat cement both inside and outside.

The cost of the wall was as follows:

Item.	Per cu. yd.
Cement at \$1.70 per bbl.....	\$ 2.81
Sand at \$1.35 per cu. yd.....	0.66
Stone at \$1.20 per ton.....	1.42
Labor at \$1.75 per 8 hra.....	4.25
Reinforcement	1.65
Lumber, nails and supplies.....	1.46
Carpenters' labor.....	5.25
Total	\$17.50

The cost of carpenter work was over twice what it should have been, owing to local conditions.

Cost of Concrete Tanks, References.—See section on Waterworks for data on this subject. Also see Chapter XXI, Methods and Cost of Construction Reservoirs and Tanks, in Gillette and Hill's "Concrete Construction."

Cost of Small Cement Pipes.*—Mr. Albert E. Wright is author of the following: The pipe discussed here was 6 to 12 in. inside, made of Portland cement and clean, sharp sand of all sizes up to very coarse. The mortar was mixed rather dry, but very thoroughly, using 14.1 cu. ft. of sand to 1 bbl. of cement, or very closely a 1 to 4 mixture. From six to seven buckets of water were used to each barrel of cement, except for the 6-in. pipe, for which the mortar had to be made somewhat stiffer in order to remove the inner form, which is not made collapsible as in the larger sizes.

The forms were sheet iron cylinders with a longitudinal lap joint that could be expanded after molding the pipe, and removed without injuring the soft mortar. The inner form was self-centering, so that there was little variation in the thickness of the pipe.

Four men are required in making cement pipe by hand; one mixes the mortar, and wheels it to the place of work; another throws it into the form a little at a time with a hand scoop; a third rams it with a tamping iron, and a fourth keeps the new pipe sprinkled, and applies a coat of neat cement slurry to the inside when it is sufficiently hard. In molding, the form of the bell at the bottom is secured by an iron ring that is first dropped into the form, and the reverse or convex form at the top is made with a second ring. While still in its form the pipe is rolled or lifted into its place in the drying yard, and the form is then carefully removed. A very slight blow in removing the form will destroy the pipe, and a considerable number, especially of the larger sizes, collapse in this way, and have to be remolded. To avoid handling, the pipe is stacked on end a few feet from the place of mixing, the form being moved as the yard fills with pipe. One crew of four men can make about 250 joints or 500 lin. ft. of pipe a day.

**Engineering-Contracting*, Dec. 4, 1907.

As soon as hard enough, the pipe is turned end for end, and is then kept wet for several weeks before being laid. The coating of neat cement on the inside is applied with a short whitewash brush, and is a small item in the cost. In laying, the trench is carefully finished to grade in order to have the joints close nicely, and the ends are well wet with a brush. The mason then spreads mortar, mixed 1 to 2, on the end of the pipe, and lays a bed of mortar at the bottom of the joint. He then jams the section into place, and swabs out the inside of the joint with a stiff brush, to insure a smooth passage for the water. A band or ring of mortar is spread round the outside of the joint as an additional reinforcement. One barrel of cement will joint about 300 sections of pipe. The materials cost as follows: Portland cement, per bbl., \$4.45; labor, per day, \$2; foremen, per day, \$2.50 to \$3; hauling, per load mile (1 cu. yd.), 20 cts.; sand, free at pit; water, free.

The pipe was all of a 1:4 sand and cement mortar, and the amount of cement in one foot of pipe is arrived at by assuming as in Gillette's "Hand Book of Cost Data" that where the sand has voids in excess of the cement used, the mortar will occupy 1.1 times the space of the dry sand, which yields the following formula: Where—

c = cost per bbl. of cement, or \$4.45.

π = cu. ft. in one bbl. (taken at 3.5 here).

s = ratio of sand to cement, or 4.

d = inside diameter in inches.

t = thickness of pipe in inches.

l = length of pipe considered, or 1 ft. here.

Then:

$$\text{Cement-cost per foot} = \frac{c \times l \times \pi \times (dt + t^2)}{\pi \times s \times 1.1 \times 144}$$

$$\text{which gives here} = \frac{4.45 \times 1 \times 3.142 (dt + t^2)}{3.5 \times 4 \times 1.1 \times 144}$$

$$= 0.00621 (dt + t^2).$$

This gives the following cement costs per lineal foot:

Diameter, ins.	Thickness, ins.	Cost per foot.
6.....	1 1/4	\$0.0571
8.....	1 1/4	0.0730
10.....	1 3/8	0.0938
12.....	1 1/2	0.1278

The sand cost is based on 15 cts. per cu. yd. for loading, and a haul of two miles of 1 cu. yd. to the load, making five trips per day, at \$4 for man and team. It bears a constant ratio to cement cost, being 11.2% of the cement cost. The labor cost of making is based on the foreman's estimate that a foreman, tamper, mortar mixer, and water man should finish 250 joints a day of 6 or 8-in. pipe. For the 10 and 12-in. pipe, the labor is assumed to be greater in proportion to the material. The foreman is taken at \$3, one man at \$2.50 and two at \$2. The cement for painting the inside is neglected. Hauling the pipe to place is taken at twice the cost of hauling the

sand per mile, and a haul of 4 miles is assumed. The cost of laying is based on a foreman's estimate of 2 cts. per foot for trench, and that one man to lay, one man to plaster the joints, one helper and one man to backfill will lay 600 ft. per day of 6 or 8-in. pipe. The larger sizes are assumed to cost more in proportion to their material.

These various costs give the following results for small size pipe as made and laid at Irrigon, Ore., for the Oregon Land & Water Co.:

	Cost per foot for—			
	6-in. pipe.	8-in. pipe.	10-in. pipe.	12-in. pipe.
Cement	\$0.057	\$0.073	\$0.089	\$0.128
Sand	0.006	0.008	0.011	0.014
Labor	0.019	0.019	0.026	0.034
Hauling	0.024	0.032	0.044	0.056
Laying	0.024	0.024	0.032	0.042
Trench	0.020	0.020	0.020	0.020
Totals	\$0.15	\$0.18	\$0.21	\$0.29

The above costs show that the pipe in place costs about twice as much as pipe in the yard, even with cement at \$4.45, and illustrates the danger of accepting cement manufacturers' estimates without examining local conditions, especially as to handling.

(For further data on cement pipes, see the sections on Waterworks and on Sewers.)

Cost of Concrete Pipe.*—The following estimates of cost of concrete pipe manufactured by force account on the Shoshone Project are based on the results of five days' work in November, 1907. The cost of cement was \$3.05 per bbl., of sand about \$1.40 per cu. yd., and of labor \$5 per day for 1 foreman, \$3 per day each for 2 men and \$2.75 per day each for 2 men. Plant depreciation and administrative expenses are not included in the unit costs given. The concrete was made of 1 part cement and 3 parts sand. The size and the thickness of the pipe, the weight and the unit cost per linear foot thereof and the number of linear feet manufactured in the five days are tabulated below:

Diam. Ina.	Thick. Ina.	Wt. per lin. ft. Lbs.	No. ft. made	Cost per ft.
12	1½	56	144	\$0.25
18	1¾	94	248	0.37
24	2	143	56	0.57
36	3	366	54	1.16

Cost of Cement and Concrete Pipes and Sewers, References.—See the sections on Waterworks and on Sewers. See Chapter XXI, Methods and Cost of Aqueduct and Sewer Construction in Gillette and Hill's "Concrete Construction."

Cost of a Band Stand.—Mr. W. F. Creighton gives the following data:

The band stand was built much like a mushroom, the roof being 32 ft. in diameter, supported by a central post. The floor was concrete also. The concrete was a 1:2:4 stone dust, ¾ to 1½-in. broken stone mixture. It was mixed by hand and hoisted in wheel-

*Engineering-Contracting, March 18, 1908.

barrows by means of a gallows frame and snatch block operated by a mule. The forms for the shaft and underside of the stand consisted of steel plates nailed to vertical radial ribs built to the designed curve. These ribs were made of 2-in. lumber. Toward the upper ends where the radial spread between ribs was largest cross-struts were built between ribs. The outer ends of the ribs were supported by staging; they were also braced at the tangent points on the center column or stem. The amount of concrete was 80 cu. yds. and it cost as follows:

Materials.	Total.	Per cu. yd.
119 bbls. cement at \$2.65.....	\$ 319.95	\$ 3.95
40 cu. yds. stone dust at \$1.10.....	44.00	0.55
80 cu. yds. broken stone at \$1.10.....	88.00	1.10
5,500 lbs. reinforcement.....	229.00	2.86
2,500 ft. B. M. lumber and shopwork..	76.21	0.95
Total	\$ 754.16	\$ 9.41
Labor.		
Mixing and placing concrete.....	\$ 171.00	\$ 2.14
Bending and placing steel.....	40.00	0.50
Falswork and wood forms.....	113.90	1.43
Steel forms (labor and material).....	164.00	2.05
12-in. pipe (furnishing and erecting)...	86.25	1.08
Unloading and hauling stone ¼ mile..	60.00	0.75
Finishing	12.00	0.16
Excavating	5.00	0.06
Total	\$ 652.15	\$ 8.17
Superintendence	42.00	0.53
Foreman	39.00	0.48
Total	\$ 81.00	\$ 1.01
Grand total	1,487.31	18.59

Cost of Sylvester Wash and Sylvester Mortar.—Mr. W. C. Hawley is authority for the following: A covered concrete clear water well of the Apollo Water-Works Co. leaked, so it was plastered with a Sylvester mortar. A light-colored soft soap was dissolved in water, $1\frac{1}{4}$ lbs. soap to 15 gals. of water. Then 3 lbs. of powdered alum were mixed with each bag of cement. The mortar was 1:2. Two coats of this plaster were applied to the dry walls, giving a total thickness of $\frac{1}{2}$ in. Leaking was thus stopped completely. The cost was:

2 lbs. soap (with 24 gals. water), at $7\frac{1}{2}$ cts.....	\$0.16
12 lbs. alum, at $3\frac{1}{2}$ cts.....	0.42
Total	\$0.57

Or 57 cts. for soap and alum per barrel of Portland cement.

In repairing the bottom of a reservoir lined with 4 to 6 ins. of concrete which leaked, a Sylvester wash was used. The soap solution was $\frac{1}{4}$ lb. of Olean soap to 1 gal. of water, and the alum solution was $\frac{1}{2}$ lb. alum to 4 gals. water; both well dissolved, soap solution being boiled. On the clean dry concrete the boiling hot soap solution was applied, 24 hrs. later the alum wash; 24 hrs. later the soap wash; 24 hrs. later the alum wash. Two men applied the solutions, using whitewash brushes, while a third man carried pails of the solution. In making the soap solution 2 men attended 4

kettles, 1 man kept up fires, 2 men carried solution to men applying it. The alum solution required fewer men, being made cold in barrels. After applying the second soap wash to the concrete slopes, men had to be held by ropes to keep from slipping. The rope was placed around two men, who started work at top of the slope, a third man paying out on the rope. The work was done in $8\frac{1}{2}$ days, and the cost as follows:

Labor.	
1,140 hrs. labor at 15 cts.....	\$171.00
83 hrs. foremen at 30 cts.....	24.90
83 hrs. waterboy at 6 cts.....	4.98
Add for supt. 15%.....	30.13
Total labor.....	\$231.01
Materials.	
900 lbs. Olean soap at $4\frac{1}{2}$ cts.....	\$ 39.00
210 lbs. alum at 3 cts.....	6.30
6 whitewash brushes (10-in.), at \$2.25.....	13.50
5 stable brushes, \$1.25.....	7.50
Total materials.....	\$ 66.30
Total labor and materials.....	297.31

This covered 131,634 sq. ft., hence the cost of the two coats of soap and alum was \$2.26 per 1,000 sq. ft., or 0.23 ct. per sq. ft. All leaks but one from a slight crack were stopped.

The concrete lining of a new reservoir near Wilmerding was waterproofed by using caustic potash and alum in the finishing mortar coat. The stock solution was 2 lbs. of caustic potash, and 5 lbs. of alum to 10 qts of water. This was made in barrel lots, from which 3 qts. were taken for each batch of finishing mortar, which consisted of 2 bags of cement mixed with 4 bags of sand; a batch of mortar covered an area 6 ft. x 3 ft. 1 in. thick. The extra cost of this waterproofing was:

100 lbs. caustic potash at 10 cts.....	\$10.00
70 lbs. caustic potash at 9 cts.....	6.30
260 lbs. alum at $3\frac{1}{4}$, $3\frac{3}{4}$ and 4 cts.....	34.32
60 hrs. mixing at 15 cts.....	9.00
Freight, express and hauling.....	11.50
Total for 74,800 sq. ft.....	\$71.12

So the cost was 95 cts. per 1,000 sq. ft., or less than 0.1 ct. per sq. ft. Hence the cost was less than by using Sylvester's wash and the result was better, for with Sylvester's wash the penetration is only $1/16$ to $1/8$ -in. It was found that if less than 2 parts of sand to 1 part of cement were used the mortar cracked in setting. Clean sand was imperative as any organic impurities soon decomposed, leaving soft spots. Do not use an excess of potash; a slight excess of alum, however, does not decrease the strength of the mortar.

Cost of Waterproofing With Tar Felt and Asphalt.*—The following data relate to the cost of waterproofing the concrete on the Long Island R. R. subway:

The specifications for the waterproofing will be found in Gillette and Hill's "Concrete Construction."

**Engineering-Contracting*, July 18, 1906.

During the year 1903 there were laid 9,056 sq. yds. of this waterproofing on the roof of the subway. The labor cost of placing the two layers of felt and the three coats of tar pitch was as follows: 204 days labor at a cost of \$498 (or an average of \$2.41 per day) for the 9,056 sq. yds., which is equivalent to $5\frac{1}{2}$ cts. per sq. yd. for the labor. Since this is for two layers of felt, the labor cost was $2\frac{1}{2}$ cts. per sq. yd. of single layer, which is a high cost as we shall see presently.

The labor cost of mixing and placing the 1-in. layer of cement mortar over the felt was as follows: It required 589 days, at a cost of \$1,306 (or an average of \$2.22 per day) to place this 9,056 sq. yds. of cement plaster, which is equivalent to $14\frac{1}{2}$ cts. per sq. yd.

The total cost of labor for the two layers of tar felt and the layer of cement mortar was, therefore, 20 cts. per sq. yd. on this Long Island R. R. work.

For comparison, we will now repeat some of the cost data given in our February issue, relating to the New York Subway. On the New York Subway, the specifications were somewhat similar, except that no mortar coat was specified. The roof of the New York Subway was waterproofed with four layers of asphalt felt and asphalt. The floor of the subway made two layers of asphalt felt placed between two layers of concrete. We may say, therefore, that the average number of layers of felt used in waterproofing the New York Subway was three. The records of cost for this work were kept in terms of one layer of felt, so that it is necessary to multiply the following costs by three in order to get the cost of the three layers. For estimating the quantities of materials used, the following rules were deduced:

Reduce the area to square yards, and add 15% for laps, to obtain the square yards of asphalt felt per single layer.

Multiply the square yards by 0.37 to get the number of gallons of asphalt per single layer of felt.

Where brick are laid in asphalt, allow 650 brick per cu. yd.; and multiply the number of cubic yards of brick by 0.8 to get the number of tons of mastic.

The cost of some 98,000 sq. yds. waterproofing on the New York Subway, was as follows per single thickness of felt:

	Per sq. yd. (single). cts.
1.11 sq. yds. asphalt felt at $4\frac{1}{2}$ cts.....	5
0.37 gal. asphalt at 12 cts.....	$4\frac{1}{2}$
Labor	$5\frac{1}{2}$
Total	15

This is for one thickness of felt, so that for 3 thicknesses the cost would be 45 cts. per sq. yd. for labor and materials. Both the labor and materials were high in cost. The labor was high because the men were poorly supervised. There were 2 waterproof "foremen" at \$3 per 8-hr. day, and 7 waterproofer (laborers) at \$1.50 per day, so that the average wage was \$1.83 per day. The "foremen" were skilled waterproofer who worked with the gang.

The material was high priced, because asbestos felt dipped in asphalt was specified. The felt weighed 10 lbs. per 100 sq. ft.

To illustrate how unusually inefficient the waterproofers were, the following records are given. These records were kept by the writer, and relate to the waterproofing of brick walls. The wall was built up one brick thick (4 ins.), and was then waterproofed with three layers of tar felt mopped with tar pitch. The layers lapped on one another like the shingles of a roof, the exposed face of each layer being 1 ft. wide. Three men were engaged in the work: one man melted and carried the tar in buckets, one man mopped it on, and the third man laid the tar felt. The bricks were first mopped with tar, then the felt was laid on and mopped with tar; then a second layer of felt, and so on. The two men mopping and laying felt easily averaged 120 sq. yds. in 8 hrs. Since this was 3-layer work, the men averaged 360 sq. yds. of single layer per day. Skilled roofers were employed placing and mopping the felt at \$2.75 a day, and the laborer helping them received \$2 a day, so that the gang received \$9 for 360 sq. yds., or $2\frac{1}{2}$ cts. per sq. yd., wages averaging \$2 per 8-hr. day per man engaged. As a matter of fact, only one skilled man was needed; and, had there been enough work to do, one laborer could have melted and delivered enough tar for two gangs. It usually requires about $\frac{1}{2}$ gal. tar per layer of felt, which would mean 120 gals. of tar per day per gang of two men laying. Tar weighs about as much as water, or $8\frac{1}{2}$ lbs. per gal., hence 1,000 lbs. tar would be used by the gang of two men in a day. [In the Waterworks section of this book will be found the cost of waterproofing a large reservoir. This work was done on a large scale. Two men heated and delivered the asphalt to one man who spread it with a mop made of twine. The man with the mop spread 5,000 lbs. of asphalt per day of 10 hrs., covering an area of 1,000 sq. yds., which is equivalent to 0.6 gal. per sq. yd. Since two men boiled and delivered the asphalt, each of these two men averaged 2,500 lbs. or 300 gals. per day. It took one cord of wood to boil about 20,000 lbs., or 2,400 gals., from which it will be seen that the item of fuel is practically negligible.]

While men engaged in mopping tar or asphalt over layers of felt cannot be expected to accomplish as much work as men mopping tar over an extended area, still comparisons such as the above are valuable because they show where money may be saved. In this instance the comparison shows that a man boiling and delivering tar is not kept busy unless he is handling at least 300 gals. a day.

When one man is mopping on the tar and a second man is laying the felt, one of the two is usually idle while the other is busy. Provided each man works with great rapidity when he is actually working, very little time is really lost; but, if left to themselves, the workmen will take a very slow gait, and thus more than double the cost.

Finally, unless labor unions interfere, there is really no need of high-priced labor on work of this character. Common laborers can be used for all work except laying the felt, and, even in that work,

a grade of skill only slightly above the average of the common laborer is needed.

As for the felt itself, there is no necessity of anything better than a good grade of tar felt weighing about 15 lbs. per 100 sq. ft., and costing about 1½ cts. per lb., or 3 cts. per sq. yd. We are speaking now of felt for waterproofing, not of felt for roofing that is exposed to the air.

The writer has seen felt that had been laid in coal tar pitch; and, after 33 years service, it was as flexible as the day it was laid. This felt had been used to waterproof the outside of the masonry arch forming the roof of the Park Avenue Tunnel, N. Y. C. & H. R. Ry., built in 1872. The felt was laid in two layers and covered with 2 or 3 ft. of earth. Wherever it had been covered it was in perfect condition when taken out in 1904. Mr. A. B. Corthell, Terminal Engineer, New York Central Ry., New York City, has specimens of this old felt. As the process of making coal gas has not changed in the last 30 years, it is obvious that as good coal tar pitch is to be had to-day as ever. There are petroleum residues that are sold as pitch which are not of a durable nature, and such products have, perhaps, given a black eye to pitch in general.

Let us see what two layers of tar felt can be laid for:

	Two layers per sq. yd. cts.
3 sq. yds. tar felt at 3½ cts.....	10
¾ gal. asphalt at 12 cts.....	9
Labor (\$2 a day).....	5
Total for 2 layers felt.....	14

This is equivalent to 7 cts. per sq. yd. of single layer. In the above estimate, 12% has been added to the price of the tar felt to allow for laps. The labor is assumed at a lower rate than would probably be paid in cities where labor unions control such work, but it is as high as would be paid outside of cities.

Cost of Waterproofing Batteries With Coal Tar and Sand.*—Coal tar and sand was used in waterproofing the superior crests of three batteries at Fort Mott, N. J. The tar was applied hot and was spread over the concrete surfaces with rubber squeegees and then sanded. Joints were filled with hot tar. A surplus of sand was put on and left for a few days and was then swept off. Two coats were put on over the traverses and one coat over the parapets. The total surface covered, two coats, was 14,700 sq. ft., and one coat, 19,800 sq. ft.; 21½ bbls. of coal tar were used, or about 1 bbl. per 2,279 sq. ft. The tar cost \$4.25 per bbl. delivered, and the cost of the waterproofing, including materials and labor, was \$0.0074 per sq. ft., one coat. In two of the batteries practically all percolation was stopped.

Cost of Waterproofing Bridge Floor, Pennsylvania Ry.†—Mr. A. L. Bowman is author of the following:

**Engineering-Contracting*, April 3, 1907.

†*Engineering-Contracting*, Nov. 4, 1903, p. 290.

Method of Applying Waterproofing.—First. The steel floor plate was thoroughly cleaned and painted with one coat of red lead and oil.

Second. A filler of mastic asphalt was placed along the webs of the girders.

Third. Five layers of Hydrex felt cemented together with Hydrex compound were then put on the floor plate and carried as far as possible up under the flashing angles, which were fastened along the webs and around the stiffeners and the ends of the girders. The felt was not cemented to the floor plate but was thoroughly cemented to the webs of the girders.

Fourth. A layer of brick laid flat was then placed on the felt in a hot layer of compound, the brick being laid lengthwise of the bridges.

Fifth. The joints between the brick were thoroughly poured with compound and the whole surface mopped with compound.

Sixth. The stone ballast ties and rails were then placed on the bridge (Fig. 11).

Labor and Time on Waterproofing After Steel Work Was Erected.

Fig. 11.—Waterproof Bridge Floor.

—The skilled and common laborer employed per square (100 sq. ft.) was as follows: Foreman, 1.66 hra.; waterproofers, 11.71 hra.; laborers, 7.75 hra. The overtime to complete a floor of 750 sq. ft. was 1.4 days of 10 hra. The best time for one track, 750 sq. ft., was one day of 10 hra.

Cost.—The cost of waterproofing materials per square foot of floor surface was 20% cts. The cost of labor per square foot was 10% cts. **Materials Per Square (100 sq. ft.).**—Brick, 440; Hydrex compound, 41.2 gals.; Hydrex felt, 1 46 rolls (400 sq. ft. per roll).

Result.—The bridges are watertight with the exception of a few points immediately over columns.

During a severe storm the water leaks down to some extent, between the main and side walk girders. It seems impossible to keep these points absolutely tight.

The vibration and reflection of the girders break the bond of any material which is placed between the ends of the girders. From a close observation of these bridges it seems impossible to make the compound adhere to the steel for any length of time, due to the vibration of the steel work and the hardening of the material during cold weather.

It is necessary to protect the edges of the waterproofing along the girders from water running down behind after the waterproofing has broken loose. This was done by means of the flashing angles referred to above.

No attempt should be made to fit the brick along the web of brackets, the brick being simply shoved as tight as possible and then the openings poured with the compound. Afterward the opening under the flashing angles should be filled with concrete to keep the edges of the felt from curling over.

The felt was carried well over and down the back walls, drainage being had by putting the bridges on a grade and allowing the water to run behind the abutments, which were drained by pipes running through the abutments to the gutters.

Cost of Waterproofing, References.—For further data on this subject consult the index under "Waterproofing." See Chapter XXV, *Methods and Cost of Waterproofing*, in Gillette and Hill's "Concrete Construction."

Cost of Removing Efflorescence With Acid.—Efflorescence, or "whitewash," on a concrete bridge at Washington, D. C., was removed by using hydrochloric (muriatic) acid and common scrubbing brushes; 30 gals. of acid and 26 scrubbing brushes were used to clean 250 sq. yds. of concrete. The acid was diluted with 4 or 5 parts water to 1 of acid; and water constantly played with a hose on the concrete while being cleaned to prevent penetration of the acid. One house-front cleaner and 5 laborers were employed, and the total cost was \$1.50, or 60 cts. per sq. yd. This high cost was due to the difficulty of cleaning the balustrades. It is thought that the cost of cleaning the spandrels and wing walls did not exceed 20 cts. per sq. yd. The cleaning was perfectly satisfactory. An experiment was made with wire brushes without acid, but the cost was \$2.40 per sq. yd. The flour removed by the wire brushes was found by analysis to be silicate of lime. Acetic acid was tried in place of muriatic, but required more scrubbing.

For further data on cleaning with acid, see the section on *Stone Masonry*. Consult the index under "Masonry, Cleaning."

Cost of Bush-Hammering Concrete.—Mr. C. R. Neher states that a concrete face can be bush-hammered by an ordinary laborer at the rate of 100 sq. ft. in 10 hrs., at a cost of 1½ cts. per sq. ft. The cost of forms saved by using rough lumber goes a long way toward covering the cost of bush-hammering. The front of the Dakota elevator in Buffalo, N. Y., was bush-hammered. Bush-hammering removes stains due to efflorescence.

Ransome says that bush-hammering concrete costs 1½ to 2½ cts. per sq. ft., wages of common laborers being 15 cts. per hr. The Ransome Concrete Mch. Co., Dunellen, N. J., make a toothed ax especially designed for bush-hammering concrete.

The walls of the Pacific Borax Co. factory at Bayonne, N. J., were dressed by hand at the rate of 100 to 200 sq. ft. per day; but most of the dressing was done with a pneumatic hammer, with which a man was able to dress 300 to 600 sq. ft. per day.

At the Harvard Stadium I timed men working with pneumatic hammers, using a tool like an ice chopper with a sawtooth cutting blade. One man dressed a wall at the rate of 50 sq. ft. per hr., but I was told that 200 sq. ft. was a 10-hr. day's work. I am inclined to think, however, that much more than 200 sq. ft. a day could be averaged. Common laborers are used for this sort of work.

For the cost of operating pneumatic hammers, when gasoline is used for power consult the index under *Pneumatic Hammer*.

A common method of finishing concrete surfaces is to remove the forms before the concrete is very hard, say in 24 hrs., and scour the surface with a wire brush to as much as half the depth of the pebbles of gravel or stone. This can be done for 7 cts. per sq. ft.

The average cost of bush-hammering the concrete blocks for the Connecticut Ave. Bridge, at Washington, was 26 cts. per sq. ft. The work was done by stonemasons who received \$4 per day, which partly accounts for the high cost. Moreover a very high grade of work was required. The cost ranged from 14 cts. per sq. ft. to 47 cts. per sq. ft., and is given in detail in Gillette and Hill's "Concrete Construction."

Cost of Excavating Concrete.—Mr. Ernest W. Shader gives the following. A hole was cut through a concrete dam 10 yrs. old at Ithaca, N. Y. The concrete was crushed shale, and a mixture of natural and Portland cement had been used. The concrete was soft but tough. A pneumatic plug drill was used, and the concrete was chipped out with flat chisels $1\frac{1}{2}$ in. wide. A narrower chisel was not so good, and plug and feathering was impracticable because the drill would stick in the hole. (Perhaps a water jet would have overcome this difficulty.) Two Italian laborers alternated in holding the pneumatic machine, and they averaged exactly 1 lin. ft. of hole $5\frac{1}{2}$ ft. diameter per 9-hr. day, for 16 days. The air pressure was 70 lbs. This is equivalent to $22\frac{1}{2}$ cu. ft., or 0.83 cu. yd. per day by two men with a pneumatic machine.

A liberal supply of sharp chisels was provided. The chisel was sunk into the concrete until the blows of the hammer caused a piece to chip off. The time per chip ranged from a few seconds to 10 minutes. When the men become experienced they drove two or three chisels along a line and thus wedged off as much as $\frac{1}{2}$ cu. ft. of concrete. This worked well when the lower part of the hole was advanced ahead of the upper part.

For comparison with the data above given, see Gillette and Hill's "Concrete Construction," p. 107, where it is stated that it took a quarryman 5 days to chip off 1 cu. yd. of concrete from the face of a concrete abutment that projected too far. Also see p. 652, etc., of the same book for methods and cost of blasting concrete.

For cost of excavating a concrete pavement base see the section on *Roads and Pavements*.

Cross References and References.—In other sections of this book will be found data on concrete costs, for which see the index under *Concrete*. The cost of quarrying and crushing stone for concrete

will be found in the section on Rock Excavation. In estimating the cost of forms the data in the section on Timberwork will be of aid.

The following books on concrete cover different parts of this great subject:

"Concrete Construction—Methods and Cost," by Gillette and Hill, is a 700-page treatise devoted solely to the methods and cost of concrete and reinforced concrete work of every variety. While intended primarily as a treatise for contractors and for engineers engaged in actual field work, it will aid the designer also if he aims to design and specify construction on which low bids will be assured. I cannot too often repeat the statement that no designer is thoroughly competent unless he has a thorough knowledge of every detail of actual cost.

"Concrete and Reinforced Concrete Construction," by Homer A. Reid, M. Am. Soc. C. E., is a 900-page treatise written primarily for the designing engineer and the engineering student, but it is full of illustrations of forms, arch centers, and text matter of value to the contractor also. There is, in my opinion, no single book that so well covers both theory of concrete design and practice of construction, as does this book, when the whole field of concrete is considered. The field, however, is so great that in addition to one such treatise covering the whole field, most engineers and contractors need special treatises on special branches, such as the one by Gillette and Hill, above mentioned, and such as the others mentioned below. Reid's work contains more than 700 drawings and half-tones. A statement of this number alone gives some idea of the wide scope of the work.

"Engineers' Pocketbook of Reinforced Concrete," by E. Lee Heidenreich, contains 374 pages of tables and data for the engineer who is designing reinforced concrete structures. I know of no book that is its equal for this purpose. The author is an experienced designer, indeed, one of the first American civil engineers to make reinforced concrete designing a specialty.

"Reinforced Concrete, A Manual of Practice," by Ernest McCullough, is a book which presents the subject of designing reinforced concrete in the simplest manner possible; also the principles of safe and good construction are set forth in an equally lucid manner. The author has had a very extensive experience in concrete work both as an engineer and as a contractor.

"Theory and Design of Reinforced Concrete Arches," by Arvid Reuterdaahl, is self-explanatory in its title. The author's aim has been to present the theory in a perfectly complete form, leaving no gaps to be supplied by reference to other books.

"Concrete Bridges and Culverts," by H. G. Tyrrell, is a 272-page treatise in which the author presents the formulas to be used without giving the mathematical derivation, thus making it a very useful book for any engineer, other than the student of engineering. The author gives many tables of dimensions for standard railway and highway bridges and culverts, also tables of quantities and estimates of cost.

"Practical Cement Testing," by W. P. Taylor, is the work of a practical cement tester, and I think that in that respect it is unique among books or parts of books on cement testing. It covers the subject in its 320 pages.

"Concrete Inspection," by Charles E. Hill, is a pocket-size book of 186 pages, in which no extraneous matter is contained. It is a manual on cement inspection written by the author of the first American treatise on reinforced concrete construction, and an engineer who has a wider acquaintance with the literature of cement and concrete than anyone I have met. My close association with Mr. Hill in the production of our joint book, and in our editorial work, is the basis for the foregoing statement, in the breadth of which I may be unwittingly doing injustice to others who have attempted to keep pace with the literature on cement and concrete.

"Diagrams for Designing Reinforced Concrete Structures," by G. F. Dodge. The diagrams are plotted on logarithmic paper, and are so devised that results are read direct for any condition that occurs in ordinary practice.

Summary.—In this connection I may say that not since engineering began has there ever been a subject that has brought forth, in so short a time, so many articles, scientific papers, and books as have appeared on this subject of cement and concrete. This literature has had a profound influence upon the growth of the cement and concrete industry. Had it not been for the extensive literature on the subject, engineers would have been a generation longer in acquiring sufficient knowledge of concrete and its economic merits to lead them to the extensive use that concrete now enjoys. Authors of books and editors of, and contributors to, technical periodicals have been the educators who have made the use of concrete well nigh exclusive for some classes of construction, and a large factor in nearly every class that can be mentioned. In this process of education their work has been supplemented by that of intelligent manufacturers of cement and of concrete machinery, likewise to a degree never before witnessed in the technical advertising world. So, in concluding my references, I can do no better than to urge upon every engineer and contractor the importance of securing, and keeping up to date, a small library of the catalogs of manufacturers of cement and of concrete machinery, tools and appliances.

SECTION VII.

WATER - WORKS.

Definitions.—**Backfill**, the excavated earth that is put back into a trench.

Ball Joints.—A cast iron pipe with special ends that permit of deflection of the pipe line, after the lead has been poured, is said to have "ball joints" or "flexible joints."

Bell.—The flaring end of a cast iron pipe, as distinguished from the smaller end, or spigot, which fits into the bell.

Bell Holes.—After cast iron pipe are placed in a trench, it is customary to enlarge the trench somewhat by digging away the bottom and sides around the bells of the pipes, at each joint. The excavation thus made is called a bell hole.

Bend.—A short curved length of pipe. Bends are sold as "specials" at a price higher than for ordinary pipe. See Frye's "Civil Engineers' Pocketbook" for dimensions and weights of bends and other specials.

Brace.—A horizontal timber across a trench. Also an iron pipe with a telescopic end is called an "extensible brace."

Bracing.—The timber used to support the sides of a trench.

Branch.—A Y-shaped piece of pipe sold as a "special."

Calk.—To fill the joints of a pipe to prevent leakage. In cast iron pipe, yarn is first inserted; then lead is poured into the joint. The operation of driving the lead home is often called "calking," although the entire process of making a joint water tight is also termed calking.

Corporation Cock.—A cock or valve joining the main water pipe to the service pipe, so that the water may be shut off from any consumer.

Depreciation.—The loss of value due to lost life. If the straight line formula of depreciation is used, the annual depreciation is the reciprocal of the life in years; thus a life of 20 years gives a depreciation of 5% per annum. Depreciation should not be confused with current repairs and renewals of parts.

Duty.—A term applied to pumping engines to express amount of work done. The Am. Soc. M. E. definition is number of foot pounds of work done by the expenditure of 1,000,000 B. T. U. (British thermal units). The duty therefore depends upon the character of engine employed.

Dynamic Head.—The actual head of water in a pipe plus the friction head.

Electrolysis.—The destruction of a metal due to chemical action developed by an electric current.

Faucet.—The flaring or "bell" end of a cast iron pipe.

Filter.—A "slow sand filter" consists of a large "filter bed" of sand, underlaid with gravel or broken stone, through which water passes and enters the drains that lead off the clear water. A "mechanical filter" (often called an "American filter"), consists of a small tank containing a bed of sand through which the water passes, after having been dosed with some coagulant, such as lime. The sand is cleaned at short intervals by reversing the current of water.

Flume.—A trough for carrying water; usually made of lumber.

Forebay.—The reservoir from which water passes immediately to a water wheel.

Friction Head.—The head of water necessary to overcome the friction developed by passing through a pipe.

Frost Box.—A box surrounding a waterpipe and containing some heat insulator, like mineral wool, excelsior or sawdust, to prevent the water from freezing.

Gallon.—The U. S. gallon contains 8 pints, or 4 quarts, or 231 cu. ins., or 0.13368 cu. ft., or 3.7855 litres, or 0.03175 liquid barrels. A cu. ft. contains 7.48052 ($7\frac{1}{2}$ nearly) gallons. A gallon of water, at 59.2° F., weighs 8.33333 ($8\frac{1}{2}$ nearly) lbs.; or 1 lb. of water = 0.12 gals. British Imperial gallon = 1.20032 U. S. gallons.

Gate.—A stop valve placed in water mains, usually at intervals of 300 to 500 ft., to shut off water from any section during repairs, etc.

Infiltration.—The flow of ground water into a well; or the flow of water through the ground, from a nearby lake or river, into a gallery.

Mains.—The system of large water pipes that supply the smaller laterals or service pipes.

Mineral wool, or slag wool, is fibrous slag, often used for packing around water pipes to prevent freezing.

Miners' Inch.—Usually the amount of water that will flow, in 24 hrs., through an opening 1 in. square in a plank 2 ins. thick, under a head of 6 ins. measured from the upper edge of the opening. Such an opening will discharge 11.625 gals. or 1.554 cu. ft. per minute, or 0.026 cu. ft. per sec. This is the Colorado miners' inch. The California miners' inch is 0.02 cu. ft. per second.

Oakum.—Material obtained by picking to pieces old hemp rope.

Packing.—Oakum with long fibres twisted into strands and used in filling pipe joints.

Pouring Clamp.—A device often used instead of the ordinary clay "roll" for holding in the molten lead used to form a joint in a cast iron pipe.

Puddle.—A mixture of gravel and clay, wet and compacted, and so deposited as to prevent leakage through more porous soil.

Ranger.—A long horizontal timber along the side of a trench, against which the "braces" abut.

Reducer.—A short funnel shaped section of pipe.

Roll.—A roll of clay placed temporarily around a pipe to retain the molten lead poured into the joint.

Runner.—Same as ranger.

Service Pipe.—A short lateral pipe of small diameter, usually of wrought iron or lead, extending from a "main" to a house, store, or the like.

Sheeting, or Sheathing.—Plank used to face the sides of a trench to prevent its caving in. When the planks are sharpened and driven, they are called sheet piles.

Shoring.—Braces used temporarily to support any structure while excavating near it. Also used to designate the braces and rangers in a trench, for which it is preferable to use the term bracing.

Skeleton Bracing.—A system of braces and rangers, without any sheeting; or merely a system of braces abutting against short lengths of plank.

Specials.—Bends, branches, tees, crosses, reducers, and all similar castings, other than the regular 12 ft. lengths of pipe, are called specials, and are sold (by the pound) at a higher price than the regular pipe.

Spigot End.—The small end of a cast iron pipe as distinguished from the bell end.

Stand Pipe.—A high, vertical pipe of large diameter holding a supply of water.

Ton.—Cast iron pipe is sold by the ton of 2,000 lbs. Pig iron is sold by the ton of 2,240 lbs.

Yarn.—Same as packing.

Cost of Complete Water Works Systems.—For purposes of rough preliminary estimates of cost, and more frequently for purposes of comparison and generalization, an engineer often wishes to know the approximate first cost of a complete waterworks system for a city or town of given size.

Table I is taken from a report by Mr. Paul Hansen, Assoc. M. Am. Soc. C. E., Assistant Engineer Ohio State Board of Health, and printed in *Engineering-Contracting*, Sept. 15, 1909. The author has the following to say about the table:

"The matter that most interests the taxpayer in connection with the installation of public water supplies is cost, and to this end I have prepared a table giving unit costs for construction and operation. These figures are necessarily very general, as they cover a wide range of conditions. They, however, are suggestive and give an approximate idea of expenditures involved."

Average Cost of Constructing and Operating Water Works in Massachusetts.—Mr. Freeman C. Coffin gives the following costs of constructing and operating 39 water works systems in Mass., for the year 1893. The systems were all owned by the municipalities, and in every case the water was pumped. Total cost of operation, including an allowance of 4% for interest on the first cost of the water works system, and 1½% for depreciation, averaged \$115 per million gallons; the minimum cost being \$65 in one city; and the maximum cost being \$257. The average per capita cost was \$2.58

HANDBOOK OF COST DATA

TABLE 1.—AVERAGE COST OF CONSTRUCTION AND OPERATION OF PUBLIC WATER SUPPLIES.

Range of Population.	Average total cost of installation.	Average cost of per capita.	Maximum cost per capita.	Minimum cost per capita.	Average cost per person using.	Average total an- nual operating expenses.	Average annual operating ex- penses per cap- ita.	Av. annual opera- ting expenses per person using.	Minimum annual operating ex- penses per cap- ita.	Max. annual opera- ting expenses per person using.
*Under 500	8,557	20.02	43.50	6.20	43.34	508	1.19	2.05	0.09	4.33
500 to 1,000	17,948	22.12	38.60	9.15	35.13	1,071	1.23	1.92	.49	5.30
1,000 to 2,000	32,442	18.31	32.50	14.00	29.90	1,677	1.52	2.38	.73	4.75
2,000 to 5,000	68,089	17.41	29.20	10.85	20.95	5,478	1.47	1.72	1.11	2.74
5,000 to 10,000	147,282	17.06	32.40	7.15	23.38	7,616	1.14	1.93	.76	3.08
10,000 to 20,000	443,280	21.50	45.50	10.00	23.50	18,327	.88	1.03	.51	2.27
20,000 to 40,000	667,200	18.30	32.70	8.71	22.90	23,750	.81	1.03	.55	2.41
†Over 40,000	7,962,000	27.99	43.30	11.50	33.90	338,360	1.01	1.36	.73	3.98

*Average of three communities.

†Average of ten communities.

per year; the minimum being \$1.25; and the maximum being \$5.62. The average daily per capita consumption was 62.3 gals.; the minimum being 23, and the maximum 227 gals. The water was pumped to an average height of 188 ft. dynamic head, which was about 10% greater than the static head. The coal consumption per million gallons was:

	Tons.
Minimum	0.75
Average	1.67
Maximum	7.00

The number of gallons pumped 1 ft. high (dynamic head) per pound of coal was:

Minimum	8,040
Average	56,844
Maximum	132,550

These cities may be divided into three groups: Group I, 22 cities under 15,000 population, and averaging 5,880 population (or consumers) on the pipe lines; Group II, 8 cities, 15,000 to 26,000 population, with an average of 21,250 on the pipe lines; and Group III, 8 cities, 31,500 to 85,000 population, with an average of 58,000 on the pipe lines.

The first cost of the water systems and the cost of operation, etc., for each of these three groups was as follows:

Group I.—Twenty-two cities, total population 129,300, on the pipe lines, consume 2,556,300,000 gals. per year, or 55 gals. per capita per day. The pumping plants consumed 6,500 tons of coal per year, or 2½ tons per million gallons. There were 472 miles of pipe line, and the cost of the water systems was \$4,720,000, or \$10,000 per mile of pipe line, including the cost of the pumping plants. There were 3,800 hydrants and 22,000 services; or 8 hydrants and 46 services per mile of pipe line. The cost of the water systems was \$365 per capita, or \$1,850 per million gallons annually consumed. The annual cost of operation, etc., was as follows:

	Total	Per Million Gals.
Pump station expense.....	\$ 49,200	19.30
Other expense of maintenance and operation..	58,400	22.80
Interest, 4% on \$4,720,000	188,800	74.00
Depreciation, 1½% on \$4,720,000.....	70,800	27.70
Total	\$367,200	\$143.80

In this group there were two cities where the cost was \$85 per million gallons, and there was one where the cost was \$252.

Group II.—Eight cities, total population 170,000, on the pipe lines, consumed 4,330,000,000 gals. per year, or 70 gals. per capita per day. The pumping plants consumed 5,339 tons of coal per year, or 1.23 tons per million gals. There were 425 miles of pipe line, and the cost of the water systems was \$6,200,000, or \$14,600 per mile of pipe line. There were 3,270 hydrants and 24,944 services, or nearly 8 hydrants and 60 services per mile of pipe line. The cost of the water systems was nearly \$370 per capita, or \$1,430

per million gallons annually consumed. The annual cost of operation was as follows:

	Total.	Per Million Gals.
Pump station expense	\$ 62,400	\$ 14.35
Other expenses	90,100	20.72
Interest 4% on \$6,200,000	248,000	57.04
Depreciation, 1½% on \$6,200,000	93,000	21.39
Total	\$493,500	\$118.50

Group III.—Eight cities, total population 448,500, on the pipe lines, consumed 10,750,000,000 gals. per year, or 66 gals. per capita per day. The pumping plants consumed 10,835 tons of coal, or 1 ton per million gallons. There were 675 miles of pipe line, and the cost of the water systems was \$16,300,000, or \$24,100 per mile of pipe line. There were 5,400 hydrants and 57,848 services, or 8 hydrant and 86 services per mile of pipe line. The cost of the water systems was \$353 per capita, or \$1,516 per million gallons annually consumed. The annual cost of operation was as follows:

	Total.	Per Million Gals.
Pump station expense	\$ 101,700	\$ 9.40
Other expenses	203,800	18.75
Interest, 4%	651,900	61.12
Depreciation, 1½%	244,500	22.57
Total	\$1,201,400	\$111.84

In this group there was one city of 44,000 population where the cost was only \$65 per million gallons, distributed thus:

	Total.	Per Million Gals.
Pump station expense	\$ 13,488	\$ 7.43
Other expenses	17,656	9.80
Interest, 4%	63,505	35.12
Depreciation, 1½%	23,851	13.14
Total	\$118,578	\$65.40

The coal consumption was 0.7 ton per million gallons, the dynamic head being 130 ft. (static head, 125 ft.). The cost of the system was \$351 per capita, or \$25,000 per mile of pipe line, or \$880 per million gals. consumed annually. This low first cost of plant per million gallons annually consumed is not due to superior design of plant, but to the large consumption of water, which was 112 gals. per capita per day. The per capita cost of water was \$2.69 per annum, which is above the average cost of this group.

Prices of Cast Iron Pipe.—Figure 1 shows the prices paid for cast iron pipe in cities and towns of the Central West, centering about Chicago, according to data collected by J. W. Alvord from various pipe contracts.

The prices of pipe are per ton of 2,000 lbs., and are from \$7 to \$10 above the prices for pig iron per ton of 2,000 lbs. in the same localities at the same time.

Prices of Cast Iron for Thirteen Years in Chicago.—The average cost of cast iron pipe per ton since 1894 to the Water Pipe Extension Division of the City of Chicago, Ill., has been as follows:

	Cost Per Ton.	Per Cent Variation in Cost.
1895	\$26.00	100
1896	23.00	88.4
1897	19.00	73.0
1898	25.00	96.1
1899	25.50	98.0
1900	25.50	98.0
1901	23.50	90.4
1902	28.00	107.7
1903	33.00	126.9
1904	30.00	115.4
1905	27.50	105.8

Cost in Dollars

Cost in Dollars

Fig. 1.—Prices of Cast Iron Pipe.

Weight of Cast Iron Pipe.—Pipe from 3 ins. to 60 ins. diameter is cast in 12-ft. lengths, that is in lengths that require 440 pipe lengths to lay a mile of pipe line, 1½-in. and 2-in. pipes are not often used, but when used are cast in shorter lengths.

Table Ia gives the approximate weights of cast iron pipes. It is customary to paint the weight of each pipe inside the pipe. As variations in single pipes of 5% from the listed weight are common, it is well to specify the maximum average variation allowable.

TABLE Ia.—WEIGHT OF CAST IRON PIPE.

Lead Required for Joints.—Billings states that the theoretical amount of lead required for joints in pipe used in Boston was given by the formula, $p = 2d$, in which p = lbs. of lead per joint, and d = diameter of pipe in inches. Actually, however, the following amounts were used:

Size of pipe. ins.	Actual lbs. lead per joint.	Theoretical lbs. lead. per joint.	No. of ft. pipe laid	Lbs. lead per ft. of pipe.
6	7.7	12	2,112	0.64
8	9.1	16	1,997	0.76
16	21.6	32	550	1.76
16	23.7	32	10,000	1.97

In the following examples of cost, data will be found as to the amount of lead used in different cases.

Items of Cost of Pipe Laying and Materials.—The expression, "cost of laying pipe," is usually used to include all labor costs of trenching, distributing and placing pipe, calking and backfilling. Sometimes the cost of lead and yarn is included as "cost of laying." Every carefully kept record of cost should contain the following items of cost, expressed in terms of the lin. ft. of pipe of stated size and weight:

Materials:

- Cast iron pipe.
- Lead for joints.
- Yarn.
- Wood blocks, if any.

Labor:

- Labor loading wagons from cars.
- Teams hauling.
- Labor unloading.
- Labor distributing along the trench.
- Teams trenching.
- Labor excavating trench.
- Labor digging bell holes.
- Labor backfilling holes.
- Teams backfilling holes.
- Labor pumping.
- Labor placing pipe in trench.
- Labor placing yarn in joints.
- Labor melting and pouring lead.
- Labor calking joints.
- Foremen, water boy, watchman.
- General superintendence, timekeeping and office expense.

Supplies and Tools:

- Timber, etc., for bracing.
- Fuel.
- Repairs and depreciation of tools.
- Explosives.

Miscellaneous.

- Pay roll insurance (accident).
- Insurance of public (accident).
- Premium on contractors' bond.

While the lineal foot is the common unit used in expressing the cost of a pipe line, it should be remembered that the principle item of labor cost is trenching, which is better reduced to the cubic yard of excavation as the unit. The cost of loading and hauling the pipe should also be reduced to the ton and the ton-mile, as the best units for comparing costs.

The material and labor cost of "specials," valves, hydrants, meters, service pipes, etc., should be recorded separately, and not lumped in with the cost of the main pipe line.

The length of the job should be recorded, for usually there is a certain amount of time required to organize the gang of men, to weed out incompetents, etc. Then, too, there is generally a "fixed expense" (independent of the length of the job), involved in getting the materials, plant and men onto the job, ready for work. The effect of these items is well shown in some cost records given on page 663.

The cost of removing an existing pavement and relaying the pavement should be recorded as a separate item, expressing it in terms of the square yard of pavement. See the section on Roads, Pavements and Walks.

Cost of Loading and Hauling Cast Iron Pipe.—Three men assisted by a driver averaged 5 lengths of 12-in. pipe loaded from a flat car onto a wagon in 12 mins. Planks were laid from the car to the wagon and the pipe was rolled down the plank runway. This same gang would unload a wagon in 6 mins. As each length of pipe weighed nearly $\frac{1}{2}$ short ton, the wagon load was $2\frac{1}{2}$ tons. It, therefore, cost 5 cts. per ton to load and $2\frac{1}{2}$ cts. per ton to unload the wagons, wages of men being 15 cts. per hr.; but this does not include the lost time of the two horses during loading and unloading, which is equivalent to about 3 cts. per ton. The total fixed cost of loading and unloading was 10 cts. per ton, including team time, to which must be added the hauling costs of 13 cts. per ton per mile, where $2\frac{1}{2}$ tons are the load (wages of team and driver 25 cts. per hr.), and the team returns empty. Good, hard, level roads are required for so large a load. If the haul is short and this loading gang of 3 men walks along with the wagon, the cost of hauling becomes 25 cts. per ton mile, instead of 10 cts.

Pipe should never be shipped in hopper-bottom cars, for the difficulty of unloading adds very much to the cost. I have had a gang of 6 men who unloaded only 75 lengths of 12-in. pipe in 10 hrs. from a hopper gondola, into wagons. Each length weighed 800 lbs., making 30 tons the day's work, at 30 cts. per ton. This work was by hand, no derrick being available.

Water Pipe Trenches.—Trenches for water pipes in the northern part of America are usually 5 ft. deep from the surface of the street to the axis of the pipe. In the South, trenches are only 3 ft. deep. Water-pipe trenches are usually dug not less than 18 to 24 ins. wider than the inside diameter of the pipe; and just before the pipes are laid a gang of men enlarges and deepens the trench for a short space where each pipe joint is to come; this is called digging the "bell-holes." The bell-holes enable the yarners

and calkers to make the joints properly. It is usually not necessary to brace the sides of a trench that is only 5 or 6 ft. deep, to prevent caving in. The shallow depth and the absence of bracing make waterpipe trenching cheaper than sewer trenching.

The backfilling is often done entirely by hand, the earth being rammed in thin layers. This is far more expensive than backfilling with a drag scraper pulled by horses, as is shown in the examples that follow.

The reader is referred to the Sewer Section for additional data on trench work.

There are several excellent makes of trench excavating machines on the market. Where enough work exists to warrant the purchase of one of these machines, and where neither boulders nor numerous buried pipe lines occur, trenching with these machines is far cheaper than hand work.

The cost of excavating a water pipe trench with one make of trench machine is given in the next paragraph. Costs of similar work in sewer trenching and in tile ditching will be found in the Sewer Section and in the Miscellaneous Section. See also the sections on Earth Excavation and Rock Excavation. All data relating to trenching will be found by consulting the index under Trenching.

Cost of Digging a 36-Mile Trench With a Buckeye Traction Ditcher.*—A wooden pipe line is used to bring the water from the mountains for the new water system of the city of Greeley, Colo. This line is 36 miles long. Of this distance 2,000 ft. was in rock. This part was excavated by hand and the rest of the trench was excavated by a Buckeye traction ditcher, manufactured by the Buckeye Traction Ditcher Co. of Findlay, O.

For eight miles the trench ran through a stratum of gravel, containing many stones; some of the gravel was also cemented together. The material in the rest of the trench was clay, rather hard, but the machine dug it with great ease. In a ten hour day the machine in the gravel would dig from 600 to 1,000 ft., while in the clay as much as 2,500 ft. of trench was dug in 10 hours. The style of machine used is shown in the accompanying cut. It was a 28-in. by 7½-ft. drainage machine. Such a machine is designed for digging ditches for draining land, the type meant for contractors' use in heavy trench work being more substantially constructed and of greater weight. This machine weighed 17 tons, while a contractor's machine of the same size would weigh 24 tons and cost \$1,300 more than this machine did when new.

The Buckeye ditcher, Fig. 2, being a traction engine as well as a ditch digger, moves along automatically as it digs the trench. It throws the excavated material into the conveyor belt alongside of the wheel, and this belt dumps the earth clear of the ditch, so that the earth does not interfere with the pipe laying and other work that may have to be done in the trench. The bottom of the trench is rounded by the buckets on the wheel, so that pipe laid in the

**Engineering-Contracting*, Feb. 12, 1908.

Fig. 2.—Trench Digger.

trench does not roll from side to side. Two men can operate the machine under favorable circumstances. In backfilling the material can be pushed into the trench by the ditcher, used as a traction engine, by fastening a plank to an outrigger, which acts in a manner similar to a snow plow. A drag scraper can also be used in backfilling. The fact that the machine pulverizes the earth to a great extent in digging makes the backfilling easier than when the earth is in chunks.

The trench dug at Greeley was throughout its entire length 30 in. wide and 4 ft. deep. This meant that a lineal foot of trench contained 10 cu. ft. of earth or .37 cu. yd. As the total length of trench dug by the machine was 188,080 lin. ft., in all 69,659 cu. yds. of earth were excavated. All the work of excavating with the machine was done by 4 men. The man running the ditcher was paid \$5 per day, and the other three \$3 per day of 10 hours. The men worked 300 days. The ditcher when new cost \$5,200, but this machine had been used before, and was bought by the contractors as a second hand machine.

In the summary of cost given below we have allowed \$6 per day for repairs and renewals and interest and depreciation, which is 30 per cent per annum on the original cost of the machine. We are informed by the contractors that this machine used on an average of 1 ton of coal per day, the coal costing \$5 per ton.

The cost of digging the trench was:

300 days, engineer	\$1,500.00
900 days, helpers	2,700.00
300 tons coal	1,500.00
300 days, plant charges at \$4.....	1,200.00
Total	\$7,500.00

This cost, as will be seen, does not include any general expenses, the cost of getting the machine to and from the job or the cost of backfilling.

The cost of water used for one of these machines is nominal, as they use about 1 gallon of water for each pound of coal.

The cost per lineal foot of trench for each item was:

Engineer	\$0.008
Helpers	0.014
Coal	0.008
Plant	0.010
Total	\$0.040

The average number of lineal feet dug per day was 627, although, as previously stated, much more than this was done when the ditcher was actually working. The average given includes all lost time. This machine is speeded to dig 3 lin. ft. of trench 3 ft. deep per minute, and 2 lin. ft. of 4½-ft. trench per minute. In good material better speed than this was obtained, but naturally it could not be made continuously. The same thing may be said in regard to the yardage excavated. On some days more than 900 cu. yds. of material were excavated, but the average yardage per day for the entire job was 231.

The cost per cubic yard for the work was as follows:

Engineer	\$0.021
Helpers	0.040
Coal	0.021
Plant	0.025
Total	\$0.107

This is low cost for trench excavation, even for a ditch only $4\frac{1}{2}$ ft. deep.

The contractors for this work are the Jacobsen-Bade Co. of Portland, Oregon.

Trenching in Quicksand, Using a Helm Trench Machine.^a—The work comprised the placing of a 20-in. main in trench from 5 ft. to $13\frac{1}{2}$ ft. deep connecting two reservoirs at Madison, Wis. The conditions were quite different. The new reservoir was located in a low marshy soil with its bottom 5 ft. below the surface, the bottom of the old reservoir was 16 ft. below the surface. The main connecting the two reservoirs was 1,068 ft. long.

Beginning at a depth of 5 ft. at the new reservoir, the trench curving to the rise in the ground surface increased to a depth of 10 ft., at 425 ft. from the starting point. Here an old lake bed of $4\frac{1}{2}$ ft. of quicksand and a stream of running water was encountered. This quicksand and water had to be contended with to the end of the pipe line and with an increasing depth of trench to $13\frac{1}{2}$ ft. Besides the unstable soil there were several interfering pipe lines.

Work was begun with an ordinary derrick, but this was soon abandoned for a four-leg saw-horse derrick with a traveler. For the more difficult portions of the work still another derrick or trench machine, that shown in Fig. 3, was devised. This machine was used for handling excavation and pipe. It was 36 ft. long, with four buckets and two crank gears to raise and lower them. The same apparatus was used to handle the pipe, a 12-ft. length of which weighed a ton. These men did the excavating and lowered the pipe. The trench had to be sheeted to from 2 to 3 ft. below the bottom with 3-in. plank braced every 3 ft. The rate of progress was one length of pipe laid every $1\frac{1}{2}$ days. Toward the end of the saw-horse derrick work it took three days to lay a length of pipe and by the ordinary methods it is stated that the same work would have required seven days. The machine also reduced the excavating force by 15 men. Mr. John B. Helm, superintendent, under whose direction the work was done, estimates the saving per length of pipe due to the machine \$168.50, or for 23 lengths of pipe laid at \$3,775.50. He writes further regarding the work as follows:

"We had to pump day and night and dare not pump any faster than to keep the water down for fear of drawing the quicksand back of the sheeting into our trench and undermining the dirt.

"The buckets were on a swivel and held by a spring, and were emptied on the pipe as we moved along. It took us over three

^a *Engineering-Contracting*, Sept. 29, 1911.

months to lay 646 ft. of main with from fourteen to eighteen men at times used to trim the street after us. We did not interfere with the street or street railway traffic. It was a macadamized street, and, in spite of the treacherous soil working in at the back of the sheathing, we left the street in a passable condition for the winter. There was only slight settling here and there in the spring. During the whole slogs we had to contend with the water, gas and sewer laterals, and towards the end we had to cut diagonally across the street. Here we had to go under a 6-in., an 8-in. and a 12-in. water main, a 16-in. suction-main from the artesian wells, a gas main, two sewer mains and the street railway tracks, at a depth

Fig. 3.—Trench Machine.

of $12\frac{1}{2}$ ft., with $6\frac{1}{2}$ ft. of quicksand and a continuous stream of water to fight. Our trenching machinery did away with building platforms to bring the soil to the top, saving us at least fifteen men to do this labor, besides requiring only three men to lower the pipe, so easy to handle, blocked to grade, as our fall is only 1 ft. in a distance of 1,068 ft., towards the old storage reservoir by gravity. With the saw-horse derrick, towards the end, when our depth increased, it required three days to lay a pipe, so that we gained, besides the fifteen men, one and a half days for each length, not figuring at an increased depth to lay the same. Where we encountered so many pipes going across the street and at times the different laterals, we had to lower the pipe at a slant and at times perpendicular. The work was accomplished with ease. I do not

see how we could have got along without this machine, and without the machine we could not have accomplished the work before the cold weather set in, besides working at a greater expense."

The trench machine illustrated was designed by Mr. John B. Heim, superintendent Department of Water Works, Madison, Wis., who gives the cost of the main as follows.

Pipe, specials, valves, lead, hemp, coke, etc., with freight and cartage	\$ 6,300
Lumber, machinery, braces, blocks, pumps, etc.....	1,676
Labor	4,870
Total	\$12,846

This gives a cost per foot of $\$12,846 \div 1,060 = \11.647 .

Cost of Trenching at Corning, N. Y.—A trench for a 10-in. water pipe was excavated $2\frac{1}{2}$ ft. wide \times 5 ft. deep \times 1,500 ft. long = 800 cu. yds. in $4\frac{1}{2}$ days by 24 men, or at the rate of 6 cu. yds. per man per 10-hr. day, equivalent to 11 cts. a running foot or 25 cts. a cu. yd. The backfilling was done in 3 days by 2 men and 1 horse with driver, using a drag scraper and a short length of rope so that the horse worked on one side of the trench while the two men handled the scraper on the opposite side, pulling the scraper directly across the pile of earth. In this way the backfilling was made at a cost of 1.1 cts. per lin. ft. or $2\frac{1}{2}$ cts. per cu. yd., there being no ramming of the backfill required. This is a remarkably low cost for backfilling, and one not ordinarily to be counted upon. The material was a loamy sand and gravel.

At Rochester, N. Y., with the size of trench and kind of material practically the same as above:

1 man excavated 8 cu. yds. a day at cost of 19 cts. per cu. yd.

1 man backfilled 16 cu. yds. a day at cost of 9 cts. per cu. yd.

Total cost of excavation and backfill, 28 cts. per cu. yd.

The cost of laying the 10-in. pipe was as follows, 800 ft. being laid per 10-hr. day by the gang:

3 laborers digging bell holes at \$1.50.....	\$4.50
3 laborers laying pipe at \$1.50.....	4.50
1 man hempling joints at \$2.50.....	2.50
2 men pouring lead at \$2.50.....	5.00
3 men calking joints at \$2.50.....	7.50

Total, 800 ft. at 3 cts. **\$24.00**

This does not include trenching nor hauling and distributing pipe.

Cost of Trenching, Great Falls, Mont.—The Great Falls (Montana) Water Co. excavated 25,500 cu. yds. of earth, 1,900 cu. yds. of loose rock, and 1,500 cu. yds. of solid rock, in trenching for a 6-in. water pipe. The work was done by company labor (not by contract), wages being \$12.25 for laborers, and the cost was 34 cts. per cu. yd. for excavation and $3\frac{1}{2}$ cts. more per cu. yd. for backfilling and tamping. If wages had been \$1.50 a day the cost would have been 23 cts. per cu. yd. for excavation and $2\frac{1}{2}$ cts. per cu. yd. for backfilling.

Cost of Trenching, Astoria, Ore.—Mr. A. L. Adams states that in trenching for the Astoria (Oregon) Waterworks, in 1896, the

first contractor averaged only 7 to 8 cu. yds. per man per day. Later on another contractor, even in the rainy season, averaged nearly 10 cu. yds. per man per 10-hr. day of trenching (including backfilling), at a cost (including foreman) of $17\frac{1}{2}$ cts. per cu. yd., wages being \$1.70 a day. The material was yellow clay dug with mattocks and shovels.

Cost of Trenching, Hillburn, N. Y.—Mr. W. C. Foster gives the following data on 17,000 ft. of trenching for water pipe at Hillburn, N. Y. The trench was 4 ft. deep, for 4-in. to 8-in. pipe. The digging was hard, the banks being full of cobbles and frequently caved in. The streets were not paved. The cost of trenching and backfilling was 10.1 cts. per lin. ft., wages being \$1.35 for laborers and \$3 for foremen.

Cost of Pipe Laying, Providence, R. I.—Mr. E. B. Weston, Engineer Water Department, Providence, R. I., gives the following tables based upon many miles of trench work done prior to 1890:

EASY DIGGING, SAND.

*Including backfilling, and in all cases the depth of the trench was such that the center of the pipe was 4 ft. 2 ins. below ground surface.

Wages in all cases above were \$1.50 a day for laborers trenching and laying, \$3 a day for foreman, \$2.25 for calkers, and \$2.25 for teams which probably refers to team without driver. Carting was in all cases \$1 a ton. Allowance for tools, item 4, was made on a basis of 7.2% of items 1 and 2.

—Tap and stop—		—Lead service pipe per lin. ft.—		
Diam. in ins.	Tap, stop, etc. including tapping.	Diam. in ins.	Weight in lbs.	Cost of pipe trenching laying, etc.
3/4	\$6.00	3/4	3.00	\$0.34
1 1/2	6.23	1 1/2	4.00	.40
2	6.81	2	4.75	.45
3	8.67	3	6.00	.52
4	10.71	4	9.00	.70
...	1 1/2	10.00	.76

In the above, lead pipe was assumed at 6 cts. per lb.; labor of trenching and laying, 16 cts. per ft.

Short lengths, 15 to 50 ft., of 8-in. pipe cost 24 cts. per ft. in easy digging to 45 cts. in hard digging for excavation, laying and backfilling, wages being as above stated.

The trench for a 24-in. pipe, 19,416 ft. long and 6.6 ft. deep cost 32 cts. per cu. yd. for excavation and backfill, with wages at \$1.50 a day.

A 48-in. main was laid for \$1.65 per ft. including digging, laying, calking and backfilling.

A 16-in. pipe, 374 ft. long passed under two railway tracks, and the cost of trenching, laying and backfilling was 50 cts. per ft.

An 8-in. pipe was laid across a bridge, and the cost of boxing, laying pipe, etc., was \$1.32 per ft., while for a 12-in. pipe the cost was \$1.50 per ft.

Trenches were ordinarily 2 ft. wider than the pipe and 5 ft. plus half the diameter of the pipe deep. Such trenches were dug, the pipe laid and backfilling made at the following rate per laborer engaged:

8-in. pipe, easy earth.....	21.0	lin. ft. per day
8-in. " medium earth.....	17.2	" "
8-in. " hard earth.....	10.3	" "
8-in. " easy earth.....	19.3	" "
12-in. " medium earth.....	13.4	" "
20-in. " easy earth.....	9.0	" "
24-in. " medium earth.....	4.4	" "

Earth excavation in trenches where digging is easy costs 20 cts. per cu. yd.; rock excavation averages \$2 per cu. yd. and runs as high as \$3, wages being \$1.50 a day for labor.

Cost of Laying 107,877 Feet of Water Mains at Cleveland, O.—During 1907 the Pipe Laying Department of the Division of Water Works of Cleveland, O., laid 107,877 ft. of watermains, the sizes of pipe and lengths laid being as follows:

*Engineering-Contracting, Nov. 4, 1903.

30-in.	5,320 ft.
24-in.	11,164 ft.
20-in.	1,665 ft.
12-in.	17,362 ft.
10-in.	1,181 ft.
8-in.	16,099 ft.
6-in.	53,416 ft.
4-in.	439 ft.
3-in.	2,222 ft.

Table II, prepared by M. E. Bemis, superintendent of water works, shows the unit cost of laying these watermains.

Mr. Bemis states that the costs were rather high, owing to the unusually high prices of materials prevailing during the year. The prices for materials at Cleveland, during 1907 were as follows:

	Per ton.
All sizes of cast iron pipe, delivered on streets, for the first half of 1907.....	\$36.25
For the second half of 1907.....	36.00
Miscellaneous castings and special castings, from 3-in. to 16-in., inclusive, first half of 1907	54.00
Miscellaneous castings over 16-in., first half of 1907	60.00
Miscellaneous castings, second half 1907..	59.90
Special castings, from 3-in. to 16-in., inclusive, second half 1907.....	65.00
Special castings, over 16-in., second half 1907	75.00
	Each.
3-in. valves	\$ 6.53
4-in. valves	7.63
6-in. valves	12.60
8-in. valves	18.90
10-in. valves	26.25
12-in. valves	34.50
16-in. valves	66.15
20-in. valves	134.25
24-in. valves	217.50
3-in. hydrants	20.00
4-in. hydrants	27.75
6-in. hydrants	46.25
Pig lead, first half of 1907	\$123.20 per ton f. o. b. point of shipment
Pig lead, second half of 1907.....	\$101.00 per ton f. o. b. cars at Cleveland
Packing	4½¢ per lb.

The wages paid for labor were as follows:

	Per hour.
Foreman	\$0.42
Assistant foreman	0.33
Calkers	0.27½
Labor	0.22
Team	0.50

Cost of Water Pipes Laid at Boston.—Mr. C. M. Saville gives the following data relative to 62 miles of pipe work done by contract for the city of Boston: The costs are averages of the actual costs under 21 contracts, from 1896 to 1903. As a general rule the

HANDBOOK OF COST DATA.

*On 30-in. mains 24-in. valves were set and on 24-in. mains 20-in. valves were set.

†includes paving and other items of like nature.

pipes were laid with the axis of the pipe 5 ft. below the surface. The pipes were usually placed in the trench by a hand operated derrick spanning the trench. In practically all cases the streets were macadamized. Just how many feet of each kind of pipe were laid is not stated; but there were not less than the following amounts:

12-in. pipe	15,500 ft.
16-in. pipe	44,600 ft.
20-in. pipe	21,200 ft.
24-in. pipe	19,600 ft.
30-in. pipe	7,200 ft.
36-in. pipe	36,800 ft.
48-in. pipe	97,900 ft.

The first item in Table III of \$30 per ton for pipe was calculated by adding 12% to the actual cost of \$26.80 per ton, this 12% being added to cover incidentals. These incidentals are as follows, by percentages:

	Per cent.
Small pipes for blow-offs and connections....	1 1/2
Special castings	4 1/2
Valves	5
Miscellaneous materials	1

Total percentages to be added to the cost
per short ton of straight pipe.....12

The cost of teaming on 21 contracts previous to 1898 was 26 cts. per ton per mile, the average haul being 2.4 miles from the pipe yards; but, in order to be liberal, 30 cts. per ton per mile for a 2 1/2-mile haul is assumed as an average; wages of two-horse team and driver being 45 cts. per hr.

The lead is estimated at 5 cts. per lb., and each joint requires about as many pounds of lead as 2 times the diameter of the pipe in inches, according to Mr. Saville, but other authorities do not agree with him.

The column headed "miscellaneous expenses" is based upon actual experience, and includes cost of tools, insurance of men, lumber, yarn, and incidental expenses. The tools depreciate about 50% on any contract. It was estimated that 4% of the cost of laying the pipe should be added to cover the cost of tools. The cost of accident insurance was 2% of the pay roll. The contractor's bond cost 1/2% of the bond. Incidental expenses were about 1% of the pay roll. It was estimated that these three items amounted to 3.2% of the cost of laying the pipe. The cost of lumber, yarn, etc., averaged 2.8% of the cost of hauling and laying. Hence, the total cost of "miscellaneous expenses" was 4% + 3.2% + 2.8%, which is 10% of the cost of laying the pipe. The word "laying" is here used to include the cost of hauling the pipe, the cost of lead, the cost of trenching and backfilling, and the cost of placing the pipe in the trench and calking it.

The column headed "labor" includes the cost of trenching in earth (there was very little rock), and the cost of placing the

pipe in the trench and calking it. Wages paid for labor were as follows:

Foreman	\$100.00	per month
Sub-foreman	3.00	per day
Calkers and yarners.....	2.50	"
Laborers, 1st class.....	1.75	"
Laborers, 2d class.....	1.60	"
Double team and driver.....	0.45	per hour
Single team and driver.....	0.30	"

A considerable amount of extra work was done by force account on 28 miles of the pipe line, averaging 12 cts. per ft. of line, due to obstructions encountered causing changes of location, etc.

Cost of Laying Main Water Pipe in Boston, Mass., 1878-1907.*—
The gradual increasing average labor cost of laying water pipe

Cost per foot in cents

Eng. Contr.

LENGTH IN FEET

Fig. 4.—Effect of Length of Job on Cost.

in Boston is made the subject of one of the reports prepared by Metcalf & Eddy, consulting civil engineers to the Boston Finance Commission. Nearly all the pipe laid was 8-in. pipe; but some 6-in. and 10-in. pipe is included and a little 12-in. pipe. Since, however, this range in sizes involves substantially no change in trench dimensions the cost per foot should be directly comparable. The average labor costs per lineal foot of laying water pipe, taken from the city engineer's records for the years 1878 to 1907, inclusive, are given in Table IV. These are the figures on which the engineers' computations which follow are based.

It will be seen from the table that, during the period covered, wages advanced, the hours of labor decreased and the labor performed per hour also advanced.

Figure 4 shows the general relation of the cost per foot to the

**Engineering-Contracting*, Aug. 18, 1909.

TABLE IV.—LABOR COST PER LINEAR FOOT OF LAYING WATER PIPE IN BOSTON.

Year.	Wages per day.	Number of jobs.	Total length of pipe (feet).	Average length of job (feet).	Hours per week.	Max.	Min.	Average actual cost.	Average cost reduced to uniform basis of 60 hrs. per week.	Average cost reduced to uniform basis of 600 ft. job.

Labor cost per foot in cents.

length of the job for five of the years under consideration, viz.: 1886, 1891, 1896, 1902 and 1906. It will be seen that the form of curve is substantially similar in all cases. From these curves was computed the increase in labor cost per foot for shorter jobs as compared with the cost for 1,000 ft., in percentages, and the results shown by the dotted curve on the same diagram. This curve shows that the increased cost per foot of a piece of work 100 ft. long, over what it would have been if 1,000 ft. long, is 90 per cent. The increased cost for a 200-ft. job is 55 per cent; for 300 ft., 34 per cent; for 400 ft., 21½ per cent; for 500 ft., 12 per cent, and for 600 ft., 8 per cent.

From the same line of reasoning it is readily apparent that in years when the average length of job is high, the corresponding cost per foot should be less than when the average length is low. From their study of the relations of average length to average total cost per foot, partly by mathematical work and partly by the exercise of judgment, the engineers deduced factors by which the costs can be reduced to an average annual length of job of 300 ft.; the labor cost so reduced is given in the last column of the table. In other words, this column is intended to show costs which should be absolutely comparable in all particulars, having been reduced not only to a uniform basis of wages and hours of labor, but also to a uniform basis of average length of job.

The results are indicated somewhat more clearly by Fig. 5, showing by the light line the average labor cost as computed by the city engineer for uniform conditions of wages and hours of labor, and by the heavy line the further reduction for a uniform length of job. This latter line shows, under the assumed basis, the average labor cost of about 23 cts. per foot to and including 1893, and a rapidly increasing cost up to 1906. On this diagram the dotted lines show the effect of omitting the work done by contract in 1904, 1905, 1906 and 1907, which had been included by the city engineer. On this basis it is seen that the cost in 1906 and 1907 was somewhat less than in 1905, although greater than in any preceding year.

Further comment upon these diagrams is perhaps superfluous. Metcalf & Eddy emphasize the statement that the increased labor cost can be charged to nothing but inefficiency of labor.

This inefficiency is due to various causes. The engineers elsewhere reported in some detail showing the effect of age upon efficiency. Other causes which doubtless have greater or less effect are lack of discipline, political appointments, and more or less inefficient organization.

Comparative Cost of Pipe Laying in New England Cities.*—As a part of the report by the special Boston Finance Commission, which recently completed its labors, there has been published a volume of some 1,300 pages comprising solely the reports (nearly 60 in number) of Metcalf & Eddy of Boston, consulting civil engi-

**Engineering-Contracting*, July 23, 1909.

In their investigation of the Boston Water Department the engineers made a careful study and analysis of the cost of pipe laying and for the purpose of comparison also investigated the cost of laying pipe by day labor in neighboring cities of Massachusetts. The basis of actual cost differs, in some cases considerably, since the trenches are not of the same dimensions and since wages and

Fig. 5.—Increasing Cost of Pipe Laying in Boston.

hours of labor vary more or less. The engineers attempted, however, to reduce the cost to a uniform basis, so far as possible. Since the data for adjoining cities are based on present costs, or at least costs within a period of a year or two previous to the date of the report, they took the average labor cost of pipe laying in Boston for the 2½ years from 1905 to July 1, 1907, inclusive, for comparison.

In Table V are given, following the name of each city, the wages and hours of common labor during the period under discussion; the length of pipe included in making up the average cost; the years in which this pipe was laid; the actual labor cost per foot; the depth of trench; the corresponding cost per foot for a trench 6 ft. deep, such as is used in the city of Boston; and, finally, the corresponding cost for a 6-ft. trench, if the wages had been uniformly \$2 per day and the hours 60 per week.

In making the computations, it was assumed that a trench 6 ft. deep would cost 20 per cent more per foot than one 5 ft. deep. As a matter of fact the actual increase in cost would probably be something less than 20 per cent, since there would be very little if any increased cost of placing the pipe, making joints, etc., and no increase in the cost of teaming. On the other hand, the cost of excavation for the lowest foot might be a little greater than one-fifth of the average cost, but in most cases probably not enough greater to offset the practically unchanged cost of the items mentioned above. The addition of 20 per cent is, therefore, probably more than ample to allow for the increased depth of trench.

In reducing the actual costs to what they would have been had the wages been \$2 per day and the hours 60 per week, it has been assumed that the actual efficiency of labor per hour was unaffected by the change in hours and wages.

The figures in the last column of the table should be absolutely comparable. The greater difficulties encountered in Boston on account of many obstructions, etc., do not enter, since all jobs involving such difficulties have been rigidly excluded from the computations and comparisons.

From them it is evident that the pipe laying cost in the city of Boston is 69 per cent greater than that of the average of the other seven cities, and nearly 44 per cent greater than the cost in Worcester, where it is the highest of any of the seven.

In the case of Cambridge, besides data showing the cost in 1905, average labor cost per foot was furnished of laying 4, 6, 8 and 12-in. pipe from 1894 to 1903. The fluctuations in these costs are not remarkable and there was no wide divergence from the average during this period of ten years. After adding 20 per cent to make the figures comparable with those for 6-ft. trench in Boston, the average for the ten years was 40.4 cts. per foot for all sizes, or, separating the figures, \$1.4 cts. for 4-in. pipe, 35.1 cts. for 6-in., 43.4 cts. for 8-in. and 51.6 cts. for 12-in. In 1905, however, as already noted, the average cost on the comparative basis was 60.2 cts. per foot, an increase of 49 per cent over the average for the ten years 1894-1903. No data were furnished which explained this sudden increase.

Reducing 40.4 cts. per foot to the \$2 per day and 60 hours per week basis, the comparative labor cost of pipe laying in Cambridge prior to 1904 was found to be \$1.6 cts. per foot. During this same period, 1894-1903, the labor cost in Boston reduced to the same basis was rapidly increasing and ranged from 27.2 cts. at the be-

TABLE V.—SHOWING COMPARATIVE LABOR COST OF LAYING PIPE IN VARIOUS CITIES.

City	Year.		Length of pipe included in computing average cost.	Feet.	Actual cost of labor per ft. of pipe.	Depth of trench.	Computed cost of labor per ft. of pipe for 6-ft. trench.	Corresponding cost of labor per ft. of pipe with wages \$2 and hours 60 per week—trench 6 ft. deep.
	Actual average wages and hours of common labor.	Year.						
Wages. Hours.	Feet.	Actual cost of labor per ft. of pipe.	Depth of trench.	Computed cost of labor per ft. of pipe for 6-ft. trench.	Corresponding cost of labor per ft. of pipe with wages \$2 and hours 60 per week—trench 6 ft. deep.			
Boston	12,151	96.1	6	96.1	70.6			
Worcester*	5,551	50.9	5	51.1	48.9			
Cambridge	50.35	5	50.3	47.3			
Lowell	5,915	48.1	5	58.9	47.1			
Somerville	2,413	45.2	5	54.2	42.5			
Newton	2,238	52.0	5	63.0	42.4			
New Bedford	15,720	34.7	5	41.6	33.2			
Chelsea	2,474	32.7	5	39.3	30.1			
Average of all except Boston	41.7			

*It should be noted that a portion of the work done in Worcester in 1907 showed extremely high costs and the average cost is therefore high. Had the year 1906 been taken the average cost in last column would have been 54.7c.

ginning of the period to 59.2 cts. at the end, or from 18 per cent to 88 per cent more than the cost in Cambridge.

Metcalf & Eddy show that from the foregoing information it can only be concluded that under labor conditions as they exist in other neighboring cities, a fair average labor cost for pipe laying work, reduced to the uniform basis of \$2 per day and 60 hours per week, would be about 42 cts. per foot, with 50 cts. as a maximum. Of course individual pieces of work would often exceed the average and others would frequently fall considerably below it. As against these fair costs, this work cost the city of Boston, on the same basis of hours and wages, about 70 cts. per foot for the three years prior to July, 1907, or from 10 to 70 per cent in excess of its reasonable cost.

Reduced to the basis of hours and wages, at the time of the report (i. e., 44 hours per week and \$2.25 per day), the fair average labor cost as estimated upon the basis of cost in other cities would be 63.7 cts. per foot, with 76.6 cts. as a reasonable maximum, against which the average cost for the previous 3½ years (on the same basis) was equivalent to \$1.081 per foot, an excess of 44.3 cts. per foot, or 69 per cent, over the fair average cost.

It is difficult to estimate the total excess cost resulting from this inefficiency of labor. The lengths of pipe laid from which the average costs were computed—including only those jobs on which there were no special difficulties which might render them not comparable with other jobs, and including no rock excavation—constitute but a small part of the total pipe of these sizes (6 to 12 ins.) actually laid. It is probable that on the jobs involving special difficulties, where the actual labor costs must have been greater, the excess over a reasonable cost was also larger; and on contract jobs, which have usually been done at a less cost than the day labor jobs, the excess over a reasonable cost would be less. The total length of 6-in. to 12-in. pipe laid in the year 1906-7, as stated in the last annual report of the Boston Water Department, was 57,949 ft. If the excess labor cost on all of this may properly be taken as 44.3 cts. per foot on the \$2.25 per day basis, equivalent to 39.2 cts. on the \$2 per day basis, then the city actually paid \$22,900 more than it should have done for labor alone, in laying pipe of 6-in. to 12-in. diameter in 1907.

The total length of main pipes laid in the year 1906-7 was 71,307 ft. Since the inefficiency of labor is not confined to work upon small sizes of pipe, and is experienced in some degree upon the contract work as well as upon that done by day labor, the engineers estimate that this inefficiency resulted in a total excess of cost of pipe laying, for labor alone, amounting to something like \$20,000, and possibly much more, for the year ending January 31, 1907.

Cost of Water Pipe Laying and Placing Hydrants at Atlantic City.—Mr. Kenneth Allen gives the following data relative to the laying of pipe at Atlantic City, N. J., in 1905. The work was done by the Water Department. A 4-in. pipe line, 5,000 ft. long,

was laid in a trench 40 ins. deep, in sand requiring no shoring or pumping.

The average force employed was as follows:

	Per 8 hr. Day.
Trenching and back filling:	
10 men at \$1.50.....	\$15.00
1/2 foreman at \$2.00	1.00
Total, 292 lin. ft. at 5.5 cts.....	\$16.00
Pipe Laying:	
4 pipe handlers at \$1.75.....	\$ 7.00
2 calkers at \$2.50	5.00
1 lead man at \$2.00	2.00
1/2 foreman at \$2.00.....	1.00
Total, 292 lin. ft. at 5.1 cts.....	\$15.00

The total cost per lineal foot of 4-in. pipe was:

	Cts. per ft.
19.66 lbs. cast iron pipe at 1.11 cts.....	21.69
Specials, at 2 1/2 cts. per lb.....	1.69
Valves and boxes	6.26
0.45 lbs. lead at 4.9 cts. per ton.....	2.22
0.024 lbs. Jute, 5 1/2 cts. per ton.....	0.13
0.28 lbs. coke	0.08
Hauling at 75 cts. per ton.....	0.80
Trenching, as above detailed	5.50
Pipe laying, as above detailed.....	5 10
Watchman	0.60
Superintendence	1.25
Total	45.22

The average cost of setting 10 hydrants (4 in.) was as follows per hydrant:

Material	\$2.36
3 days (24 hrs.) at \$1.50.....	4.50
Total	\$7.76

The following was the cost of 4,300 ft. of 8-in. pipe:

	Per ft.
46.6 lbs. pipe at \$22 ton.....	\$0.611
1.04 lbs. lead at 4.9 cts.....	0.054
Jute at 5 1/2 cts.	0.023
Specials, valves, hauling, etc.....	0.217
Labor	0.290
Total	\$1.095

The following was the cost of 3,200 ft. of 10-in. pipe:

	Per ft.
68.7 lbs. pipe	\$0.762
2.04 lbs. lead	0.098
Jute	0.046
Specials, valves, hauling, etc.....	0.124
Labor	0.580
Total	\$1.590

The following was the cost of 3,600 ft. of 12-in. pipe:

	Per ft.
\$4.2 lbs. pipe	\$0.926
2.77 lbs. lead	0.123
Jute	0.042
Specials, valves, hauling, etc.....	0.273
Labor	0.790
Total	\$2.156

It will be noted that the labor cost for the 8, 10 and 12-in. pipe was abnormally high, said to be due to expensive crossings of other pipe lines and to the presence of adjacent gas pipes, etc., which had to be cared for.

Cost of Laying a 14-in. Pipe Line, Wilkes-Barre, Pa.*—The work consisted of laying 750 ft. of 14 in. bell and spigot pipe at Wilkes-Barre, Pa., in October, 1905. The work was done by company labor and the digging was easy. The pipe was distributed with a truck on a narrow gage track along the trench. The pipes were placed in the trench by a hand-operated derrick spanning the trench. The cost of the pipe line was as follows:

Materials:	Total	Per ft
62 pieces 14-inch pipe, 77,773 lbs.....	\$ 937.16	\$1.26
6 pieces 14-inch bends, 2,852 lbs.....	74.87	10
Freight on pipe and bends.....	60.39	.067
1,421 lbs. lead at \$0.05.....	72.05	.050
68 lbs. hemp at \$0.09.....	6.12	.008
Total cost of material.....	\$1,140.59	\$1.521
Labor:	Total	Per ft.
Excavating and distributing pipe, 64 days at \$1.74	\$ 111.36	\$0.148
Laying and calking, 21 3/9 days at \$1.74.....	37.12	.050
Covering over, 12 2/9 days at \$1.74.....	23.01
Covering over, 2 days at \$1.79	3.58	.036
Superintendence and engineering	12.20	.016
	\$ 187.27	\$0.249
Total cost of material and labor.....	\$1,327.86	\$1.770

For the above information we are indebted to Mr. Douglas Bunting, Chief Engineer, Lehigh & Wilkes-Barre Coal Co.

Cost of Water Pipe Laid at Alliance, O.—Mr. L. L. Tribus gives the following costs of work done in 1894, the material being loam and clay excavated to such a depth that 4 ft. of earth would be left on top of each class of pipe after backfilling:

Size of pipe in ins.....	4	6	8	10	12
Wt. of pipe, lbs. per ft...	19	30 1/2	44	62	79
Lbs. special per ft.....	0.4	0.76	1.1	1.55	1.9
Lbs. lead per ft.....	0.4	0.66	1.0	1.35	1.6
Lbs. yarn per ft.....	0.02	0.025	0.05	0.08	0.1
Total length in ft.....	2,890	9,760	1,860	3,320	2,930

*Engineering-Contracting, Nov. 7, 1906.

Cost Per Lin. Foot. Laid.

Size of pipe in ins.....	4	6	8	10	12
Pipe	\$0.2360	\$0.3780	\$0.5350	\$0.7470	\$0.9400
Specials and valves....	.0120	.0189	.0268	.0374	.0470
Hauling0056	.0078	.0110	.0145	.0190
Lead0020	.0030	.0050	.0080	.0150
Yarn0014	.0018	.0035	.0056	.0070
Trenching1240	.1210	.1287	.1480	.1903
Pipe laying0370	.0346	.0313	.0542	.0462
Total	\$0.4360	\$0.5951	\$0.7863	\$1.0697	\$1.3245

This work was done by laborers and men employed by the water company and does not include cost of superintendence. The 4-ft. cover over the pipe was in some cases exceeded. The digging was comparatively easy with little ground water to bother. Mr Tribus informs me that the wages paid were: Laborers, \$1.25; pipe handlers, \$1.50; and calkers, \$2.25, per 10-hour day.

Cost of Water Pipe and Service Connections at Porterville, Cal.—Mr. P. E. Harroun gives the following data on laying 4, 6, 8 and 10-in. water pipe and making service connections, at Porterville, Cal., in 1904. The work was done by company labor, and the workmen were very inefficient. All trenches were 1½ ft. wide and 3½ ft. deep in a heavy adobe (clay), except for short stretches in sand as hereafter noted. The streets were not paved, but covered with 4 ins. of hard rolled clay and gravel which required a 4-horse plow to break through. In backfilling, a "go devil" was used to throw the material into the trench wherever practicable, and water from street hydrants was used to consolidate the back fill.

Cost of 4-in. water pipe line (2,846 ft. long, of which 900 ft. were in sand):

	Per ft.
Labor trenching, at 20 cts. per hr.....	\$0.070
Two horses trenching, at 15 cts. per hr.....	0.001
Labor digging bell-holes, at 20 cts. per hr.....	0.016
Labor laying pipe, at 20 cts. per hr.....	0.010
Yarners, at 22½ cts. per hr.....	0.005
Labor pouring lead, at 20 cts. per hr.....	0.004
Calkers, at 25 cts. per hr.....	0.003
Labor backfilling, at 20 cts. per hr.....	0.011
Two horses backfilling, at 15 cts. per hr.....	0.004
Distribution of materials, at 60 cts. per ton.....	0.005
Miscellaneous labor	0.004
Foreman, at 40 cts. per hr.....	0.017
Timekeeper	0.002

Total cost of laying per ft.....\$0.156

The cost of materials for this 4-in. pipe line was as follows:

	Per ft.
Pipe (2,820 ft., 30 short tons), \$44.40.....	\$0.461
Specials (4,462 lbs.), at 3½ cts.....	0.051
Valves (9), at \$9.40.....	0.030
Hydrants (5), at \$28.60.....	0.050
Lead (2,010 lbs.), at 5.3 cts.....	0.028
Yarn (105 lbs.), at 5.4 cts.....	0.002
Tools	0.015
Miscellaneous	0.006

Total materials per ft.\$0.652

WATER-WORKS.

673

Cost of 6-in. water pipe line (838 ft. long, of which 300 ft. were in sand):

	Per ft.
Labor trenching, at 20 cts. per hr.....	\$0.073
Two horses trenching, at 15 cts. per hr.....	0.001
Labor digging bell-holes, at 20 cts. per hr.....	0.017
Labor laying pipe, at 20 cts. per hr.....	0.013
Yarners, at 22½ cts. per hr.....	0.005
Labor pouring, at 20 cts. per hr.....	0.007
Calkers, at 25 cts. per hr.....	0.010
Labor backfilling, at 20 cts. per hr.....	0.012
Two horses backfilling, at 15 cts. per hr.....	0.004
Miscellaneous	0.005
Distribution of materials, at 60 cts. ton.....	0.012
Foreman, at 40 cts. per hr.....	0.013
Timekeeper	0.002
Total cost of laying per ft.....	\$0.181

The cost of materials for this 6-in. pipe line was as follows:

	Per ft.
Pipe (816 ft., 12.12 tons), at \$43.40 per ton.....	\$0.679
Specials (1,420 lbs.), at 2½ cts.....	0.055
Valves (10), at \$15.65.....	0.187
Hydrants (9), at \$29.85.....	0.220
Lead (804 lbs.), at 5.3 cts.....	0.052
Yarn (42 lbs.), at 5.4 cts.....	0.003
Tools	0.016
General	0.010
Total materials per ft.	\$1.322

Cost of 8-in. water pipe line (2,558 ft. long, of which 300 ft. were in sand):

	Per ft.
Labor trenching, at 20 cts. per hr.....	\$0.071
Labor digging bell-holes, at 20 cts. per hr.....	0.016
Labor laying pipe, at 20 cts. per hr.....	0.016
Yarners, at 22½ cts. per hr.....	0.008
Labor pouring, at 20 cts. per hr.....	0.006
Calkers, at 25 cts. per hr.....	0.012
Labor backfilling, at 20 cts. per hr.....	0.012
Two horses backfilling, at 15 cts. per hr.....	0.004
Miscellaneous	0.004
Distributing materials, at 60 cts. per hr.....	0.013
Foreman, at 40 cts. per hr.....	0.017
Timekeeper	0.002
Total cost of laying per ft.....	\$0.183

The cost of materials for this 8-in. pipe line was as follows:

	Per ft.
Pipe (2,512 ft., 57.61 tons), at \$43.40.....	\$0.978
Specials (4,056 lbs.), at 2½ cts.....	0.052
Valves (5), at \$24.....	0.047
Lead (2,618 lbs.), at 5.3 cts.....	0.076
Yarn (189 lbs.), at 5.4 cts.....	0.004
Tools	0.015
Miscellaneous	0.009
Total materials per ft.	\$1.181

Cost of 10-in. water pipe line (124 ft. of pipe, 14 ft. of specials; total, 138 ft.):

	Per ft.
Labor trenching, at 20 cts. per hr.....	\$0.174
Labor digging bell-holes, at 20 cts. per hr.....	0.016
Labor laying pipe, at 20 cts. per hr.....	0.023
Labor yarning, at 20 cts. per hr.....	0.002
Labor pouring, at 20 cts. per hr.....	0.002
Labor calking, at 20 cts. per hr.....	0.016
Labor backfilling, at 20 cts. per hr.....	0.060
Labor miscellaneous, at 20 cts. per hr.....	0.015
Distribution of materials, at 60 cts. to 1.....	0.020
Foreman, at 40 cts. per hr.....	0.016
Timekeeper	0.002
Total labor per ft.....	\$0.343

The cost of materials for this 10-in. pipe line was as follows:

	Per ft.
Pipe (124 ft. 3.74 tons), at \$43.40.....	\$1.179
Specials (603 lbs.), at 3½ cts.....	0.178
Valves (1), at \$34.60.....	0.251
Lead (268 lbs.), at 5.3 cts.....	0.105
Yarn (14 lbs.), at 5.4 cts.....	0.005
Tools	0.015
Miscellaneous	0.009
Total materials per ft.....	\$1.742

Cost of service connections (¾-in. screw pipe):

	Each.
Labor trenching, at 20 cts. per hr.....	\$0.612
Tapping and making, at 40 cts. per hr.. . . .	1.003
Tapping and helper, at 20 cts. per hr.....	0.289
Backfilling, at 20 cts. per hr.....	0.206
Total labor per connection.....	\$2.111

The cost of materials for each service connection was as follows:

	Each.
Goosenecks and cocks	\$2.48
Fittings	0.40
Tools (\$68)	0.88
Tapping machine (\$81).....	1.03
Total materials and tools per connection.....	\$4.79

It will be noted that the full cost of the tools and tapping machine is charged to these 78 connections, making the cost of each unusually high.

Assuming, as above stated, that the trenches averaged 1½ ft. wide and 3¼ ft. deep, the cost per cubic yard of trench work was as follows:

	Cents.
Digging trench	38
Digging bell-holes	8¼
Backfilling	8¼
Total per cu. yd.	55

An Unusually Expensive Piece of Work.—"G. S. W. '88" in The Technic of 1896, gives the following, the material in all cases being clay: Wages of laborers 15 cts., pipe handlers 16 to 17½ cts., foreman 20 cts. per hour; depth of trench, 4 to 5½ ft.:

Example	A	B	C	D
Size of pipe, in.	24	24	12-16	10
Length of pipe, ft.	2,550	2,200	6,241	8,969
Excavation, cu. yds.	2,710	1,963	3,441	4,508
Surplus earth,* cu. yds.	1,300	862	1,033
Cost of excavation per ft.	\$0.2725	\$0.333	\$0.2061	\$0.2416
Cost of pipe laying, per ft.	.2480	.182	.2089	.0939
Cost of bell holes, per ft.	.1500	.128	.0954	.0098
Cost of backfilling, per ft.	.1790	.191	.1228	.1360
Cost of ramming, per ft.	.7927†	.107‡	.2896†	.1322†
Cost of tile, hose work, per ft.0740200
Cost of loading excess earth, ft.	.0895	.046	.0358	.0025
Cost of carting excess earth, ft.	.0636	.055	.0636	.0046
Total labor cost per ft.	\$1.7953	\$1.116‡	\$1.0318	\$0.6433
Cost of excavation, cu. yd.	0.2562	0.373	.3736	.4807
Cost of backfilling, cu. yd.	0.1684	0.216	.2226	.2706
Cost of ramming cu. yd.	0.7461†	0.121	.5434†	.8618†
Cost of tile, hose work, cu. yd.	0.084
Swelling of material on loosening	44%	\$0. to 44 1/2%*	20%

*This surplus earth was hauled away in wagons, after filling the trenches and leaving a 4-in. crown to provide for settlement.

‡1,400 feet of this trench was backfilled without ramming, using water instead; ramming, however, was much more effective in compacting the clay.

†Rammed dry in 4-in. layers.

‡Rammed wet; the portion that was rammed dry cost \$1.40 per ft. total.

||This total does not check with the items, so there must be an error somewhere.

With labor at \$1.25 for 8 hours and material clay as before, streets paved with wood. "G. S. W." also gives the following:

Example	E.	F.	G.	H.
Size of pipe in in.	12	12	10	8
Depth of trench, ft.	6	5	5	5
Length of trench, ft.	1,048	2,475	2,592	2,049
Cost of excavation, per ft.	\$0.186	\$0.134	\$0.1920	\$0.1442
" pipe laying, per ft.	.257	.162	.1218	.0678
" backfilling, per ft.	.450	.390	.3949	.3632
" hauling surplus, per ft.	.014	.011	.0101	.0194
Total labor cost per ft.	\$0.907	\$0.697	\$0.7188	\$0.5746

The two most striking features in the foregoing data are (1) the enormous swelling of the clay upon loosening and casting it out of the trenches, and (2) the extraordinary high cost of ramming the clay in backfilling. It is difficult to explain either of these items except upon the assumption that the loosened clay dried out when exposed to the sun and air, forming hard rock-like clods which no amount of ramming seems to have consolidated effectually. Adding water as in Example B seems to have had no very good effect in consolidating the backfill, although it was less expensive than ramming. But it is a well-known fact that water makes dry clay swell, and it does not cause layers of hard lumpy clay to

settle in a trench except as a result of weeks of slow seepage of rains.

It will be noted that all this work was extraordinarily expensive. Even the pipe laying cost double the usual amount. We may infer that this work was not done by contract but by day labor for a municipality or a company, and that the foreman did not secure "a day's work" from the men—which is so often the case in municipal day-labor work.

Cost of a 6-in. Pipe Line in Ohio.—Mr. E. H. Cowan has given me the following data: A 6-in. pipe line, $1\frac{1}{2}$ miles long, was laid in an Ohio city by contract, the cost per foot of pipe line to the contractor being as follows:

	Per ft.
33.74 lbs. of 6-in. pipe, at \$24 per short ton.....	\$0.405
0.67 lb. of specials, at 2% cts. per lb.....	0.018
Hydrant connections, 4-in.....	0.008
Hydrants, \$28 each.....	0.045
Gates (\$12.50 each) and gate boxes (\$3.09 each).....	0.054
0.74 lb. lead, $4\frac{1}{4}$ cts. per lb.....	0.023
0.07 lb. jute packing, 3% cts. per lb.....	0.003
Labor, $18\frac{1}{2}$ to 26 cts. per ft. averaging.....	0.211
Teaming, $49\frac{1}{4}$ cts. per short ton.....	0.009
Miscellaneous items	0.008
Total	\$0.815

The working force was as follows:

1 foreman, at \$2.50 per 10-hr. day.....	\$ 2.50
2 sub-foremen, at \$2.00.....	4.00
9 men in pipe gang (including 2 calkers), at \$1.75.....	15.75
32 laborers digging trench, at \$1.50.....	48.00
12 laborers backfilling, at \$1.50.....	18.00
1 waterboy, at \$1.00.....	1.00

Total, 423 lin. ft., at \$0.211.....\$89.25

At times the back filling gang was engaged in trench digging. Trenches were 5 ft. 2 ins. deep. The digging ranged from the easiest spading to the hardest picking, the average being "average earth." Could the contractor have been present all the time, the cost might have been less. The backfilling was done by hand, and it was not rammed, but the trench was flushed with water. No material was hauled away. The work was done in August and September, 1903, and there was very little rain. It was not necessary to brace the trench except at a few spots.

Cost of Water Main and Service Pipe Laid in a Southern City.—

Mr. C. D. Barstow gives cost of shallow trenching and pipe laying in a southern city, where negro laborers were used. From the data given by him I have compiled the following tables of cost:

For the most part the trenches were 15 ins. wide at bottom and 20 ins. at top, and 3 ft. deep. Some trenching was done using a team on a drag scraper, 20 ins. wide; then the trench was made 3 ft. wide at top. Using teams was more economical, as may be seen by comparing C with D in the foregoing table. After a rain, however, the scrapers could not be used to advantage. In using a plow for loosening the earth, several feet of chain are fastened to the end of the plow beam, and one or more men ride the beam: in

this way plowing may be done in a trench 4 ft. deep, one horse walking on one side and one on the other side of the trench. A blacksmith was kept busy sharpening about 60 picks a day. There was a night watchman. The pipe was distributed by contract at 34 cts. per ton.

TABLE OF COST OF TRENCHING AND PIPELAYING IN THE SOUTH.

Wages per 10-hr. day for negro laborers, \$1.25; for calkers, \$1.75; for white foremen, \$3.00; for teams, \$3.25; for horse ridden by boy, \$1.50.

Job	A.	B.	C.	D.	E.	F.

*Backfill with drag scraper.

¹Trenching in an old street, 1,200 ft. in very muddy ground. Two rainy spells in 18 days of work. Then 10-in. pipe was laid for 3,440 ft.; then 4,038 ft. of 12-in. pipe were laid for 1 1/4 cts. per ft. less than it cost for the 10-in. pipe; then 3,270 ft. of 8-in. pipe were laid for 2 1/4 cts. per ft. less than it cost for the 10-in.

²Cemented clay and gravel requiring hard picking. Frequent rains.

³The backfilling and tamping were done most thoroughly, a stretch of 2,550 ft. requiring 2 days for 30 men.

⁴Sand and loam, bottom land, very easy digging.

⁵Very easy shovelling and no tamping. 11 men 7 days backfilled 9,620 ft. of trench.

⁶Drag scrapers used to backfill; boy riding horses to tamp, gang 22 men, 3 teams, 1 boy and horse, 2 days on 5,447 ft.

⁷Backfilled 1,670 ft. in one day by 19 men, using 1 boy and horse on tamping.

⁸Half the pipe was 3-in. at cost here given, half was 6-in. costing 1/2-ct. less per ft. for laying.

⁹Ground wet and often muddy. Backfilling 11,433 ft. done by 12 men and 2 teams on scrapers in 7 days; no tamping.

The lead and yarn consumed per foot of pipe (pipe in lengths of 12 ft.) was:

1.3 lbs. of lead and .04 lb. of hemp for 12-in. pipe.

.96 lb. of lead and .04 lb. of hemp for 10-in. pipe.

.95 lb. of lead and .03 lb. of hemp for 8-in. pipe.

.66 lb. of lead and .03 lb. of hemp for 6-in. pipe.

Some 6,000 ft. of 2-in. wrought-iron service pipe was laid in

trenches 2 ft. deep, at a cost of 1.9 cts. for trenching, 0.24 ct. for laying pipe, and 0.71 ct. for backfilling—there was no tamping done.

For a distance of 372 ft. a trench 2 ft. wide and 3 ft. deep passed through a street paved with brick laid on $7\frac{1}{2}$ ins. of concrete. The brick was removed for a width of 3 ft. and the cost was as follows:

	Men, days	Cts. per lin. ft.
Removing brick and concrete—Foreman.....	0.5	
Laborers	7.0	2.61
Excavating trench—Foreman	0.5	
Laborers	18.0	6.30
Backfilling and tamping well—Foreman.....	1.0	
Laborers	10.6	4.09
Labor relaying concrete	7.8	2.61
Labor relaying bricks.....	4.5	4.59
Professional brick pavers.....	4.0	
Professional brick helpers.....	2.0	
Hauling away 23 loads surplus earth.....		1.23
15 cu. yds. sand cushion.....		4.02
1,700 new bricks		6.92
18½ bbls. cement to relay concrete.....		6.20
Total		38.58

Cost of Hauling, Distributing and Joining Wrought Iron Pipe in Maryland.—Mr. L. B. Abbott, Chief Engineer The Consolidated Coal Co., Frostburg, Md., gives the following cost for hauling, distributing and joining pipe, in the construction of an 8,000-ft. long pipe line. The work was done in connection with the installation of a water supply for one of the mines of the above-mentioned company.

The pipe, consisting of 4,000 ft. of 6-in. and 4,000 ft. of 8-in. double-strength, wrought-iron pipe, was hauled a distance of eight miles over roads that had to be practically rebuilt in many places. From the main road to the pumping station, a distance of $\frac{1}{2}$ mile, a new road had to be cut and graded for the heavy loads to be hauled over it. It took five days to haul the pipe to the two distributing points, from 12 to 15 teams being used, each team making one trip a day. Teams were paid for at the rate of \$4.50 per day for a 2-horse team. The 4-horse teams, of which there were but two or three used per day, were furnished by the company, and charged at the rate of \$8 per team. The teams started to load at 7 o'clock, and by time the 12 or 15 teams were loaded it was generally 10 o'clock. It took from four to five hours to go to the distributing points. It was found that a 2-horse team hauled five lengths of pipe, or about 96 ft. per load, while a 4-horse team hauled nine lengths, or about 170 ft., nine lengths being all that could be loaded into the wagon. The cost of hauling the pipe a distance of eight miles was 4.7 cts. per lineal foot.

From the distributing points a team dragged each length of pipe to its place in the line, the average cost of distributing being nearly 1 ct. per foot.

*Engineering-Contracting, Oct. 17, 1906.

While the pipe was being distributed a force of 12 men started to join it up. The men joining and distributing pipe worked about eight hours per day. The greater part of the time they drove to their work. The joining gang was paid as follows: One man at \$2.25; three men at \$2.20, and eight men at \$1.75 per day. The pipe was not buried, but was blocked up about a foot from the ground. The entire 8,000 ft. was laid in ten days. In many places the ground was very rough, and cribs 6 and 7 ft. high had to be built to hold the pipe. The average cost to lay and block up the pipe was 2.9 cts. per foot. This included putting in stay rods every 300 or 400 ft. to keep the pipe from jumping when the pump was running, and the placing of drain cocks in all low places.

Cost of Taking Up an Old Pipe Line.—Mr. E. E. Fitzpatrick furnishes the following data relative to taking up more than 8 miles of pipe line at Greenburg, Kansas. There were 10,200 ft. of 4-in. pipe; 4,310 ft. of 6-in.; 2,050 ft. of 8-in., and 890 ft. of 10-in. After digging the trenches, the 8-in. and 10-in. pipes were raised a little, and fires built under the joints until the pipe expanded; then the pipes were unjointed by working them up and down with a three-leg derrick. The 4-in. and 6-in. pipes were raised bodily in long sections onto the bank, heated a little, and unjointed by means of jack-screws and clamps. The time required to do all the trenching, backfilling and unjointing, was equivalent to the work of 1 man for 428 days; and, assuming wages at \$1.50 a day, the cost was only 3½ cts. per foot of pipe.

Cost of Constructing and Laying Cement Lined Water Pipe, Plymouth, Mass., and Portland, Me.*—Two general methods of building wrought-iron, cement-lined pipe have been used in this country; the first, known as the Goodhue & Birnie pipe, the second, known as the Phipps patent.

The Goodhue & Birnie pipe was generally made by riveting up sheets of wrought iron, single riveted with cold rivets, without any attempt to make the joints water-tight, and lining this wrought-iron shell with from ¾ to 1 in. of neat Rosendale cement, or cement mortar mixed 1 part of cement to 1 part of sand. This work was generally done in a central plant, or at different points along the pipe line, from which the pipe was carried to the trench, there imbedded in Rosendale cement mortar laid along the bottom of the trench, and then covered over the sides and top with a ¾ to 1-in. layer or casing of Rosendale cement mortar plastered on with rubber gloves or trowel in the hands of the pipe maker. The trench was generally backfilled immediately or shortly after laying the pipe.

The pipes were made in lengths of 9 ft., and the joints between the pipes were made by means of a sleeve of wrought iron with inner and outer casing of cement, or by making the pipe tapering so that the end of one pipe was fitted into the end of the next. In the

*Extract from a paper by Leonard Metcalf, M. Am. Soc. C. E., presented to the New England Water Works Association, Dec. 9, 1908, and reprinted in *Engineering-Contracting*, Apr. 7, 1909.

larger mains the joints were often plastered on the inside after laying; in the smaller ones, this was, of course, not attempted.

The Phipps patent pipe was generally made and coated without as well as within with a $\frac{3}{4}$ to 1-in. layer of cement or cement mortar, the outer coating being held in place by a thin sheet of wrought iron which subsequently rusted out in the trench. This outer sheet was of distinct advantage, however, as a protection to the outer cement coating in the handling and laying of the pipe.

In a few cases cast-iron bells and spigots have been riveted to the wrought-iron sheets before making the pipe, and the joints have then been made in the ordinary manner with lead tightly calked in place or by the use of cement mortar.

More recently under the Phipps patent, a type of cast-iron ring has been developed which is driven home in each end of the pipe,—one of the rings being a female ring, the other a male ring—thus more rigidly holding the end of the pipe and preventing injury to it in transportation and laying, and incidentally making more convenient the placing of the outer cement coating of the pipe, which is made of grout poured into the mold between the inner and outer sheets, with the pipe standing on end. The joint between pipes is made finally by the use of a sleeve as heretofore.

So far as the writer is aware no cast-iron has thus far been developed which has proven thoroughly satisfactory and advantageous from the standpoint of economy.

It is perhaps worthy of note that while blue enameled wrought-iron sheets imported from England were used in many of the early installations, in making the later ones steel has been substituted at some saving in cost, though not in durability.

Plymouth, Mass.—Plymouth is a town of about 11,000 inhabitants and has had a water supply since 1776. Until 1855 the water was supplied to the town by a private company and the pipes used were wooden logs with holes bored in them. In 1855 the town purchased the plant from the company, and the use of cement-lined pipe dates from that period.

At that time about 18,000 ft. of 10-in. pipe was laid and several thousand feet of 8-in., 6-in. and 4-in. pipe were laid for the distribution system. Practically all of the pipe laid at that time is still in use.

The pipe as then manufactured consisted of a sheet-iron shell about 9 ft. in length, lined on the inside with about $\frac{1}{2}$ in. of cement mortar, composed of cement and sand in proportions of 1 to 1. The pipe was then laid in a bed of cement mortar in the trench, ends butted together, with a steel sleeve or collar at each joint. The top and sides of the pipe were then covered with two or more inches of cement mortar, all of the same proportions as used for the lining, and a cement-mortar joint was made at each joint of the pipe.

This pipe is still in use and withstands a varying pressure in different sections, from a few pounds to about 50 lbs.

In 1900, somewhat over 40 miles of pipe from 4 to 30 ins. in

diameter was in use. At this time a change in the method of making the pipe was introduced, and for the past seven years all extensions have been made with a pipe manufactured in the local water-works shop, which is furnished with mechanical devices and power machinery necessary for economical manufacture.

The following description will make the present method of construction clear. The pipe consists of a shell, a jacket, male and female rings, and sleeves. The shells and jackets are of soft steel and are received at the shop in flat rectangular sheets of proper size and gage. For the shells of 18-in. pipe about 30 tons of steel sheets of No. 13 gage were used, at a cost of about \$50 per ton for the sheets.

The gage of the sheets used for the shells of pipes of different sizes is as follows:

24-in.....	12 gage	10-in.....	17 gage
18-in.....	13 gage	8-in.....	18 gage
16-in.....	13 gage	6-in.....	19 gage
12-in.....	15 gage	4-in.....	20 gage

The jackets are all No. 26 gage iron. The operation of making the pipe is as follows:

The shells are punched in a punching machine. The spacing of the rivet holes is $\frac{3}{4}$ -in. c. to c., the edge of the rivet hole being $\frac{1}{2}$ -in. from the edge of the sheet. The sheets are then put into the rolls and given a semi-circular form, as two sheets are used for the manufacture of one shell for the 18-in. pipe. After being rolled, the shells are riveted by hand, using 816 rivets with a $3\frac{1}{2}$ -lb. hammer, on a stake, so-called, which is simply a bar of iron about 10 ft. long, the upper surface of which is curved to approximately the same radius as the shell of the pipe which is to be riveted. The jackets are punched, rolled and riveted in precisely the same manner as the shells and are $1\frac{1}{2}$ ins. larger in diameter.

The rings are of cast-iron, a male ring for one end of the shell and a female ring for the other, the female ring being concave and the male ring convex, thus enabling a very tight joint to be made when the pipes are fitted together in the trench. About thirty tons of these rings were used in the manufacture of 16 and 18-in. pipe during the past year and the cost of the rings was 4 cts. per lb.

The next operation, after the shells are riveted, is the fitting in of the rings, and as they are made just for a driving fit into the shell they are driven in by use of the maul. After the rings are in place the shells for the 18-in., 16-in. and 14-in. pipes are lined by hand, and the smaller sizes of shell from 12-in. to 4-in. are lined by means of a revolving cone. Neat Rosendale cement is used in lining. About 3,000 bbls. of cement have been used during the past year in the manufacture of pipe, and the cost was \$1.20 per bbl., delivered at our shop.

When the shells are ready to be lined by hand they are placed horizontally on two horses. A man stands at each end of the pipe with a long-handled pallet knife, so-called, to spread the cement smoothly in the pipe. This knife is simply a flat blade about $1\frac{1}{2}$ ins. wide and 4 ins. in length, with a handle about 4 ft. long. The

cement for lining is mixed by hand in mixing boxes, and there are two men to mix for the two men who line. As the pipe lies on the horses it is lined for its whole length and half way up each side. Then the cement is allowed to set, after which the pipe is rolled over and the remaining half lined. After the cement has been smoothly spread about $\frac{1}{2}$ -in. thick, on the inside of the pipe, and irregularities which appear are corrected by the use of the "nigger-head," which is a stiff brush on the end of a long handle. This brush in the hands of a skillful workman can bring the interior of the cement pipes to a very smooth surface.

At this point it may be well to describe the operation of lining the smaller sizes of pipe. The shells having been punched, rolled and riveted, and rings put in in precisely the same manner as previously described, are stood upright on an elevator which descends into a pit. In this pit is the cone, so-called, which has an external diameter equal to the internal diameter of the shell when lined—in other words, about an inch smaller in diameter than the shell—placed and held directly over it on the elevator. The cone revolves on a vertical axis and cement mixed by machinery is put in at the top of the shell as it stands on the elevator over the cone. The top of the cone, extending for a few inches into the bottom of the shell, holds the cement from falling through into the pit. The elevator holding the shell is then lowered and the cone revolving at the same time spreads the cement smoothly and uniformly on the inside of the shell.

The next operation is filling and grouting the pipe. The shells are stood on end around the edge of a platform which is about 6 ft. above the floor. A clamp is placed around the bottom of the shell about 8 ins. from the lower end, and the jacket lowered from above fits into the clamp at the bottom. The jacket is kept symmetrical with the shell at the bottom by means of this clamp, and at the top by means of four wedges. The grout is merely a mixture of neat cement and water, mixed to such a consistency that it will pour readily, and is mixed by machinery in a cylindrical mixer which has four paddles. After being thoroughly mixed, the grout is poured into a metal bucket which is suspended by a chain with a wheel and is carried on a track around the platform. The grout is poured from the bucket between the shell and jacket of the pipe that has been stood around the edge of the platform. After the grout has been poured, the pipes are allowed to set twelve hours, when the cement is usually hard enough to permit of handling them. The pipes are then loaded upon a truck, taken to the yard, cleaned, and painted with a coal-tar paint. After staying in the yard about two weeks they are sufficiently hard to permit of being loaded upon a wagon and carted to the trench.

Tables VI and VII show respectively the cost of making and laying the largest cement-lined pipes which have been made at Plymouth. Town labor, only, is used, and \$2 is the wage paid for a working day of eight hours, for each laborer. The foreman receives \$3.

The pipe-making gang numbers about 16 men, but only 4 are

kept on the regular gang and the others are hired as they are needed.

Portland, Me.—In the years 1868-9 the Portland Water Co. laid a 20-in. wrought-iron cement-lined supply main, about 15.2 miles long, from Sebago Lake to the city of Portland. Data as to the cost of this main are unfortunately lacking.

In the years 1875-9, however, a second wrought-iron cement-

*The contract price at ordinary depths of cut, and exclusive of rock, was 70 cts. per lin. ft. The difference, 78 cts. per ft., represents the additional allowances for extra depth and for rock and for tunnel, and for all contingencies because of the character of the ground. These additional costs would naturally be somewhat higher on the 26-in. line than on the 24-in. line, and the route of the 20-in. line covers substantially the same space as that occupied by both the 26-in. and 24-in. lines.

lined supply main was laid from the lake to the city. The upper portion of this, approximately $3\frac{1}{2}$ miles in length, was 26 ins. in diameter; the lower portion, approximately 11.4 miles in length, 24 ins. diameter. The actual cost of this compound main was fortunately developed from the books of the company and is given in Tables VIII and IX, as some of the unit costs to be derived therefrom are interesting and valuable.

It should be stated that the static pressures upon this supply main are approximately as follows.

4 miles, under	0—40 lbs. per sq. in.
2.7 miles, under	40—60 lbs. per sq. in.
4.9 miles, under	60—80 lbs. per sq. in.
2.3 miles, under	80—100 lbs. per sq. in.
0.9 miles, under	100—120 lbs. per sq. in.

The main is stated to have been built with a factor of safety of approximately 3, but the computation of the factor of safety under several assumed heads indicates that the actual factor of safety is probably not in excess of 1.5 at the points of maximum pressure, assuming always static pressures, and ignoring alike the decrease in pressure due to friction and the increase in pressure due to water hammer or other causes.

The cost of this 26-in. pipe line was excessive, owing to deep cut work, a considerable amount of which was in quicksand.

Mr. Allen Hazen, who was one of the engineers retained by the Water District in the valuation of the Portland waterworks, made the interesting analysis of these items of cost given in Table X.

Cost of Lining Iron Service Pipes With Cement.—Mr. Fayette F. Forbes gives the following relative to lining wrought iron service pipes with cement. The pipe is bought in short lengths, 18 ft., and is 1 to 2 ins. diam. before lining. The lining reduces the diameter a little less than $\frac{1}{4}$ in. Such pipes have given perfect satisfaction for 25 years in Brookline, Mass. In 1900 the cost of lining a 1-in. pipe was $1\frac{1}{2}$ cts. per ft., a 2-in. pipe, 3 cts. per ft. A gang of 6 men will line 4,000 to 5,000 ft. of 1-in. pipe per day. The gang is as follows:

- 1 man mixing cement.
- 1 man filling press and overseeing.
- 1 man working pipes to the press and from the press to the coning frames.
- 2 men (one at each end of pipe) doing the coning.

In 1898 the cost of labor and cement for lining 9,000 ft. of 1-in. and 3,000 ft. of 2-in. pipe was as follows:

Labor:

Preparing pipes	\$65.79
Cementing	66.63
Grouting	22.66
Reaming	37.98

Materials:

23 bbls. natural cement at \$1.10.....	25.30
Coal for heating shop	6.00

Grand total\$226.38

Which gives 1.5 cts. per ft. for lining the 1-in. pipe, and 3.03 cts. per ft. for the 2-in. pipe.

A barrel of cement will line and ground the following lengths:

1-in. pipe, 700 ft.

1½-in. pipe, 500 ft.

2-in. pipe, 300 ft.

Extreme care must be used to get uniformly good results. The following methods are best: Use wrought iron pipe in 16 ft. lengths. Straighten all bent pipes. Remove couplings, turn them around and screw on the other end, to avoid trouble in putting lengths together. Examine for defective welds. Run a cutting tool through pipe to remove scale, dirt, and projections of iron from the welds. Use American natural cement for lining (Portland is too heavy), and use it neat. Sift all cement to remove pieces of unground rock, wood, paper, etc. Use cement quickly after wetting. One man mixes cement and water, preparing only enough for 8 pipes at a time, and constantly working it over to keep at right thickness. If any of the batch is left over, throw it away. The pipes are filled full of the cement mortar, using a press made by the Union Water Meter Co., of Worcester, Mass., who also make the cones and other tools. Cones are passed through the pipe twice, and the cement that is pushed out is used in the next pipe, except that from the last pipe filled by the batch of cement, which is thrown away. While the cone is being drawn through, the pipe is slowly revolved to keep the cone as nearly in the center of the pipe as possible. However, results are satisfactory even if the lining is quite uneven in thickness. The cones are washed after each pipe is lined. Before the cones are drawn through, a piece of pipe 12 to 18 ins. long is screwed to each end of the pipe to be lined, to ensure a perfect lining at the ends. After the pipes have been lined 3 to 5 days, until the cement is quite hard, a thin grout of cement is run through them, by elevating one end of the pipe and pouring the grout in. A rubber cone is then drawn through, leaving a smooth, impervious lining. The ends of the pipe are then reamed out to fit the composition ferrules, and the threads are cleaned. Ferrules are made of best steam metal, ½-in. diam. on the inside (for a 1-in. pipe). Double ferrules are used where pipes are screwed together, and single ferrules for connections at the main. These pipes can be bent without damage to the lining, if care is used.

Cost of Setting Meters and Laying Service Pipes.*—Mr. W. H. Shillinglaw gives the cost of setting water meters during 1908 by the Water Works Department, Brandon, Manitoba, as follows.

Crown meters	¾ in.	1 in.	1 in.	1½ in.
No. of meters set.....	499	20	5	2
Cost of labor	\$295.85	\$20.55	\$5.97	\$2.60
Cost per meter	0.593	1.02	1.20	1.30
Cost of materials	145.73	10.24	1.84
Cost per meter	0.282	0.51	0.37
Total cost per meter.....	0.875	1.53	1.57

*Engineering-Contracting, Jan. 20, 1909.

These meters were all set in basements by day labor by city employes. The cost for $\frac{1}{2}$ -in. meters varied from 20 cts. to \$2 for labor. A large number of these meters were installed on old services and entailed considerable alteration in service pipes and additional expense. The cost of setting meters on new services varied from 20 cts. to 50 cts. for labor.

The cost of laying water service pipes during 1908 was as follows:

	$\frac{1}{2}$ inch.	$\frac{3}{4}$ inch.
No. of services	92	7
No. of feet laid	3,051	296
Cost of labor	\$1,030.73	\$ 96.69
Cost per ft.	0.34	0.323
Cost per service	11.38	13.81
Cost of supplies	857.38	121.90
Cost per service	9.32	17.41
Average length of service, feet.....	33	41

These services were laid in 10-ft. trenches in sand, gravel, some dry and a considerable number very wet and requiring pump-

ing. Refilling was well rammed. The cost of labor includes making up service, tapping main, etc. All work was done by day labor by city employees. The cost of labor varied from 26 to 50 cts. per lin. ft. The $\frac{3}{4}$ -in. services were all made up for two $\frac{1}{2}$ -in. branches to serve two premises.

The form employed for reporting costs is shown in Fig. 6; this form was used for both services and meters, the foreman simply filled in the proper words.

Cost of Meters and Setting, Cleveland, O.—Mr. Edward W. Bemis gives the following relative to the cost of setting $\frac{3}{4}$ -in. Trident meters in Cleveland, Ohio, during 1903. Some 20,000 meters of this size had been set during 1902 to 1903 inclusive. A $\frac{3}{4}$ -in. meter costs \$6.50, and the cost of setting 13,400 meters in 1903 averaged \$6.87, making a total cost of \$13.37. These meters were set as follows:

857 meters in brick vaults.

3,174 meters in basement settings.

9,378 meters in sewer pipe settings.

The cost of these different types of settings was as follows:

<i>Sewer Pipe Setting.</i>	
4 ft. of 15 in. sewer pipe.....	\$1.46
Frost cover	0.18
Ring and cover	1.42
2 ells	0.12
2 couplings	0.08
7 ft. of $\frac{3}{4}$ -in. pipe	0.86
Labor	4.01
Total	\$7.62
<i>Basement Setting.</i>	
Brick	\$0.12
Cement	0.05
Cover	0.30
Fittings	0.25
Labor	3.23
Total	\$3.95
<i>Brick Vault Setting.</i>	
\$50 brick	\$2.45
1 $\frac{1}{2}$ sacks cement	0.38
2 couplings	0.08
2 ells	0.12
1 nipple	0.06
1 union	0.24
1 ring and cover	3.21
Labor	2.92
Total	\$9.46

One meter reader is employed for every 1,000 meters, and he is accompanied by a laborer, when reading meters, to turn off the water where there appears to be waste, while the meter reader waits at the meter to detect running water. Each meter is read every 6 weeks from Mar. 1 to Dec. 1. The cost of operation per meter was as follows in 1903:

Interest and depreciation, estimated at 8% of \$13.37.....	\$1.07
Reading meters and clerical work	1.10
Total	\$2.27

The prices of meters were:

$\frac{5}{8}$ -in. meter	\$6.50
$\frac{3}{4}$ -in. meter	9.45
1-in. meter	13.50

The gang for basement setting is composed of 4 meter setters (at 27½ cts. per hr.), and 4 laborers (at 21 cts. per hr.), and a horse and vehicle with driver (at 30 cts.), under a foreman (at 42 cts.). These men work in pairs, 2 men at each meter, and set a meter in 4 hrs. on the average, the range being 1 to 6 hrs., depending on the arrangement of the plumbing, etc. The opposition of plumbers to the use of laborers and meter setters was overcome by employing plumbers to wipe all lead joints. The cost of setting meters in 1907 was as follows:

	No. set.	Av. cost.
$\frac{5}{8}$ -in. meter in basement	2,929	\$ 4.22
$\frac{5}{8}$ -in. meter on sewer pipe.....	1	5.00
$\frac{5}{8}$ -in. meter in brick vault.....	4,368	13.47
$\frac{3}{4}$ -in. meter in basement.....	14	6.44
$\frac{3}{4}$ in. meter in brick vault.....	9	18.01

2-in. meter in basement	6	9.96
2-in. meter in brick vault.....	27	21.97
3-in. meter in basement	3	30.71
3-in. meter in brick vault.....	10	31.36
4-in. meter in basement.....	2	22.83
4-in. meter in brick vault	8	46.78
6-in. meter in brick vault.....	1	58.01

Cost of Setting Meters and Maintenance, Rochester, N. Y.—Mr George W. Rafter gives the following relative to the cost of setting and resetting meters and their maintenance in Rochester, N. Y. The cost of setting 11,500 new meters, during 1893 to 1905, averaged \$3.24 per meter, although there were many years when the average was \$2.25 or less. The cost includes the proportionate part of the salary of superintendent and meter clerk, and, as the average was only 800 new meters set per year, this element of cost would naturally form a large percentage of the total.

About once in 12 years a meter has to be removed and repairs made. The cost of removing, repairing and resetting 11,000 meters averaged \$4.80 per meter, which is equivalent to about 40 cts. per year per meter. This does not include the cost of current maintenance and inspection of meters in place, which averaged 37 cts. per meter per year for 12 years, although during the last 6 years it averaged only 14 cts. per meter per year, the year of 1904 being only 9 cts. per meter.

The first cost of each meter appears to have been about \$10. From this it appears that repairs and resetting have averaged 7.7% (77 cts.) of the first cost of each meter per year.

During the year 1905, there were 36,100 meters in use in Albany, Kansas City, Lowell, and Rochester, and 4,100, or 11%, of these were removed, repaired and reset.

Cost of Operating and Maintaining Meters, Reading, Pa.*—The cost of operating and maintaining the meter system of Reading, Pa., for the fiscal year ending April, 1908, was \$3,563.12, for an average of 2,012 meters in service. This is at the rate of \$1.77 per meter per year; in the preceding fiscal year the rate was \$1.75 per meter. The unit costs for the several sub-divisions of operation and maintenance are given by Mr. Emil L. Nuebling, superintendent and engineer of water works, as follows:

Repairs	\$0.878
Clerical service553
Reading193
Delivering bills087
General test039
Sundry work016
Stationery, etc.009
Total	\$1.774

The cost of repairs increased 84 per cent over the previous year, due principally to extensive repairs to large meters. All other costs were lowered considerably.

Cost of Placing Hydrants, Chicago.† — The standard hydrant adopted by the city of Chicago is the Creiger; it constitutes about 80 per cent of the total number of hydrants in use in that city. These hydrants are made by the city at its own shops. The following data relate to the placing of several double hydrants of the above type, the work being done in 1906 by city forces. The costs include excavating for the connection with the main, excavating for the hydrant base, placing hydrant, backfilling, and making the connections. The trench as a usual thing averaged about 5 ft. in depth. The wages of labor per 8-hour day and cost of materials were as follows:

	Per day.
Assistant foreman	\$3.62
Timekeeper	3.50
Calker	3.00
Laborers	2.50

Double teams were hired at the rate of \$4.50 per day. Single teams were usually furnished by the city and charged for at the rate of \$1 per day.

The prices paid for materials were as follows:

Pipe, 6 in.	49c per lin. ft.
Lead	6 1/2 c per lb.
Gaskets	5c per lb.
Coal	1 1/4 c per lb.
Special castings	2 1/2 c per lb.

The coal was used in the furnace for melting the lead for the joints.

The excavation was in sand, and was easy digging.

Cost of Concrete Vaults for Valves.*—Mr. Carroll Beale gives the following:

The system of concrete construction for valve casing foundations described and illustrated here has been in successful operation in the District of Columbia for nearly a year. The foundation, Fig. 7, consists of concrete rings 3 ft. in diameter, 8 ins. and 4 ins. high, 3 ins. thick and reinforced with 16-gage expanded metal. These rings have proven to be not only more economical than the old brick construction, but the department is now enabled to build a foundation in five minutes, whereas with the brick construction one whole day was required by a bricklayer and his force to construct a foundation 4 ft. deep.

To illustrate the economy of these rings, take for example a masonry foundation 4 ft. deep of brick. This required the services of a bricklayer and force one day of eight hours. The bricklayer's force account and material used were as follows:

1 bricklayer at \$5 per day.....	\$ 5.00
2 laborers at \$1.75 per day.....	3.50
Cart and driver \$2.25 per day.....	2.25
420 red brick at \$9 per M.....	3.78
1/2 bbls. of Portland cement at \$1.79.....	1.31
1/2 cu. yd. sand at \$1.20.....	0.40
Total	\$16.24

**Engineering-Contracting*, Nov. 18, 1908.

For a 4-ft. foundation of concrete, six 8-in. rings are required. These rings in place cost 50 cts. each, therefore the cost would be \$3, as against \$16.24 for the brick construction. It is therefore demonstrated that the cost of the concrete foundation is less than 20 per cent the cost of the old brick construction, not taking into consideration the time lost by the bricklayer in moving about the city.

The ring, 8 ins. high, cares for a height formerly occupied by

Eng. Contr.

Fig. 7.—Concrete Vault.

6 sq. ft. of brickwork 9 ins. thick, or 72 brick, which at \$9 per M is equal to 65 cts., so it may readily be seen that the cost of these rings is less than the cost of the brick alone without mortar and without labor, which last item amounted to \$10.75 per day current expense.

An itemized cost of the rings is as follows:

0.0767 bbl. of cement = 1/13 bbl.

0.048 cu. yd. gravel = 1/20 yd.

0.024 cu. yd. sand = 1/40 yd.

The cost of one ring therefore is:

	Cts.
Concrete	25
Labor	7
Steel	16
Total	48
Placing	2
Total for ring in place.....	50

Fig. 8.—Cast Iron Forms.

To sum up the relative merits of the brick and concrete construction the use of concrete saves the department a current expense of \$10.75 per day, avoids the delays attending brick construction, is as readily removed as the brick, and is much stronger.

These rings are made in the cast-iron forms shown by Fig. 8, on a smooth platform, and one man is able to make four 8-in. rings in one hour.

As illustrative of the economy in reinforced concrete vault construction, the accompanying drawings, Figs. 9 to 11, and Table XI, give examples of the types of vaults now being constructed in the

District of Columbia. Three of these vaults, 5 ft. 10 ins. by 5 ft. 6 ins. by 11 ft. 7 ins., 5 ft. 9 ins. by 5 ft. by 9 ft., and 4 ft. 2 ins. by 8 ft. 10 ins. by 6 ft., have just been completed at New Jersey Ave. and B St., just north of the United States Capitol, at a cost of \$50 each, excluding the cost of the lumber which will be reused. The roofs of these vaults have an ultimate strength of about 3,500 lbs. per sq. ft., and the flat construction permits of at least 2 ft. more

Fig. 9.—Concrete Vault for Horizontal Valve.

This last is a very important item where the mains are shallow head room than can possibly be had where a brick arch is used, and where every inch of head room counts. The vaults may be constructed for approximately one-third the cost of the brick vaults and have a much greater factor of safety than the old brick vaults using 12-in. walls. The drawings and tables explain fully the method of construction without further description.

Cost of Dipping Pipes.—In a very interesting article by Thomas

H. Wiggin, in the Journal of the Association of Engineering Societies, 1899, Vol. 32, on the Manufacture and Inspection of Cast-Iron Pipes, the following data are given as to the cost of dipping pipes. To coat one 12-ft. length of 48-in. cast-iron pipe costs approximately as follows for different coating materials:

3½ gals. crude tar at \$3 per bbl. of 52 gals.....	\$0.22
5 gals. pitch at \$5 per bbl. of 52 gals.....	0.50
1½ gals. tar varnish at 10 cts.....	0.15

The first two are applied by dipping, but the tar varnish is applied with a brush.

Rusty pipes will not hold a coating.

Fig. 10.—Concrete Vault for Vertical Valve.

Cost of Cleaning Water Pipe, Pittsburg, Pa.—Mr. J. D. Underwood gives the following: An 8-in. cast-iron water pipe at Pittsburg became coated with 0.32 in. of scale during 14 yrs. of use so that the pressure at the end was 34 lbs. below the theoretical static head. The contract price for cleaning 3,300 ft. of pipe was 24 cts. per ft., at which price the contractor made a very large profit, as will be seen from the following data.

The pipe was cleaned in lengths averaging about 800 ft., the range being 400 to 1,200 ft. depending on local conditions. The pipe was cut at intervals of 800 ft. (average), and a special Y

connection inserted, into which the cleaner could be introduced. These special Ys are so made that a cover can be bolted to them, should an emergency arise necessitating putting the pipe line into service. In order to get a wire cable through the pipe, a "go-devil" is first run through. It consists of two cones on an iron rod, each cone about 12 ins. long, and spaced 3 ins. apart. The cones are inserted blunt end foremost. To the "go-devil" is fastened a No.

Fig. 11.—Concrete Vault for Vertical Valve.

22 flexible wire cable. The water is turned on and forces the "go-devil" through the pipe to the next special Y. The water is then shut off and a $\frac{3}{8}$ -in. wire cable is drawn back through the pipe by means of a one-man winch. The cleaner, or scraper, is fastened to the cable and is drawn through the pipe by a four-man winch, the water washing the broken scale out of the pipe ahead of it.

The time required to clean an 800-ft. section was as follows:

	Mins.
Running the "go-devil" through.....	3
Pulling cable through.....	38
Pulling cleaner through.....	48
Total	89

The following gang was engaged for 6 days, the wages being assumed:

	Per day.
7 laborers at \$1.50.....	\$10.50
1 mechanic	3.50
1 foreman	5.00
Total	\$19.00

The labor, therefore, cost less than \$120 for 3,300 ft. cleaned, or less than 3.7 cts. per ft. It is stated that even this cost could have been cut almost in two had it been possible to shut off the water continuously, but, as the pipe line was the main source of water supply for a considerable district, the water had to be turned on at intervals, delaying the work 2 or 3 days.

Cost of Cleaning Water Pipe, Halifax.—Mr. E. H. Keating gives the following costs of cleaning water pipes in 1881 at Halifax, Canada.

A 24-in. main, 19 yrs. in use, and 13,400 ft. long, was cleaned for 4.4 cts. per ft., the items being:

Labor	\$121
Materials, including scraper.....	337
Manholes of brick and stone.....	139
Total	\$597

A 20-in. main, 13 yrs. in use, and 6,000 ft. long, was cleaned for 5.4 cts. per ft., the items being:

Labor	\$ 85
Materials, including scraper.....	193
Manholes of stone.....	48
Total	\$326

A 15-in. main, half 13 yrs. and half 25 yrs. old, 29,500 ft. long, was cleaned for 1.7 cts. per ft., the items being:

Labor	\$248
Materials, including scraper.....	162
Manholes	84
Total	\$493

A 12-in. pipe, 19 yrs. in use, 3,700 ft. long, was cleaned for 4.9 cts. per ft., the items being:

Labor	\$ 24
Materials (not including scraper, but including 2 batch boxes).....	50
Manholes	99
Total	\$173

All told, some 62,800 ft. of 24, 20, 15 and 12-in. pipe were cleaned at a cost of \$1,769, or 2.82 cts. per ft., not including cost of man-

holes, which amounted to \$439, or 0.7 ct. per ft., additional, making a total of 3.52 cts. per ft.

Manholes and "hatch boxes" were built at intervals to insert the cleaners, which were scrapers provided with pistons, driven through the pipes by water pressure.

The incrustation on the pipes was $\frac{3}{8}$ to $1\frac{1}{4}$ ins. thick.

Cost of Cleaning Water Pipe, St. John, N. B.—Mr. Wm. Murdoch gives the following relative to the cost of scraping water pipe at St. John, N. B., in 1897:

Special iron "hatch boxes," were made, consisting of short lengths of cast-iron pipe, provided with a flanged opening and a flanged cover, bolted together. Through the "hatch," or opening, the scraper was inserted or removed. There were 9 "hatch boxes" in 4.3 miles of 24-in. pipe. Each box weighs 3,300 lbs. and costs \$157. Hence the first cost of these hatch boxes was \$350 per mile of pipe, or nearly 7 cts. per ft.

The scraper weighs 263 lbs., and consists of an iron shaft about 6 ft. long, made of a 3-in. wrought-iron pipe, at the front end of which is the scraper, and at the other end a "piston"; there is a second piston at the middle of the shaft. The scrapers are 12 steel blades, arranged in two sets of six each, one set back of the other on the shaft. The blades are bent back and are springy enough to pass over such obstructions as cannot be removed. This scraper cost \$40. It was forced through the pipe by the water pressure. To remove an incrustation about $\frac{3}{4}$ in. thick required 22 trips of the scraper, and the labor cost of cleaning the 4.3 miles of 24-in. pipe was \$64 per mile, or 12 cts. per ft. The working force consisted of:

- 6 men (at the valves).
- 1 mechanic.
- 2 men (watching scraper).
- 2 teams.
- 1 foreman.

The teams were used to transport the men and the scraper back to the starting point. The laborers were stationed, 2 each, at the valves close by the flushing stations.

The 2 men who watched the progress of the scraper through the pipe could do so by listening to the noise that it made.

Cost of Cleaning Water Pipe, Boston, Mass.—Mr. Dexter Brackett gives the following relative to the cost of scraping pipes in Boston in 1886. Tubercles $\frac{3}{8}$ to $1\frac{1}{4}$ ins. thick were removed. The pipes were not supply mains but distributing pipes, 6 and 12 ins. diameter. Nearly 4 miles of 12-in. pipe were cleaned for 15.6 cts. per lin. ft., and 12 miles of 6-in. pipe for 9 cts. per ft., not including 5 cts. royalty per ft. paid for the use of the scraper. The scraper is a flexible center shaft, $3\frac{1}{2}$ ft. long, composed of coiled steel springs, connecting small castings, to which are hinged two sets of steel scrapers arranged radially around the shaft about 12 ins. apart. These scrapers are held against the sides of the pipe by coiled springs. Back of the scrapers are two rubber pistons, 2 ft. apart, so as to insure water pressure on the machine when passing

branches. No "hatch boxes" were used, as above described, but a section was cut out of the pipe, every 1,000 ft., and the scraper inserted. The section was replaced, clamp sleeves being used, and lead joints poured. The water, at 30 lbs. pressure, forced the scraper through the pipe. In some cases the displaced rust was forced into the service pipes, but this was removed by applying a force pump to the house plumbing and forcing the rust back into the main. In a test of a section of 6-in. pipe that had been laid 38 yrs. the discharge was doubled by the removal of the tubercles or rust.

Cost of Water Pipe Maintenance.*—The diagram, Fig. 12, and Table XII, give some interesting data on the percentage variations in cost of maintenance, labor and cast-iron pipe for the water pipe systems of Chicago, Ill., for the period from 1895 to

Fig. 12.—Cost of Pipe Maintenance.

1906. The data were compiled by the Division of Water Pipe Extension, Mr. W. A. Devering, superintendent.

TABLE XII.

Year.	Total Mileage of Pipe.	Average Cost of Maintenance Per Mile.	Percentage Variation of Average Cost of Maintenance Per Mile.	Cost of Cast-Iron Pipe Per Ton.	Percentage Variation in Cost of Pipe.	Daily Wages of Laborers.
1895.....	1612	\$217.09	100.0	\$26.00	100.0	\$2.14
1896.....	1691	149.23	68.7	23.00	88.4	2.25

*Engineering-Contracting, July 24, 1907.

Cost of Hydrant Maintenance in Winter.*—The accompanying table, abstracted from the report of Metcalf & Eddy, engineers, Boston Finance Commission, shows the cost of hydrant maintenance in Boston, Mass., and in neighboring cities, from the best information available, giving both the estimated total cost and the costs per hydrant. The figure for Boston represents the actual cost as charged upon the books of the department. The costs for the other cities are estimated on the basis of the best information that could be obtained as to methods, wages and duration of work.

Cost of hydrant maintenance in winter in Boston and other New England cities:

City.	No. Hydrants.	Total Cost.	Cost per Hydrant.
Boston, Mass.	7,772	\$19,643	\$2.53
Cambridge, Mass.	1,046	2,498	2.39
Chelsea, Mass.	319	468	1.47
Worcester, Mass.	2,012	2,574	1.28
Lowell, Mass.	1,272	806	.63
Newton, Mass.	976	234	.24

Cost of Thawing Water Pipes by Electricity.†—On the basis of 125 house services thawed by electricity in Rutland, Vt., in February, 1904, the cost of the thawing per service was as follows:

Electricity	\$1.68
Labor	1.85
Teams and drivers.....	0.58
Total	\$4.11

On the average 17 amperes of alternating current at 2,200 volts were required, and at 10 cts. per kw.-hour the current cost was \$1.68, as shown above. The average time consumed was 27 minutes.

Cost of Stop Cock Box Repairs, Etc.‡—From May 13 to December 31, 1907, the Water Department of Cleveland, O., put 9,290 stop boxes to grade, besides replacing 1,803 old boxes with new ones. In addition 330 new stop cock boxes were put in and 10 new stop cock bottoms. The cost of the work was as follows.

		Labor.	Materials.
Boxes put to grade.....	9,290	\$0.409
New boxes put in.....	1,803	0.839	\$1.786
New tops put in.....	330	0.419	0.879
New Bottoms put in.....	10	0.842	0.920
Dug up and cleaned out.....	639	0.839

The wages paid for labor in Cleveland in 1907 were about as follows:

	Per Hour.
Foreman	\$.42
Assistant foreman33
Labor22
Team50

Cost of Subaqueous Pipe Laying.—A line of 12-in. water pipe was laid in a trench dredged across a river 500 ft. wide, as follows:

*Engineering-Contracting, Sept. 22, 1909.

†Engineering-Contracting, March 20, 1907.

‡Engineering-Contracting, Nov. 4, 1908.

The water in the river averaged 4 ft. deep and the trench was dug 6 ft. deep, making a depth of 10 ft. from water surface to bottom of the trench. The small home-made dredge, described in my book on "Earthwork," was used for the dredging. To lower the pipe into the trench A-frame bents were built of 4x8-in. timber, the legs of the bents straddling the trench, and each pipe was supported by an iron rod passing through a hole bored in the horizontal member of the A-frame. These rods were about 12 ft. long, $\frac{1}{2}$ -in. diameter, and threaded their full length. Each rod was provided with a hook at its lower end to hook into an iron ring around the pipe. The pipe was ordinary cast-iron pipe, and was leaded and calked while suspended from the A-frames. Then it was the intention to lower the 500 ft. of pipe all at one time by putting a man with a monkey-wrench at each rod, to give the nut on the rod a turn at a given signal from a whistle. There were 43 bents, 12 ft. apart, and it was decided that a force of 10 men could lower the pipe satisfactorily by giving a few turns of the nuts on 10 rods, then moving to the next 10 rods, and so on. Through carelessness or mischief, some of the men gave more turns to the nuts than the signals called for. This threw the weight of several pipes upon two or more rods, and broke one of them at the hook, which was the weak spot. Immediately all the other rods broke in rapid succession, dropping the pipe line into the river. The pipe settled to the bottom without breaking in two anywhere, and only one joint showed any leakage of air when I inspected the line immediately after the accident. This joint was calked by a man who dived down repeatedly, and struck a few blows each time he was down. However, a diver was sent for to examine every joint, and his inspection showed the pipe line to be intact from end to end. The cost of building the A-frames, placing and calking the pipe line was as follows:

10 men, 3 days, at \$1.75.....	\$ 52.50
1 foreman, 3 days, at \$3.00.....	9.00
10 men, 1 day at work lowering pipe, at \$1.75.....	17.50
1 foreman, 1 day at work lowering pipe, at \$3.00.....	3.00
1 diver, 1 day inspecting line.....	25.00
Traveling expenses of diver.....	15.00
Total for 516 ft. of pipe.....	\$122.00

The above does not include the cost of the iron rods, nor the timber used in the bents, nor the building of a small raft from which to erect the A-frame bents.

From this experience I believe it would be safe to dispense with the threaded iron rods for lowering such a line of pipe. The pipe could be held just above the water surface by small manila ropes, until calked. Then upon cutting one or two of the ropes, the rest would break and allow the pipe to settle into the water. As a 12-in. pipe line is quite buoyant, when filled with air, it settles down gently upon the bottom of the trench. In case a break should occur in the line, threaded rods could be made, and the pipe raised and repairs made at but slightly greater expense than would have been incurred had rods been used in the first place. When pipe

is lowered as above described, one flexible pipe joint is usually provided at each end of the pipe line.

Cost of Laying a Submerged Pipe Across Deal Lake, N. J.*—The following account of the methods and cost of laying 370 ft. of 6-in. cast-iron pipe across Deal Lake, between Interlaken and Loch Arbor, N. J., has been furnished us by Mr. James B. McCord, Civil Engineer, of New York City. The water in the lake at the point of crossing averages 5 ft. deep, and as the bottom is fairly uniform no dredging was necessary. The pipe was laid parallel to a line of old bridge piles and these were used as supports for a temporary platform on which the pipe was laid and connected prepara-

Fig. 13.—Laying Subaqueous Pipe Line.

tory to sinking. The arrangement of the platform is shown in Fig. 13.

In connecting up the pipe six ball joints were inserted at intervals corresponding to changes in profile of the bottom; all other joints were caulked. After the pipe was connected, six light A-frame derricks were set astride the pipe, as shown by the sketch; these derricks were rigged with 6-in. blocks and $\frac{3}{4}$ -in. rope. At intervals between the derricks 2x8-in. braces were nailed to the piles, as shown in the sketch. There were nine of these braces used and each had an iron thimble fastened to the outer end. Ropes tied around the pipe passed through the thimbles and back to the piles around which they were given several turns and fastened. The ropes at the derricks and braces being made taut, the platform was

**Engineering-Contracting*, Feb. 6, 1907.

cut away, leaving the 370 ft. of pipe suspended from the derricks and braces. Two men were then placed at each derrick and brace, who on signal simultaneously lowered away until the pipe rested on the lake bottom. An examination of the pipe after lowering showed that it had suffered no injury. The pipe was standard 6-in. cast-iron pipe weighing $32\frac{1}{2}$ lbs. per lin. ft. The itemized cost of the work exclusive of the cost of the pipe and the ball joints was as follows:

<i>Platform.</i>		
	Per day.	Total.
1 foreman	\$4.00	\$ 4.00
6 laborers	1.75	23.24
Lumber at \$30 per M.....	40.00
Total		\$68.24

<i>Distributing and Connecting Pipe.</i>		
	Per day.	Total.
1 foreman	\$4.00	\$ 4.00
6 laborers	2.00	14.48
Rent of raft.....	25.00
Total		\$43.48

<i>Calking Pipe.</i>		
	Per day.	Total.
1 foreman	\$4.00	\$ 4.00
6 laborers	2.00	28.96
Lead at 6 $\frac{1}{4}$ cts. per lb.....	27.00
Yarn	0.75
Total		\$60.71

<i>Derricks, Braces and Slinging Pipe.</i>		
	Per day.	Total.
1 foreman	\$4.00	\$13.07
4 laborers	2.00	13.06
Rope	9.98
Clevis, bolts, etc.....	6.00
Lumber	22.20
Total		\$64.28

<i>Lowering.</i>		
	Per day.	Total.
20 men	\$2.00	\$32.72

In noting the small cost of the platform it will be observed that the piling was already in place, thus cutting out an expensive item of the work. Summarizing the several items, we have the following:

	Total.	Per lin. ft.
Platform	\$68.24	\$0.1844
Distributing and connecting pipe.....	43.48	0.1175
Calking	60.71	0.1641
Derricks, braces and rigging.....	64.28	0.1737
Lowering	32.72	0.0884
Total for 370 ft.....	\$269.43	\$0.7281

Cost of Laying Pipe Across the Susquehanna.—Mr. James P. Herdic gives the following data relating to laying 10-in. cast-iron pipe across the Susquehanna River, at Montoursville, Pa., a distance of 600 ft., average depth of water being 13 ft. A $\frac{1}{2}$ -in. manilla

rope was first stretched across the river, to act as a ferry line for the scows. The scows were loaded with pipe. The crew of 8 men and foreman were engaged 1 day in this preliminary work, and then laid the 600 ft. of pipe line in the next $2\frac{1}{2}$ days. One ball and socket joint was used to every six ordinary joints. The pipe line was lowered between the two scows, by means of chain pulleys suspended from a heavy sawhorse that spanned the gap between the two boats. The pipe was laid in a gentle curve, bowed up stream, so as to form an arch to resist the stronger currents. This is certainly an excellent record for economic work.

On another place in the Susquehanna River, where the current was so swift that it would swamp a scow if held sidewise in the current by a cable, as above described, the following method was used: A scow was held in the current with its nose up stream, but at an angle with the current; ropes from bow and stern to the nearest shore serving to hold it. In this way the current kept the ropes taut, and the scow remained steady while the lead joints were poured. The pipe line lay across the middle of the scow, which was moved out from under each joint as fast as made. Six common joints to each ball and socket joint were used.

Cost of Laying a Submerged 6-in. Pipe, New Jersey to Ellis Island.—About 5,100 ft. of 6-in. pipe were laid from the New Jersey shore to Ellis Island under 10 to 17 ft. of water. A trench was dug 6 ft. deep by 10 ft. wide in the mud, using a clam-shell bucket. Heavy pipe, weighing 800 lbs. per length, provided with Ward flexible joints, was used. Two scows, each 26 x 80 ft., were fastened together, 6 ft. apart, and provided with two skids of 10 x 10-in. timbers 55 ft. long, leading down between the scows to the bottom of the trench. The skids could be lowered in rough weather. Two lengths of pipe were placed at one time on the skids, a derrick being used for the purpose, and then the scows were warped ahead 24 ft. The whole work occupied just a month, using a force of 10 laborers, 2 calkers and 1 diver to calk any leaks, etc. The best day's work was 516 ft. The line was tested under 80 lbs. pressure, and leaked only 5 cu. ft. in $\frac{1}{4}$ hr.

Cost of Submerged Pipe Laying in Massachusetts.—In a paper entitled "Submerged Pipe Crossings of the Metropolitan Water Board," Journal of the Association of Engineering Societies, 1901, Vol. 27, Mr. C. M. Saville gives in detail the methods of laying submerged pipes and the following cost data, rates of wages and details of cost not being given. The work was done in 1897 in Massachusetts by contract, but the costs are the actual costs to the contractor, plant rental being included.

Mystic River Crossing.—Two lines of 36-in. pipe were laid in a dredged trench, 5 ft. 3 in. c. to c. The trench averaged 8 ft. deep, in mud, and 35 ft. wide on top, and was 1,200 ft. long. A clam-shell dredge was used for most of the work, and averaged 27 lin. ft. of trench, or 260 cu. yds., per day, loading scows, which were dumped half a mile away. After the pipes were laid, the material was reloaded into the scows by the dredge, at the rate of 500 cu.

yds. per day. The cost of excavating the trench was 54 cts. per cu. yd. for the 11,000 cu. yds. The cost of backfilling was 23 cts. per cu. yd.

The river is a tidal stream, with tide fluctuations of 10 ft., and is 8 ft. deep at low water.

A pile foundation was built in the bottom of the trench to lay the pipe on. The piles were driven in bents of 2 piles per bent, bents being 12 ft. apart, and piles 6 ft. apart in each bent. They were driven 23 ft. into the mud, sawed off under water and capped with 10 x 10-in. spruce by a diver. The cost of sawing off and capping was \$2 per pile.

Some of the 36-in. pipes were made with a spherical, or flexible, joint, and weighed 8,260 lbs. per 12½-ft. length, costing \$24 per ton (ordinary pipe cost \$18 a ton), and required 248 lbs. of lead per joint 8 ins. deep. These flexible joints were only used where the pipe line curved vertically.

Six lengths of pipe were joined together on shore, and lowered onto the pile foundation from a scow provided with two derricks. The pipes were slung from the lower chord of a light truss 75 ft. long, to which the derrick tackle was fastened. The scow was 33 x 70 ft., and the pipes were lowered over the side. On the opposite side of the scow was a smaller scow, loaded with gravel, which was fastened to the pipe-laying scow and thus served to counterweight the pipes. There was a 4-in. centrifugal pump on the scow for jetting out the trench if it became filled with mud.

To join the sections of pipe under water (every sixth pipe), a special joint was designed. The spigot end was turned smooth in a lathe to a taper, and had no head. The bell was grooved and designed for a lead joint 5 ins. deep. On shore, a spigot was temporarily inserted in a bell, and the lead joint cast; then the spigot was pulled out, leaving the lead joint in the bell. To re-make this joint under water, a diver guided the spigot to place; near the end of the truss (above referred to) was fastened a hydraulic cylinder, to the piston of which was fastened an iron rod with a hook at the end. A chain having been fastened back of the bell of the last pipe, this hook was fastened into the chain, and, when oil was forced into the hydraulic cylinder, the truss was drawn forward and the spigot forced home into the bell. Fastened to the bell was an iron collar, which guided the spigot into the bell, and also prevented the lead from being displaced by any carelessness on the part of the diver. The pipe line was tested by compressed air, and leaks were caulked by divers.

The total cost to the contractor, including the pipe, which cost \$6.75 per ft., was \$13.25 per lin. ft. of pipe, including the pile foundation and the dredging.

Since the trench averaged 4½ cu. yds. per lin. ft. of pipe, at 77 cts. per cu. yd. for excavation and backfill, the cost of the trench was \$3.45 per lin. ft. of pipe. This leaves \$3.05 per lin. ft. for the remaining items: piling, lead, timber and pipe laying. If the piles were 45 ft. long, there were 7½ ft. of pile per lin. ft. of pipe, which probably cost the contractor about 10 cts. for ma-

terial and 10 cts. for labor (including the \$3 for cutting off), or \$1.50 per lin. ft. of pipe. At 33 lbs. of lead for the ordinary joints, the lead probably cost about 30 cts. per lin. ft. of pipe. The spruce cap on the piles probably cost about \$18 per M, or 10 cts. per lin. ft. of pipe. Hence these three items would total \$1.90 per lin. ft., leaving about \$1.15 per lin. ft. as the cost of laying the pipe. The assumptions and conclusions in this paragraph are mine and not Mr. Saville's.

Cost of Laying a Submerged Pipe at Vancouver, B. C.—Mr. J. Causley gives the following relative to a 12-in. main across the Narrows at Vancouver, B. C., in 1906:

There have been seven 12-in. mains placed across the Narrows at various times during the past 19 years. The last one has just been put in position, and of the method of accomplishing this the writer purposes giving a short description, trusting that it may prove of some interest, for the reason that it differed from the method usually followed (with variations to suit particular cases) in such work, viz., that of building a staging, or anchoring a string of rafts along the line to be followed, slinging the pipes over the position they are intended to occupy, jointing them up and lowering the connected line into place.

This method would not have been suitable in the cases under consideration on account of the water varying from 66 ft. deep at low tide to 75 ft. deep at ordinary high tide. The tide is very strong, running at speeds up to 8 knots per hour; also, and perhaps the most important of all, nearly the whole of the shipping trade of Vancouver, including ocean passenger and freight steamers, from 8,000 tons downwards, sailing ships towed in and out by tugs, coast steamers, rafts, coal barges, transfers towed by tugs, etc., passes through these Narrows. A system of hauling the pipes across was first put into practice by the Water Works Company, this system being greatly improved by the late City Engineer, Colonel Tracy, M. Can. Soc. C. E., and the Water Works staff.

About three years ago it was intended to place another main across the Narrows, and in the early part of 1904 a contract was made with Messrs. Robertson, Godson & Co., of Toronto and Vancouver, for the supply of cast-iron pipes for a submerged main, in accordance with the following specifications:

To be 12 ins. in diameter internally, 1 in. in thickness, lengths to lay 12 ft. each, of the best cast iron, strong, tough gray metal, cast vertically with the hub end down, the bell end to be bored spherically, and the spigot end to be turned where it fits in contact with the bored surface. To be tested to a pressure of 500 lbs. per sq. in. and hammered under pressure. To be coated with Dr. Angus Smith's preparation, or preferably with Warts, Dove & Co.'s bitulithic solution.

The pipes were obtained from Stavely, near Glasgow, in Scotland, and weighed between 1,725 and 1,800 lbs. each.

**Engineering-Contracting*, April 22, 1908.

The half section, Fig. 14, at a flexible joint shows the latest form of the bell and spigot of a pipe. The shape of the bell has been altered from that of the earlier forms to cause the pipes to offer as little resistance as possible in sliding along the bed of the Inlet.

The pipes were delivered at Vancouver in August, 1905, but it was not convenient to place them in position till the latter part of 1906, when it was decided that they should be laid directly by the city, under the superintendence of Mr. S. Maddison, the manager

—A

Eng. Contr.

Fig. 14.—Flexible Joint.

of the water works, who had had much experience in the work of laying previous mains. Captain Westcott, who was contractor for laying two of the previous mains, and foreman on laying the steel main, was engaged as foreman of the work. This main was to take the place of No. 3 pipe line, the pipes of which were taken apart by a diver and brought to the bank.

A chute, Fig. 15, was constructed of 14-in. x 2-in. dressed plank, with 4-in. x 1-in. battens on each side—i. e., projecting 2 ins. above the plank—supported at every 6 ft. by cross pieces of 3-in. x 4-in.

Fig. 15.—Chute.

quartering, each on 2 posts of 3 in. x 4 in., from low water on the north side of the Narrows extending back the length of the main. Each length of pipe was tested separately under a pressure of 350 lbs. to the square inch. The pipes were then placed on the chute spigot ends to the south, with a piece of 14-in. x 2-in. plank, about 2 ft. long, on the bed of the chute running between the side battens under each pipe at the bell end. The piece of plank was notched out at the top side and upper end, so as to go under support, and steady the bell, and keep the pipe in the center of the chute. The

under skids of these blocks were well greased. The spigot of each pipe was pressed home in the bell of the next one, lead run in and calked to make a tight joint. No gaskets were used, as the bells and spigots were bored and turned to make tight and flexible joints. Each joint required from 60 to 70 lbs. of lead, making about $3\frac{1}{2}$ tons of lead used in all. The pipes, after being put together and jointed, were tested collectively under a pressure of 150 lbs. per square inch.

A line was pushed through the pipes with a rod made of a number of long slats of wood nailed together and a $1\frac{3}{4}$ -in. steel wire cable hauled through them.

Over the lower or south end of the string of pipes a cast-iron cap 1 in. thick, with strengthening ridges on the outer side, and flange overlapping the end of the pipe, was placed, leaded and calked. This cap had a 2-in. circular hole in the center with a stuffing-box. Through this was passed a 2-in. turned rod 3 ft. 6 ins.

Fig. 16.—Arrangement of Hauling Cables.

long, and the hemp packing was well tightened up around it. On the inner end of the rod was an eye through which the end of the $1\frac{3}{4}$ -in. steel wire cable, which went through the line of pipes, was passed, doubled back on the cable, and secured with four clips. The outer end of the eye-bar, on which a screw thread was cut, went through a stirrup-shaped ring and was made fast to it with two nuts. To this stirrup one of the hauling cables was attached and secured in the same manner as the cable inside the pipes was secured to the other end of the bar. By these means the cable had no tension on the front end of the string of pipes.

The end length of pipe carrying the cap, etc., was covered with a wooden lagging, bound at three places with $\frac{3}{8}$ -in. wire rope. Figure 16 readily explains the arrangements made.

The cable on the west side of the pipes was attached to the 40th pipe by taking two turns round the pipe, bringing the end back to the cable, and fastening it with 4 clips. The cable on the east side of the pipes was secured to the 18th pipe by means of a chain, which had a round turn round the pipe, and the ends made fast

to the cable with clips. Iron bands were put round the pipe and cables fastened at intervals to enable a fair pull to be taken.

On the upper, or north end of the pipe a cap similar to the one at the south end was placed, with the exception that the 2-in. circular hole in the center was through a plain boss. A 2-in. round bar passed through this hole. The inner end of this bar had an eye to which the cable through the pipes was attached in the same way as the other end of the cable was fastened to the bar through the cap at the south end of the pipes. On the outer end of this bar a screw thread was cut, and the cable through the pipes was tightened up with a nut. A second was placed above the first one for the sake of security. A length of 12-in. pipe, 4 ft. long, was fitted into the bell of the last pipe for the flange of the cap to fit on to. The whole was leaded and thoroughly calked. This was completed on Aug. 19.

It had taken about a month to do this work, with a gang of about seven men, under the superintendence of Captain Westcott. There were 109 pipes, making 1,308 ft. of pipes, whose weight

Fig. 17.—Arrangement of Gripper.

varied from 1,725 lbs. to 1,800 lbs. each, giving a total weight of about 96.05 tons. Including lead caps, internal cable, etc., the total weight would be about 102½ tons.

1,800 ft., 1½ ins. diameter, and 1,800 ft., 1¼ ins. diameter, fresh steel-wire cables had been bought. These cables were not new, but had been used for hoisting in the mines. Also four new 6-in. (circumference) 120 fathom manila ropes had been purchased at \$160.00 each, for tackle. Six new 3-sheave blocks and two new single-sheave blocks had been made in the water works shops. The cables, on their reels, had been taken across to the north shore of the Narrows.

The end of a line was taken across, attached to the end of one of the cables, and the cable was hauled across, a snatch block and four horses being used. No power tackle was used, as the hauling had to be done in the space of about 15 minutes at slack water.

One cable was hauled across at slack water on Aug. 15, one on the 18th, and one on the 19th. By Aug. 23 everything was ready to begin hauling. The cables had been examined by the diver and tightened up with their blocks and tackles.

By means of a gripper, Fig. 17, to each of two of the cables was attached a tackle consisting of a pair of 3-sheave blocks with one

of the 120-fathom 6-in. manilla ropes rove through them worked by a capstan to each tackle driven by one or two horses. The other cable had two tackles, with a pair of 3-sheave blocks attached to each tackle, each tackle worked by a capstan. See Fig. 18. The drum of the capstan, Fig. 19, was 18 ins. in diameter, and the lever arms 11 ft. each. The cable, however, with the two tackles attached, had been left taut too long; the flood tide caught it and carried it up channel about 100 ft. at the center, drawing two lengths of pipe slightly out of line before it could be loosened. It was necessary to draw it back to the north side and haul it across afresh. This had been done by Aug. 25, and everything found to be in order. Passing vessels had caused some inconvenience when getting the lines across.

Monday, August 27.—Hauling began at mid-day at low water with four horses, i. e., one at each capstan, and was also continued on the slack water in the evening, lasting altogether about

Fig. 18.—Arrangement of Capstans.

five hours, and moving the main about 178 ft. The work could not be carried on longer as the tide when stronger would have caught the cables and carried them out of line. After the first hauling the manager went down in diving dress, examined the pipes that had moved, found that they had been drawn straight, and that the joints were uninjured.

Tuesday, August 28.—Hauling was carried on from noon to 2 p. m., and from 5 to 8 p. m. The main was hauled 194 ft.; in all, 372 ft. Four horses had been used, i. e., one at each capstan.

Wednesday, August 29.—Up to 7 p. m., only about 35 ft. had been hauled. The horses had been doubled on two capstans and had not pulled well together; the tide also had not served well. Hauling was carried on from 7:10 to 7:30 p. m., when it was stopped by a signal from the other side (the light put out). It was found that one side of the chute had sunk where swampy ground was crossed, and that the pipes were slipping off. About 87 ft. had been hauled; in all 450 ft.

Thursday, August 30.—The chute was strengthened early in the

day. In the morning the tide was not favorable for hauling, which was not begun till about 6 30 p. m. Only one capstan was doubled till about 9:30 p. m., when a second horse was put on No. 1 capstan. Hauling was stopped about 1 a. m., as the horses were unable to work longer. About 300 ft. had been hauled; in all 750 ft.

Friday, August 31.—In the morning the pipe was examined by the diver, who went right along the part under water from end to end, and found everything in good order. There is a soft shingle bank extending from the north side to within about five hundred feet from the south side of the Narrows, and the pipes had

Fig. 19.—Plan and Elevation of Capstan.

ploughed into this for a depth of about two feet and moved boulders that were in their way. Further south the bottom is a sandy hardpan.

Hauling began about 5 p. m., and one fleet (the length of travel of the moving blocks, about 75 ft.) was hauled by about 7 p. m. The tackles were then overhauled. Hauling was continued again from about 8 to 8:20 p. m., when the gripper on the eastern cable gave way. It was got in order again and operations were continued. About 12:30 a. m., the central cable slipped in the gripper and work was suspended for the night. About 150 ft. hauled; in all 900 ft.

The pull was now becoming heavier.

Saturday, September 1.—The diver went down in the morning and found everything in good shape.

Hauling began about 4:30 p. m. The pipe would not start at once, and the gripper on the central cable (No. 1 capstan) slipped at about 4:45 p. m. It had to be loosened and a fresh grip taken, when the pipe was started. The fleet was finished at 6:15 p. m. It was found from measurement that 162 ft. still required to be hauled. The tackles were overhauled; a sheave in one of the blocks, which was found to be cutting (the hole had become enlarged about $\frac{1}{4}$ in.) was replaced by another, and hauling was begun again about 7:45 p. m. About 9 p. m. it was found that the head of No. 2 capstan was giving way, and work had to be suspended till a new drum could be made, 169 ft. were hauled; in all 1,069 ft.; 155 ft. remained to be hauled.

Monday, September 3.—A new capstan barrel had been made and placed in position, and hauling was begun at 8:15 a. m. The main was moved about 40 ft., but the tide was found to be running out too strongly, and work was stopped. The pull had become very heavy, as so much of the main was on the ground and part of it was coming up hill. Six horses were used this day, viz., two each on Nos. 1 and 2 capstans, and one each on Nos. 3 and 4.

Hauling was begun again at 11:10 a. m. A gripper slipped soon after starting. A fresh pin was put in and tightened up, and hauling was continued. Before long the rope of the tackle of No. 2 capstan got under the barrel of the capstan and had to be cleared. The fleet was finished at 12:25 p. m. Seventy feet still required to be hauled.

The tackle was overhauled and work begun again at 1 p. m. The rope got under the barrel of No. 2 capstan again and had to be cleared. The hauling was heavy, but the pipe moved steadily. The work was finished at 2:45 p. m., the front end of the pipe being above low water. Total distance hauled, 1,224 ft.

The main was tested on September 5, under a pressure of 125 lbs. per sq. in., and found to be perfectly tight.

Captain Westcott employed 11 men during hauling, as well as the diver and the drivers of the teams.

The cost of the 1,398 lin. ft. of submerged pipe in place was as follows:

Materials.

965.05 tons 12-in. pipe at wharf.....	\$3,842.00
Removing to site of work.....	200.00
Lead, 7,000 lbs.....	491.98
8,040 ft. B. M. lumber for chute, at \$18.....	144.72
2,436 ft. B. M. lumber for platform, at \$17.....	41.41
3 kegs nails, at \$4.....	12.00

Labor.

Building chutes and platform, putting up capstans, placing and jointing pipe, July 2 to Aug. 11.....	1,002.69
Hauling pipe across the narrows (Aug. 25 to Sept. 8)....	1,163.23

Miscellaneous.

Materials, provisions, cartage, incidentals, etc..... 470.00

Total\$7,367.98

Plant purchased fresh 920.00

Grand total, 1,308 ft., at \$6.35.....\$8,297.98

The above \$930 worth of plant purchased for this work consisted of the following items:

2,000 ft. $\frac{5}{8}$ -in. new steel cable, at 7 cts..... \$140.00

2,800 ft. $1\frac{1}{4}$ -in. and $1\frac{3}{4}$ -in. old steel cable..... 150.00

2,880 ft. 6-in. (circumference) Manila rope..... 640.00

Total \$930.00

This does not include the blocks.

The wages paid were high, being 25 to 30 cts. per hr. A team and driver received \$8 per day; diver, \$15 per day. Of the \$1,163 item of hauling the pipe across the Narrows, \$328 was for team and driver time.

The foregoing costs do not include the cost of taking up and removing the old pipe line, which was as follows:

Labor\$1,652.77

Materials and general expense..... 403.59

Total\$2,056.36

Cost of Laying Pipe Across the Willamette River.—A 32-in. pipe across the Willamette River, Oregon, was laid in 1895. Two scows and an inclined cradle were used. The gang was 16 men and 1 diver, and they laid 80 ft. of pipe per day in a trench 23 ft. below the water surface. The plant and methods are described in the *Trans. Am. Soc. C. E.*, Vol. 33, p. 257.

Cost of a Wood Stave Pipe Line at Denver.—Mr. James D. Schuyler, in *Trans. Am. Soc. C. E.*, Vol. 31 (1894), describes and illustrates very fully the building of a wooden pipe line for Denver, Colo. The pipe was 30 ins. diameter, made of staves of Texas pine $1\frac{1}{4}$ ins. thick, with $\frac{1}{2}$ -in. round iron bands. A pipe laying gang consisted of 8 to 16 men according to the number of bands per unit of length, half the gang being employed in back clinching. On a 34-in. pipe a gang placed 700 to 1,000 bands per day, laying from 150 to 300 lin. ft. of pipe. On a 44-in. pipe the rate was 500 bands per day. The cost of erection was from 5 cts. per band on a 30-in. pipe to 10 cts. per band on a 48-in. pipe. The cost of 16.4 miles of 30-in. pipe was \$1.38 per ft., distributed as follows:

1,869 M Texas pine, at \$27.50.....\$ 51,359

271,900 steel bands ($\frac{1}{2}$ -in.) and shoes..... 54,300

Erection of pipe, 5.1 cts. per band, by contract..... 13,866

\$119,565

In addition the trenching and backfilling cost 48 cts. per ft., which was unusually expensive.

Cost of Wood Stave Pipe, Astoria, Oregon.—Mr. John Birkinbine gives the following:

An 18-in. wooden stove pipe at Astoria, Oregon, $7\frac{1}{2}$ miles long, cost \$0.90 per ft., in place including appurtenances, with lumber

at \$35 per M and steel bands at 4.8 cts. per lb. Mr. A. L. Adams gave the details as follows: Including all appurtenances the cost was 90 cts. per ft., but it was 76 cts. excluding appurtenances. The labor cost as follows:

Building and spacing bands.....	55%
Back-cinching	26
Repainting iron bands.....	3
Backfilling to depth of 6 ins. over pipe....	8.75
Placing specials	3.50
Placing air valves.....	0.75
Unclassified labor	3.00
Total	100.00

In Colorado, $5\frac{1}{2}$ miles of 28-in. wooden stove pipe, under a head starting at 20 ft. and ending at 150 ft., cost \$1.67 per ft., exclusive of ditching. The cost of $6\frac{1}{2}$ miles of 36-in. to 44-in. pipe was \$2.60 per ft. exclusive of ditching. The cost of $6\frac{1}{2}$ miles of 36-in. to 44-in. pipe was \$2.60 per ft. exclusive of ditching. In 1903 nearly 2 miles of 42-in. wooden stove pipe was laid at Absecon, N. J., for Atlantic City, at \$2.25 per ft. in place. It was laid on the hydraulic grade line, requiring no heavy banding.

Estimated Cost of Wood Stave Pipe.—In 1898 Mr. A. L. Adams made the following estimates of cost per foot of wood stave pipe in Chicago, exclusive of contractors' profits. The cost includes laying the pipe, but does not include hauling. Unfortunately the details, upon which the estimate is based, are not given. Apparently the costs do not include trenching.

Diam., ins.	25-ft. head.	50-ft. head.	100-ft. head.	200-ft. head.
12	\$0.42	\$0.49	\$0.63	\$0.85
18	0.60	0.80	1.02	1.46
24	0.79	0.91	1.14	1.61
30	0.96	1.12	1.44	2.06
36	1.19	1.40	1.82	2.65
42	1.40	1.68	2.23	3.33
48	1.55	1.85	2.46	3.67
54	2.23	2.62	3.43	5.02
60	2.85	3.35	4.37	6.40
66	3.21	3.81	5.00	7.38
72	3.65	4.38	5.83	8.73

Cost of Wood Stave Pipe Line at Atlantic City.—Mr. Kenneth Allen and Mr. C. J. Myers give the following data relative to a wood stave pipe built by contract for Atlantic City, N. J., in 1904.

The pipe is 42 ins. diameter, of Washington fir, the staves being cut from 2 x 6-in. lumber, and measuring $19/16$ ins. thick. The bands are spaced 12 ins. apart, and are of $\frac{1}{2}$ in. round steel. The bands were bent by winding them around a cylinder 38 ins. in diameter. After bending they were wired together in bunches of five, and dipped in hot (400° F.) Mineral Rubber Field Paint for about 3 mins. About 750 bands were bent and dipped per day by a gang of 7 men and a foreman, using 20 gals. of mineral rubber.

Trenching was begun Feb. 4, and the 9,800 ft. of pipe was completed Apr. 16. The material was largely sand. The pipe was

laid in the bed of an old canal, sections of which were dammed off and pumped out with two 3-in. gasoline pumps.

The pipe gang was as follows:

- 1 foreman.
- 2 men handling material.
- 2 men driving staves.
- 2 men tightening bands.
- 1 man rounding out pipe by hammering inside.
- 2 men back-cinching.
- 1 boy painting bands.
- 2 men tamping.

There were also:

- 2 day men on gasoline pumps.
- 2 night men on gasoline pumps.
- 2 men on diaphragm pumps.
- 35 men backfilling.

The first 26% of the work cost considerably more than the last 74%, due to the colder weather that prevailed in February.

The labor cost of the first 26% done during Feb. 4 to Mar. 5, was as follows, per lin. ft.:

Excavation and Backfill:	
4.92 hrs. labor at 15 cts.....	\$0.74
0.28 hrs. foreman at 40 cts.....	0.11
Making Pipe:	
1.05 hrs. labor at 20 cts.....	\$0.21
0.13 hrs. labor at 40 cts.....	0.05

During Mar. 5 to Apr. 16, the labor cost was as follows per lin. ft.:

Excavation and Backfill:	
4.91 hrs. labor at 15 cts.....	\$0.74
0.18 hrs. foreman at 40 cts.....	0.07
Making Pipe:	
0.73 hrs. labor at 20 cts.....	\$0.15
0.07 hrs. foreman at 40 cts.....	0.03

During the first period there was less excavation per lin. ft. and less water to handle.

The freight on the staves from Washington was \$300 per car. The contract price for the 42-in. pipe was \$2.25 per lin. ft. exclusive of earthwork.

Labor on a Wooden Stave Pipe at Ogden.—Mr. Henry Goldmark gives the following relative to 6 ft. wood stave pipe line, 27,000 ft. long, built in 1896 near Ogden, Utah. The pipe is laid in a trench 8½ ft. wide and 9½ ft. deep. The maximum hydrostatic pressure is 50 lbs. per sq. in. The lumber was Douglas fir, the staves measuring 2½ x 8 ins. before final dressing, and 2 x 7½ ins. dressed. Sills, 6 x 8 in. x 8 ft., were laid 8 ft. apart, with 6 x 6-in. chocks or cradles on top. The bands were ¾ to 1 in., and there were two shoes to each band. A gang of 20 men built about 70 lin. ft. per day; 10 of these men assembled the pipe and put on enough bands to hold the staves together; the other 10 men put on the remaining bands and did the back-cinching. There were 1,500,000 ft.

B. M. of lumber and 2,500,000 lbs. of steel in bands and shoes of this 27,000 lin. ft. pipe line.

Labor on a Wooden Stave Pipe at Lynchburg.—A wood stave pipe line was laid in 1906 at Lynchburg, Va. The pipe is 30 ins. diam., made of 2 x 6-in. redwood staves, banded with $\frac{1}{2}$ -in. steel rods. The cast shoes weigh 1 lb. each; 820,000 bands were used for 2,000,000 ft. B. M. of staves. A gang of 18 men averaged 130 ft. of pipe built per day; 12 of these men fit up and assemble the pipe, and 6 men back clinch. The trench was 6 ft. wide, the upper part being excavated with drag scrapers.

Cost of a Reinforced Concrete Conduit.—To Mr. G. C. Woollard, engineer for James Stewart & Co., contractors, I am indebted for the following data relating to the construction of a 5-ft. concrete-steel conduit in the Cedar Grove Reservoir, near Newark, N. J. Two conduits, side by side, were built across the bottom of the reservoir from the gate house to a tunnel outlet. Since the conduits are to be submerged, a small amount of leakage at end joints is not objectionable.

Trial sections of the conduits were tested under hydrostatic pressure; one of the conduits broke under an internal pressure of 15 lbs. per sq. in., rupture taking place at a joint near the springing line of the arch where work had been stopped over night during construction. Another section, in which no stopping had occurred, resisted a pressure of 34 lbs. per sq. in.; but the leakage of the wooden bulkhead used in the test prevented applying a greater pressure.

The concrete was 1 : 2 : 5, no stone exceeding $1\frac{1}{2}$ ins. being used. Expanded metal, No. 10 steel with a 3-in. mesh, weighing 0.56 lbs. per sq. ft., made by the Associated Expanded Metal Companies, was used. When construction was begun the sheets of expanded metal were bent up into the middle wall, but it was found that the inclined part of the metal acted as a screen to separate the mortar from the stone. Hence the form of the metal was made as in Fig. 20.

"The particular thing that was insisted upon by both Mr. M. R. Sherrerd, the chief engineer of the Newark Water Department, and Mr. Carlton E. Davis, the resident engineer at Cedar Grove Reservoir, in connection with these conduits, was that they be built without sections in their circumference, that the whole of the circumference of any one section of the length should be constructed at one time. They were perfectly willing to allow us to build the conduit in any length section we desired, so long as we left an expansion joint occasionally which did not leak.

"The good construction of these conduits was demonstrated later, when the section stood 40 lbs. pressure to the square inch, and, in addition, I may say that these conduits have not leaked at all since their construction. This shows the wisdom of building the conduit all around in one piece, that is, in placing the concrete over the centers all at one time, instead of building a portion of it, and then

completing that portion later, after the lower portion had had an opportunity to set.

"The centers which I designed on this work were very simple and inexpensive, as will be gathered from the cost of the work, when I state that this conduit, which measured only 0.8 cu. yd. of concrete to the lineal foot of single conduit, cost only \$6.14 per cu. yd., built with Atlas cement, including all labor and forms and material, and expanded metal. The forms were built in 16 ft. lengths, each 16 ft. length having five of the segmental ribbed centers such as are shown in Fig. 20, viz., one center at each end and three intermediate centers in the length of 16 ft. These segments were made by a mill in Newark and cost 20 cts. apiece, not includ-

Fig. 20—Centers for Concrete Conduit.

ing the bolts. We placed the lagging on these forms at the reservoir, and it was made of ordinary 2 x 4 material, surfaced on both sides, with the edges bevelled to the radius of the circle. These pieces of 2 x 4 were nailed with two 10d. nails to each segment. The segments were held together by four $\frac{3}{4}$ -in. bolts, which passed through the center, and 1 $\frac{1}{2}$ -in. wooden tie block. There was no bottom segment to the circle. This was left open, and the whole form held apart by a piece, B, of 3 x 2 spruce, with a bolt at each end bolted to the lower segment on each side.

"The outside forms consisted of four steel angles to each 16 ft. of the conduit, one on each end, and two, back to back, in the middle of each 16 ft. length. These angles were 2 x 3, with the 3-in.

side on the conduit, and the 2-in. side of the angle had small lugs bolted on it at intervals, to receive the 2 x 12 plank, which was slipped down on the outside of the conduit, as it was raised in height. The angles were held from kicking out at the bottom by stakes driven into the ground, and held together at the top by a ½-in. tie-rod.

"The conduit was 10 ins. thick, save at the bottom, where it was 12 ins. The reason for the 12 ins. at the bottom was that the forms had to have a firm foundation to rest on, in order to put all the weight required by the conduit on them in one day or at one time, without settling. We therefore excavated the conduit to grade the entire length, and deposited a 4-in. layer of concrete to level and grade over the entire length of the conduit line. This gave us a good, firm foundation, true and accurate to work from, and this is the secret of the good work which was done on these conduits. If you examine them, you will say that they are one of the neatest jobs of concrete in this line that has been built, especially with regard to the inside, which is true, level and absolutely smooth. [The author can confirm this statement.] When the conduit is filled with water, it falls off with absolutely no point where water stands in the conduit owing to its being out or the proper amount of concrete not being deposited.

"The centers were placed in their entirety on a new length of conduit to be built, resting upon four piles of brick, two at each end as shown. The first concrete was placed in the forms at the point marked X and the next concrete was dropped in through a trap door cut in the roof of the conduit form at the point marked Y. This material was dropped in to form the invert, and this portion was shaped by hand with trowels and screened to the exact radius of the conduit. The concrete was then placed continuously up the sides, and boards were dropped in the angles which I have mentioned, and which served as outside form holders till the limit was reached at the top, where it was impossible to get the concrete in under the planking and thoroughly tamped. At this point the top was formed by hand and with screeds.

"Each 16-ft. length of this concrete was made with opposite ends male and female respectively, that is, we had a small form which allowed the concrete to step down at one end to 3 ins. in thickness for 8 ins. back from the end of the section, and on the other end of the section it allowed it to step down to 3 ins. in thickness in exactly the opposite way, making a scarf joint. This was not done at every 16 ft. length, unless only 16 ft. were placed in one day. We usually placed 48 ft. a day at one end of the conduit with one gang of men. This was allowed to set 24 hours, and, whatever length of conduit was undertaken in a day, was absolutely completed, rain or shine, and the gang next day resumed operations at the other end of the conduit on another 48 ft. length. This was completed, no matter what the weather conditions were, and, towards the close of this day the forms placed on the preceding day were being drawn and moved ahead.

"The method used in moving these forms ahead for another day's work is probably one of the secrets of the low cost of this work, and it is one which we have never seen employed before. The bolt at A, Fig. 20, was taken out, and the tie brace B thrown up. We had hooks at the points C. A turnbuckle was thrown in, catching these hooks, and given several sharp turns, causing the entire form to spring downward and inwards, which gave it just enough clearance to be carried forward, without doing any more striking of forms than pulling the bolt at A. This method of pulling the forms worked absolutely satisfactorily, and never gave any trouble, and we were able to move the forms very late in the day and get them all set for next day's work, giving all the concrete practically 24 hours' set, as we always started concreting in the morning at the furthest end of the form set up and at the greatest distance from the old concrete possible in the 48 ft. length, as the furthest form had, of course, to be moved first, it being impossible to pass one form through the other.

"Six 16-ft. sections of these forms were built, and three were used each day on each end, as shown by the diagram MN, Fig. 20, which gives the day of the month for the completion of each of seven 48-ft. sections.

"A gang of men simply shifted on alternate days from end to end of the conduit, although several sections were in progress at one time; and of course, finally, when a junction was made between any division, say of 1,000 ft., to another 1,000 ft., one small form was left in at this junction inside of the conduit, and had to be taken down and taken out the entire length of the conduit.

"The centers for a 16-ft. length of this conduit cost complete for labor and material, \$18.30, but they were used over and over again; and, after this conduit was completed, they were taken away for use at other points, so that the cost is hardly appreciable, and the only charge to centers that we made after the first cost of building the centers, was on account of moving them daily. Part of this conduit was built double (two 8-ft. conduits) and part single, the only difference being that, where the double conduit was built, two forms were placed side by side, and not so much was undertaken in one day.

"These conduits, when completed and dried out, rung exactly like a 60-in. cast-iron pipe, when any one walked through them or stamped on the bottom."

Mr. Woollard gives the following analysis of the cost per cubic yard of the concrete-steel conduit above described:

	Per cu. yd.
13 bbl. cement	\$1.43
10 cu. ft. sand.....	0.35
25 cu. ft. stone.....	1.10
26 sq. ft. expanded metal at 3 cts.	0.78
Loading and hauling materials 2,000 ft. to the mixing board (team at \$4.50)	0.50
Labor mixing, placing, and ramming ..	1.38
Labor moving forms.....	0.60
Total	\$6.14

Wages were 17½ cts. per hr. for laborers and 50 cts. per hr. for foremen. The concrete was 1 : 2 : 5, a barrel being assumed to be 3.8 cu. ft. The concrete was mixed by hand on platforms alongside the conduit. The cost of placing and ramming was high, on account of the expanded metal, the small space in which to tamp, and to the screeding cost. When forms were moved they were scraped and brushed with soft soap before being used again.

From Mr. Morris R. Sherrard, Engr. and Supt. Dept. of Water, Newark, N. J., I have received the following data which differ slightly from those given by Mr. Woollard. The differences may be explained by the fact that the cost records were made at different times. Mr. Sherrard states (Sept. 26, 1904) that each batch contains 4 cu. ft. of cement, 8 cu. ft. of sand, and 20 cu. ft. of stone, making 22 cu. ft. of concrete in place. One bag of cement is assumed to hold 1 cu. ft. He adds that a 10-hr. day's work for a gang is 63 lin. ft. of single 5-ft. conduit containing 474 cu. yds. of concrete and 1,260 sq. ft. of expanded metal. This is equivalent to ¾ cu. yd. of concrete per lin. ft. The total cost of material for one complete set of forms 64 ft. long was \$160; and there were 7 of these sets required to keep two gangs of men busy, each gang building 63 lin. ft. of conduit a day. Since the total length of the conduit was 3,850 ft., the first cost of the material in the forms was 18 cts. per lin. ft.

Cost of Labor on 5-ft. Conduit:

	Per day.	Per cu. yd.
1 foreman on concrete	\$ 3.35	\$0.07
1 water boy	0.75	0.01
11 men mixing at \$1.75	19.25	0.39
5 men mixing at \$1.50	7.50	0.16
4 men loading stone at \$1.40	5.60	0.12
4 men wheeling stone at \$1.40	5.60	0.12
2 men loading sand at \$1.40	2.80	0.06
2 men wheeling sand at \$1.40	2.80	0.06
1 man placing concrete at \$1.75	1.75	0.04
6 men placing concrete at \$1.50	9.00	0.19
2 men supplying water at \$1.50	3.00	0.06
1 man placing expanded metal at \$2	2.00	0.04
1 man placing expanded metal at \$1.50	1.50	0.03

Total labor on concrete\$64.90 \$1.35

Cost of Labor Moving Forms.

	Per day.	Per cu. yd.
4 carpenters placing forms	\$13.00	\$0.27
2 helpers placing forms	4.00	0.08
1 carpenter putting up boards for outside forms	2.75	0.06
1 helper putting up boards for outside forms	2.25	0.05
2 helpers putting up boards for outside forms	3.50	0.07
1 team hauling lumber	4.50	0.09
1 helper hauling lumber	1.75	0.04

Total labor moving forms.....\$31.75 \$0.66

It will be noted that it required two men to bend and place the 700 lbs., or 1,260 sq. ft., of expanded metal required for 63 lin. ft. of conduit per day, which is equivalent to 0.5 ct. per lb., or 0.3 ct. per sq. ft., for the labor of shaping, placing and fastening the metal.

Reference to Other Concrete Conduits.—In the section on Sewers

will be found more data on reinforced concrete conduits. See also Gillette and Hill's "Concrete Construction—Methods and Cost."

Cost of Brick Conduit.—A conduit of horseshoe shape, 7½ ft. in diameter, was built with a brick arch 8 ins. thick and a concrete invert lined with brick 4 ins. thick. The following relates to the brickwork. Work was done by contract, in 1884, in Massachusetts. Mr. Henry A. Carter gives the cost of 960 M of brickwork was as follows:

Labor:	
Foreman, 39 days, at \$5.00.....	\$ 195.00
Laborers, 320 days, at \$1.35.....	400.00
Laborers, 1,752 days, at \$1.50.....	2,628.00
Masons, 753 days, at \$4.90.....	3,601.50
Carpenters, 4 days, at \$2.50.....	10.00
Horse and car, 90 days, at \$3.15.....	283.50
Miscellaneous labor	23.75
Materials:	
Brick, 960,000, at \$8.40 per M.....	9,024.00
Cement, 316 bbls. Portland, at \$3.20.....	1,008.00
Cement, 1,681 bbls. natural, at \$1.26.....	2,118.06
Sand, 571 cu. yds., at \$1.20.....	685.20
Plant:	
Boiler, 15 days, at \$1.00.....	15.00
Pumps, 101 days, at \$0.25.....	25.25
Cars and tools	79.00
Forms and centers	304.00
Coal, 12 tons, at \$6.00.....	72.00
Office building	57.00
Total	\$20,529.26
General expense, timekeeper, watchman, etc.	1,038.36
Grand total	\$21,567.62

These 960 M of brick made 1,600 cu. yds. of masonry, or 570 bricks per cu. yd. About 5% were culled and rejected. It took 123 bbls. of cement per cu. yd. Masons each averaged 1,250 bricks per day, which was a poor average for men paid such high wages. The cost per cubic yard of this brick masonry was,

	Per cu. yd.
Masons laying, at 49 cts. per hr.....	\$ 2.38
Laborers tending, including unloading, etc., 15 cts. per hr.	2.07
Brick, 570 at \$8.40 per M.....	5.59
Sand, 0.35 cu. yd., at \$1.20.....	0.42
Cement, 1.23 bbls.	1.55
Forms	0.19
General expense and miscellaneous	1.05
Total per cu. yd.	\$13.25

The cost of 2,500 cu. yds. of concrete in the foundation and invert was as follows:

	Per cu. yd.
Labor:	
Foreman, at \$2.75.....	\$0.16
Laborers, 20 at \$1.65.....	1.22
Carpenters, 2 at \$2.25.....	0.15
Horse and car, at \$3.15	0.15
Miscellaneous labor	0.01
Total labor	\$1.69

Materials for concrete	\$3.34
Lumber for forms	0.06
Cement shed	0.04
Tools, pumping, etc.	0.09

Grand total\$5.21

Weight of Iron or Steel Stand Pipes.—With iron or steel assumed to have a safe tensile stress of 12,500 lbs. per sq. in., assuming that single riveted joints have 66% of the strength of the solid sheet and that double riveted joints have 75%, each sheet to build 5 ft. Table XIII was calculated by Mr. A. H. Howland in 1886.

TABLE XIII

Diam. ft.	standpipe, ft.	Gallons per ft. of depth.	Minimum thick- ness for top, in.	Distance from top to carry min- imum thick- ness, ft.	Distance from top to carry single rivets, ft.	Constant to add to minimum thick- ness for each 5 ft. below dist. given in 4th col., in.

50		14,688.0	0.3465	25	10	0.0693

From this table the details of any iron stand pipe can be determined and tabulated. Then from such a tabulation calculate the weight of the metal as follows: Figure the superficial area of the stand pipe of given diameter for a ring 5 ft. in height, multiply this by the weight of a square foot of metal of the thickness of each ring, add them all together and add the weight of the bottom, and then add 10% for laps and rivets.

Cost of a Standpipe, Quincy, Mass.—Mr. C. M. Saville gives the following relative to a 300,000 gal. steel standpipe built in 1900, at Quincy, Mass. The pipe is 30 ft. diam. and 64 ft. high. The lowest plates are 9/16 in. thick, and the top plates are 1/4 in. thick. The bottom is of 3/4 in. plates. The bottom or floor plates and the first course were assembled and riveted, resting on rivet kegs directly

over their final location in the concrete foundation, and then lowered to place with hydraulic jacks.

In erecting, the contractor used inside and outside platforms swung from the top of the last plates set up, and for hoisting the plates he used a gin pole bolted to seams in this course. This pole was of such a length that a block at its top was 9 ft. above the top of the plate to which the pole was bolted. The hand winch was located on the ground. Riveting and calking were done with pneumatic machines, a 12 HP. Clayton air compressor (a larger compressor should have been used) and 25 HP boiler being used. For calking a thick edged tool was required, as it made a better joint than a thin edged tool.

The side plates were first set up with bolts, and, when all were in place, the riveting was begun at the top and worked down, except in the case of the lowest two or three courses, when riveting kept pace with erection. The space between the bottom of the pipe and the concrete foundation was filled with neat cement grout, by means of a force pump, through grooves left for the purpose in the concrete foundation. During this process, 6 ft. of water were put into the standpipe to prevent its being lifted.

The actual cost (to the contractor) of the labor on the standpipe was nearly 0.9 ct. per lb., as follows:

	Per lb.
Assembling plates	\$0.33
Riveting	0.42
Calking	0.10
Painting	0.40
Total	\$0.89

The contractor's plant cost about \$1,600. The gang employed was:

- 1 foreman at \$3.50.
- 1 calker at \$3.00.
- 1 riveter at \$2.50.
- 1 engineman at \$2.50.
- 2 heaters at \$2.00.
- 3 helpers at \$1.50.

The contract price for the standpipe was 3.8 cts. per lb. The actual cost to the contractor was 3.88 cts. per lb., as follows:

Materials:	
55 tons steel plates at \$50.....	\$2,750.00
1 ton L iron at \$107.....	107.00
70 kegs rivets at \$2.75	192.50
Bolts used in erection.....	10.00
Moving materials to and from shops and cars	250.00
Freight and materials	180.00
Total	\$3,489.50
Labor:	
Assembling plates	\$ 383.33
Riveting	488.88
Calking	111.95
Painting	47.36
Total	\$1,031.02

Since the total weight of the standpipe was 116,450 lbs., the cost per pound was.

Materials	2.99 cts.
Labor	0.89 cts.
Total	3.88 cts.

The steel standpipe rests on a concrete foundation and is surrounded by a masonry tower. At contract prices the total cost was as follows:

Foundation:	
1,355 cu. yds. excavation.....	\$ 514 90
284 cu yds. concrete (48 ft. diam. X 5 ft. thick)	1,704.00
Grouting under standpipe	133 28
Total, foundation	\$ 2,352.18
Standpipe	4,529.72
Masonry tower	24,790 00
Pipe connections	339.37
Grand total	\$32,011 25

The masonry tower is 77 ft. high, 4 $\frac{3}{4}$ ft. thick at the base, 3 $\frac{1}{2}$ ft. thick at a point 10 ft. above the base, 2 ft. thick at the top. The following are principal items in the tower:

- 925 cu. yds. rubble masonry (granite).
- 275 cu. yds. dimension stone (granite).
- 14 tons iron and steel work.
- 90 sq. yds. granolithic observation roof.

The so-called rubble was laid in courses with $\frac{3}{4}$ -in. joints at the face. Between the tower and the standpipe the contractor erected a staging. Across the top of the standpipe were placed two pairs of 4 x 12-in. timbers, 30 ft. long and trussed with 1 $\frac{1}{4}$ -in. rods. These timbers rested partly on the standpipe and partly on the staging. A platform was laid on these timbers and a guy derrick with a 20 ft. mast and a 30-ft. boom was mounted on the platform.

Cost of Steel Stand Pipe Encased in Brick.—Mr. Edward Flad gives the following data relative to a standpipe built in 1895 at St. Charles, Mo.

The tank is 25 ft. diam., 70 ft. high, and holds 250,000 gals. It is of steel plates ($\frac{1}{4}$ to $\frac{3}{8}$ in. thick) encased in brick, a space of 2 ft. being left between the brick and the steel. It rests on a foundation of natural cement concrete 5 ft. thick. The roof is of steel covered with slate. There are six horizontal circular girders riveted to the steel casing, to provide for wind pressure, acting like the stiffeners of a plate girder. The brick work is 9 ins. thick for the upper 30 ft. and 13 ins. thick for the lower 40 ft., and bears upon the circular girders just referred to. Eight brick pilasters (30 ft. high) were built for architectural effect, brick arches joining the tops of the pilasters. There is a steel cornice with a hand all around the top. A light scaffold was built inside the tank, and a cage swung on the outside, the plates being raised by a gin pole. A forge was placed on the cage and rivets were driven from the inside. After the iron work was in place, the brick casing was built from a scaffold.

The work was done by contract at the following prices:

Steel	\$4,450
Brick casing	2,807
Foundation	678
Total	\$7,935

Brick Casing Around Stand Pipe.—Mr. W. J. Laing gives the following data relative to a brick casing built in 1898 around an iron standpipe to prevent ice formation. The iron standpipe is 26 ft. diam. and 90 ft. high. It rests on a concrete pedestal 62 ft. high, 7 ft. of which is below ground level. This pedestal contains 1,200 cu. yds. concrete. The top of the standpipe is 145 ft. above ground level. The masonry casing around the standpipe is 162 ft. high, and contains 1,275 tons of broken stone, 18 cars of cement, 500,000 brick, and 5,000 lbs. of iron. It required 45,000 ft. B. M. of staging, and 16 men were three months building the casing.

Cost of a Steel Tank and Tower, Ames, Ia.—Mr. A. Marston gives the following relative to 162,000 gallon water tank mounted on a steel tower 110 ft. high, built at Ames, Ia., in 1897. The steel work is 24 ft. diam. x 40 ft. high (excluding the height of a hemispherical bottom). The curved roof is of galvanized iron on a steel frame work. The tank is supported by a tower composed of 4 Z-bar columns (12 in.) resting on 8 concrete pedestals. Each pedestal is 10 ft. square at the base, and 4 ft. square on top, capped with stone 18 ins. thick. The height of each pedestal is 7 ft. below the stone cap, and each contains nearly 18 cu. yds. of concrete. The contract price for the foundations was \$1,156. The contract price for the steel tank and tower was \$8,966, making a total of \$10,116.

Cost of Steel Tank and Tower, Porterville, Calif.—Mr. Philip E. Harroun gives the following data relative to a 75,000 gal. tank on a tower, built in 1904 for the waterworks at Porterville, Calif.

The tank is of steel, 20 ft. diam. x 25 ft. high, plates being $\frac{1}{4}$ to $\frac{5}{16}$ in., and has a hemi-spherical bottom. The tower has four legs 108 ft. long, resting on concrete pedestals. The foundation work was done by day labor at 20 cts. per hr. The tower and tank were erected by contract. The cost was:

157 cu. yds. excav. at 64 $\frac{1}{2}$ cts.	\$ 101.74
52 cu. yds. backfill at 12 $\frac{1}{2}$ cts.	6.46
105 cu. yds. loaded and hauled $\frac{1}{4}$ miles at 20 $\frac{1}{2}$ cts.	21.85
104.7 cu. yds. concrete (materials at \$5.86, and labor at \$1.88), at \$7.74	810.82
65 cu. ft. granite capstones	231.85
78,532 lbs. steel, tower and tank, in place at 0.066	5,191.00
102 ft. screw pipe, 10 in. riser	269.23
Miscellaneous	19.51
Total	\$6,650.81

Cost of Steel Tank and Tower, Fairhaven, Mass.—An elevated water tank was built at Fairhaven, Mass., in 1893. Its capacity is 383,000 gals. and its cost was \$19,000. The steel tank is 35 ft. diam. x 50 ft. high, with a conical bottom, and is supported by 12 steel posts, 97 ft. high, surmounted by a girder 2 ft. high, total

100 ft. Each post rests on a masonry pedestal 9×9 ft. at the base 6×6 ft. at the top, $5\frac{1}{2}$ ft. high, capped with a 4×4 ft. stone $1\frac{1}{4}$ ft. thick.

Cost of Steel Tank and Tower, Providence, R. I.—Mr. F. M. Bowman gives the following relative to a steel water tank and tower built in 1904 for East Providence, R. I. The cost was a little less than \$100,000. The tower is 135 ft. high from base of column to base of tank; the steel tank is 50 ft. diam. \times 70 ft. high, and holds 1,000,000 gals. The foundations are of concrete resting on solid rock.

Cost of Scraping and Painting a Stand Pipe.—Mr. Byron I. Cook says that it is practice to scrape and paint the interior of a stand pipe every two years. An old flat file, ground to a chisel edge, is used for scraping, and it costs less than 0.1 ct. (1 mill) per square yard for scraping. He prefers novices to regular painters. The cost of painting with two coats of Durable Metal Coating was:

Paint	\$0.049 per sq. yd.
Labor	0.042 per sq. yd.

Total\$0.091 per sq. yd.

*The outside of the pipe is not painted oftener than once in five years, with Dixon graphite paint.

Weight of Wooden Tank and Steel Tower.—A steel tower 80 ft. high and supporting a wooden water tank 28 ft. diam. \times 22 ft. high (100,000 gals) weighed 100,000 lbs. This weight of steel included 25,000 lbs. of steel I beams (24 ins.) forming part of the platform on which the tank rested. Brick arches between these I beams formed the platform. The dead load was as follows:

	Lbs.
Tank	25,000
Water	830,000
Platform (brick)	70,000
Platform steel I beams.....	25,000
Tower	75,000
Total	1,025,000

Cost of a Wooden Water Tank, La Salle, Ill.*—The following figures of cost of constructing a wooden water tank are given by Mr. C. H. Nicolet, of La Salle, Ill. The tank was built to replace a tank which failed on March 29, 1905, because of the rusting and bursting of the iron bands or hoops. This old tank was 30 ft. in diameter and 24 ft. high, and was mounted on a circular stone tower 77 ft. high. It was built of Louisiana red gulf cypress, the staves and bottom being 3 ins. thick and the hoops $3/16 \times 6$ ins. and $1/4 \times 6$ ins., with the usual spacing. The new tank was of the same dimensions and type, but with changes in details. The grade of the lumber was raised by limiting the amount of bright sap on any one edge to $1\frac{1}{2}$ ins. This change increased the cost of the wood work about 11%. The most important change, however, was

*Engineering-Contracting, Sept. 26, 1906.

in the style of band used. Round rods were used. There were 29 hoops of $1\frac{1}{2}$ in. diameter and six at the top 1 in. in diameter, all of mild steel. They were spaced 5 ins. apart on centers at the bottom and varying up to 21 ins. at the top. The hoops were made of three 30-ft. rods with a short filling piece, this being the limiting length obtainable from stock. The rods were bent to the proper curve before being placed. The joints were made by means of malleable iron lugs of the type commonly used in built-up stove pipe in the West. The cost of the tank as described was as follows:

Materials:	
Tank complete at mill (wood work only) "Tank grade"...	\$ 628.00

It will be noticed that the labor of putting on the roof is included above, but not the material. This consisted of a flat cover made of $1\frac{1}{2}$ in. tongued and grooved plank resting on 2×12 in. joists tops flush with top of tank, supported on two trucks with cups, and two 6×6 in. posts, each set on tank bottom.

Cost of Concrete Standpipes.*—Mr. George H. Snell, Mr. Frank A. Barbour, and Mr. Leonard C. Wason give the following data relative to a reinforced concrete standpipe built in 1904 at Attleborough, Mass. The standpipe is 50 ft. diam. x 100 ft. high, and holds 1,500,000 gals. The experience, gained with a former standpipe of iron indicated that a steel pipe would have a life of only 20 years, because the water contained carbon dioxide (CO_2). Two tons of rust had been removed annually from a wrought-iron standpipe 30 ft. in diam. x 125 ft. high. The bid on a steel standpipe, 30 ft. x 100 ft., was \$37,135. The bid of the Aberthaw Construction Co. on the reinforced concrete standpipe and gate house was \$34,000, which was accepted.

The concrete wall is 18 ins. thick at the bottom and 8 ins. thick at the top. The bottom is of concrete 1 ft. thick, and the concrete foundation, 18 ins. thick, rests on hardpan 7 ft. below the ground

**Engineering-Contracting*, Dec. 26, 1906.

level. The concrete foundation is of 1:3:6 concrete. The walls are of 1:2:4 concrete, reinforced with round steel rods (0.40 carbon). Rods of milder steel would have been better, for it was difficult to bend them so that they would hold their shape, on account of their springiness. Twisted steel rods could not be bent in true planes and had to be abandoned. The rods were pulled through a tire bender around a curved form by a steam engine. The rods were in 56½-ft. lengths, and were spliced by overlapping 30 ins., using three Crosby guy-rope clips without which it would have been very difficult to secure a satisfactory splice. It was at first attempted to support these hoops, or rings, with vertical rods of twisted steel, but, due to lack of rigidity of these rods, 4-in. channels were substituted, spaced 11 ft. apart. It would have been better had the channels been closer. Holes were punched through the flanges of the channels at proper intervals, and ½-in. pins inserted to support the hoops or rings as in Fig. 21. Up to a height of 60 ft. there were two rings of 1½-in. bars spaced 3¾ to 8 ins. vertically. There were 2½ ins. of concrete outside of the outer ring, and 4 ins. between the two rings. From 60 to 81 ft. there was but one ring.

1½" Rods—

Fig. 21

spaced as shown in Fig. 22. Above 81 ft. the diameter was reduced to 1½ ins.

The labor of bending and placing the steel actually cost \$9 per ton, or 0.45 ct. per lb. The Crosby clips cost 37 cts. each.

The cost of the 1:2:4 concrete in the walls was as follows:

	Per cu. yd.
Cement	\$ 4.80
Sand and stone.	3.90
Mixing concrete ...	0.40
Placing concrete ..	2.20
Forms, labor and lumber....	2.65
480 lbs. steel, assumed at 2 cts.....	9.60
Bending and placing 480 lbs., at 0.45.....	2.16
4 Crosby clips, at 0.37.....	1.48
Total	\$27.19

There are 770 cu. yds. in the walls, which, at \$27.19, gives an actual cost of \$20,936. This does not include the cost of plastering and waterproofing.

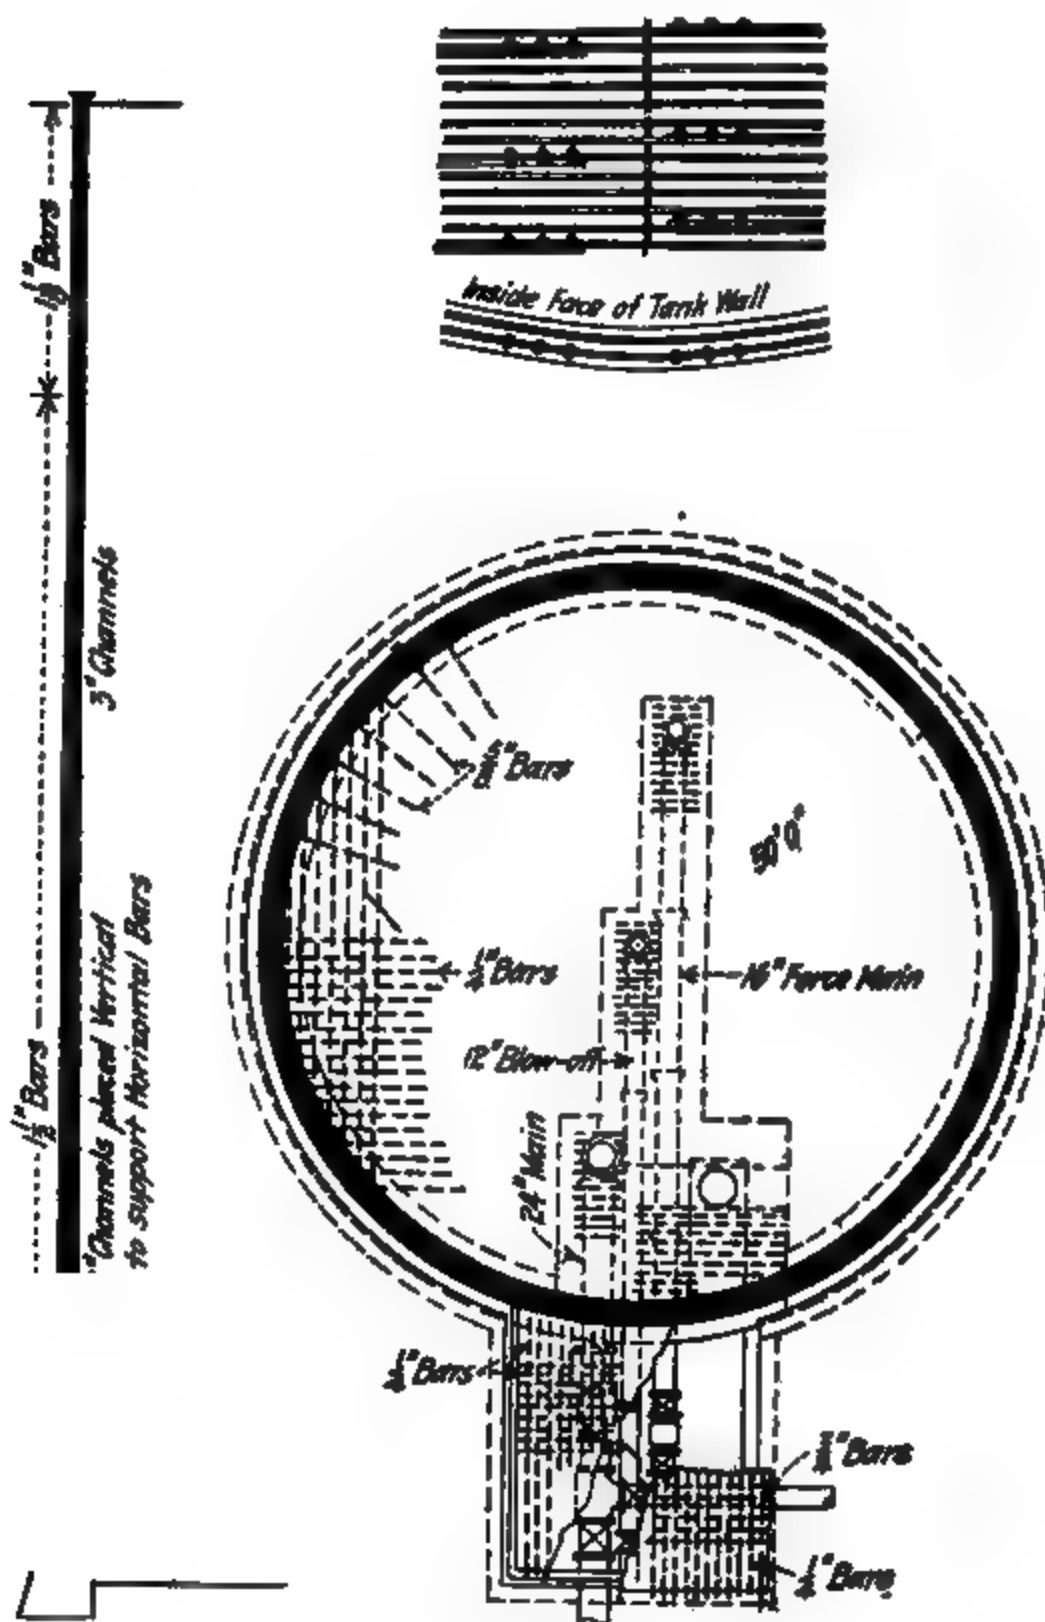

Fig. 22.—Reinforced Concrete Standpipe.

There are nearly 90 cu. yds. in the floor, which are included in the 770 cu. yds. above given. There are about 230 cu. yds. of 1:3:6 concrete in the foundation.

The standpipe has an ornamental concrete cornice and a dome-shaped roof of Guastavino tile.

A timber tower 60 ft. high was erected inside the standpipe and a derrick with a 40-ft. boom was mounted on the tower, the derrick being operated by an engine on the ground. When the standpipe had reached a height of 60 ft., the height of the tower was increased to 110 ft. and the derrick raised. The cost of this tower and of raising the derrick was \$1,700, which is equivalent to \$2.20 per cu. yd. This is charged against the item of forms and of placing concrete.

The plant included a Sturtevant roll jaw crusher, bucket elevator and rotary screen, and a Smith mixer.

The floor and a section of wall $2\frac{1}{2}$ ft. high were molded in one operation, after which the wall was built up in sections $7\frac{1}{2}$ ft. high. The reinforcing was first built up to a height of $7\frac{1}{2}$ ft. and then the forms were placed. The forms were made in sections 11 ft. long. The lagging of the outside forms was boards nailed vertically to wooden ribs. The lagging of the inside forms was boards placed, one at a time, horizontally, as the wall was built up, so that the concrete was always easily accessible. The sections of forms were locked together by iron clamps. Two sets of forms were used, so that one set was left in place while the other was being raised and made ready to receive the concrete. The batter of the outside of the tank increased the difficulty of the work, for they had to be adjusted from time to time to provide for the decreasing circumference. It is questionable whether the cost of this adjusting did not exceed the saving of concrete effected by the use of a batter.

Fig. 23 shows the timber tower and the standpipe partly built.

Fig. 22 shows the design of the standpipe.

Since the wall was built in sections $7\frac{1}{2}$ ft. high, great care was taken to secure a perfect joint between the sections. At the top of each concrete section a groove was formed by a 2 x 3-in. strip of beveled wood. When this was removed, the top surface was well scrubbed with water and coated with neat cement. This joint proved very effective. The operation of placing steel and raising forms for a new section took three days, so that the concrete surface was quite hard when concreting was resumed.

The concrete was dumped on platforms on the tower and shoveled into the forms. Care was taken not to make the concrete so wet that spading and ramming would drive the stone to the bottom and leave porous spots. The mixture must not be more wet than will enable the mortar to support the broken stone. Atlas Portland cement was used throughout.

After the wall had reached a height of 20 ft., the tank was filled

with water, and it was kept filled, as the work progressed, to the elevation of the bottom of the lowest set of forms. Considerable leakage developed at first, but this gradually grew insignificant, although the waterproof coat had not yet been placed. At no time was more than 1 to 2 per cent of the exterior surface wet by leakage. During the winter some of the concrete scaled off near the bottom on the outside, apparently due to cavities outside the steel reinforcement, probably caused by a slight moving of the forms

Fig. 23.—Erecting Concrete Standpipe.

when the concrete was being placed. Repairs were made by digging around the outside rows of steel reinforcement, putting on iron clips ($\frac{3}{4} \times \frac{1}{2}$ in.) of iron bolted through, and then forcing cement into the cavities around the clips by throwing it a distance of 4 ft. against the wall. Expanded metal was then fastened to the clips, and covered with cement plaster, and then more expanded metal was put on over this and plastered.

The inside of the tank was plastered after roughening the surface of the concrete with a pick. The plastering seemed to have

little effect in absolutely stopping the leakage. The lower 25 ft. were subsequently given 5 more coats of plaster without entirely stopping leakage. Finally the surface was treated by the Sylvester process, as follows:

Thoroughly dissolve $\frac{1}{4}$ lb. pure Castile olive oil soap to each gallon of water. Thoroughly dissolve 1 lb. of pure alum in 8 gals. of water. Thoroughly clean the wall and dry it. Apply the soap solution boiling hot, with a flat brush, taking care not to form a froth. Wait 24 hours so that the solution will become dry and hard upon the walls, then apply the alum solution in the same way, at a temperature of 60 to 70° F. Wait 24 hours, and repeat with alternate coats of soap and alum.

In 1870 this process was used successfully to waterproof brick walls on the Croton reservoir, 4 coats of each solution being sufficient; 1 lb. of soap covered 37 sq. ft., and 1 lb. of alum covered 95 sq. ft.

After applying four coats of each solution to the concrete standpipe, up to a height of 35 ft., water was admitted to a height of 100 ft., and only four leaks developed. Then four more coats were applied to this 25-ft. section, and above that only four coats were used.

It was found, by tests at the Watertown Arsenal, that three Crosby clips developed the full tensile strength of the $1\frac{1}{2}$ -in. reinforcing rods.

The design of this tank and further details are given in "Concrete Construction" by Gillette and Hill.

Materials in a Reinforced Concrete Stand Pipe.—Mr. J. L. H. Barr gives the following relative to an 81-ft. standpipe of reinforced concrete built in 1903 at Milford, Ohio.

The outside diameter is $15\frac{1}{2}$ ft. The shell is 9 ins. thick for the lower 30 ft., 7 ins. thick for the next 25 ft., and 5 ins. thick for the remaining 26 ft. The concrete foundation is octagonal, 20 ft. diameter of inscribed circle, and 6 ft. thick. The shell is made of 1:3 mortar (no stone) reinforced with $1 \times 1 \times \frac{1}{4}$ -in. T bars. The vertical bars are 18 ins. c. to c.; the horizontal bars are spaced 6 to the foot for the lower 30 ft., 5 to the foot for the next 25 ft., and 4 to the foot for the remaining 26 ft.

The forms were 3-ft. staves ($1\frac{1}{2} \times 3$ ins.) nailed to circular ribs (4×4 in.), the topmost rib extending 1 in. above the tops of the staves so as to form a rabbit to receive the next form. Three sets of forms were used, each 3 ft. high. Each set consisted of an inner and an outer form, each divided into 8 segments for ease of handling. This standpipe required:

48 cu. yds. gravel containing 40% sand (for base).

90 cu. yds. sand (for shell).

270 bbls. cement.

25,000 lbs. steel.

There would appear to be insufficient steel in the horizontal rings, since the tensile stress at the bottom is nearly 12,000 lbs. per sq. in.

The amount of gravel for the base or foundation appears to be approximately correct, since it would be about 70 cu. yds. of concrete; but the amount of sand appears to be overestimated, as the shell would contain but 60 cu. yds. The base inside the shell was covered with 1:3 mortar 6 ins. deep, which would require about 3 cu. yds.

It is stated that the contract price for this standpipe was \$300 less than the lowest bid for a steel standpipe.

Cost of 12-in. Well, Portersville, Calif.—Mr. Philip E. Harroun gives the following cost of 12-in. well, 216 ft. deep, driven in 1904 at Portersville, Cal. The material penetrated was clay. The contract price for drilling the well and driving the casing was \$2 per lin. ft. The well had a double casing, the inner casing being No. 14 gage, and the outer being No. 16 gage, in 3-ft. lengths. The casing cost \$1 per ft. thus making the total cost \$3 per ft. Various incidentals added \$50 to the cost of the well.

Relative Cost of Waterworks and of Filters.—When it is generally known that it costs about \$100 to produce a million gallons of water in the average city, and less than \$10 to purify it by filtration—including plant interest and depreciation in both cases—there is certain to be far less hesitancy about incurring the expense of providing filter plants. Somehow the impression prevails that pumping water and delivering it through pipes is very cheap, and that filtering is exceedingly expensive, whereas it costs ten times as much to supply water as it does to filter it under ordinary conditions. The expensive system of piping that underlies the streets of a city costs about \$350 per capita of population, whereas a slow sand filter plant capable of supplying 100 gals. per capita per day costs only \$3.50 per capita, and a mechanical filter plant costs less than \$2.70 per capita. In other words, by an expenditure of about 1% more than the first cost of a piping and pumping system for a city of less than 100,000 population a filter plant can be added to the existing water supply system.

It is true that the cost of operating a filter plant is not correspondingly small, but it is a relatively small item nevertheless. As will be seen from the data subsequently given, the principal cost of operating a sand filter is the scraping and cleaning the sand, and replacing it on the filter bed. Year by year, improved methods have been developed for washing and handling the sand, and the end of this development is by no means reached yet.

Cost of Filter and Filtering, Ashland, Wis.—Mr. William Wheeler gives the following relative to a slow sand filter built in 1895 at Ashland, Wis. This was the first sand filter plant in America to be covered with masonry. The 3 filter beds have an area of $\frac{1}{2}$ acre. They are so located on the lake shore that it was necessary to

build a pile bulkhead around three sides of the filter beds. The walls are of concrete and brick, 3 ft. thick at the bottom and 2 ft. at the top. The beds are roofed with groined elliptical brick arches (15½ ft. span), resting on brick pillars, and backed with concrete. Two courses of brick laid flat form the arch rings (5 ins. thick). The floor is of concrete only 3 ins. thick. It is below the lake level, which necessitated building a cofferdam during construction. The sand beds are 4 ft. thick resting on 9 ins. of gravel. The work of construction was entirely by day labor. The cost was as follows:

470 lin. ft. cofferdam (not with earth filling).....	\$ 1,720
Handling water.....	493
8,943 cu. yds. earth excavation.....	3,233
340,400 bricks, laid in walls.....	6,237
45,000 bricks, laid in piers.....	827
349,550 bricks, laid in roof arches.....	6,756
Centers for roof arches (labor and materials).....	1,157
37 manholes.....	724
House over effluent chamber and sump well.....	627
1,000 cu. yds. concrete.....	5,977
Vitrified collecting pipes, laid.....	116
Cast-iron collecting pipes, laid.....	639
Cast-iron supplying pipes, laid.....	725
Pipe, pipe connections, pump, etc.....	729
880 cu. yds. gravel in filter beds.....	1,849
3,385 cu. yds. sand in filter beds.....	4,201
Sundries.....	2,268
Engineering and superintendence.....	1,800

Total\$40,178

This is equivalent to about \$80,000 per acre, but, had it not been for the difficult conditions and winter work, the cost would have been \$5,000 less, or \$70,000 per acre, including pump well, sump well, effluent chamber, piping and housing. A further reduction of 10 to 15 per cent in cost could be effected where building stone and suitable sand and gravel were near at hand.

This plant filtered 1,100,000 gals. per day, or at the rate of 2,200,000 gals. per acre per day. It required 10 scrapings of sand per year, removing 610 cu. yds. of sand, which was equivalent to 1.52 cu. yds. of sand scraped per million gallons. The cost of this scraping was 62 cts. per million gallons, or 40 cts. per cu. yd. of sand, the cost of scraping a bed of one-sixth acre being as follows:

3 men scraping, ½ day, at \$1.50.....	\$2.25
2 men wheeling in filter, ½ day, at \$1.50.....	1.50
1 man tending bucket at bottom, ½ day, at \$1.50.....	0.75
2 men load and dump at bottom, ½ day, at \$1.50.....	1.50
1 man wheeling away at top.....	0.75
1 single team to hoist bucket.....	2.50
Tools and sundries.....	0.50

Total for 1/6 acre..... 8.50

There were 21 cu. yds. of sand (plus the mud) removed at each cleaning of a bed, making the cost 40 cts. per cu. yd. The dirty sand was not washed, but new, clean sand was delivered by contract and placed for \$1 per cu. yd. Hence the cost of scraping sand and of replacing with new sand cost \$1.40 per cu. yd. of sand scraped,

or \$2.13 per million gallons. Adding 13 cts. to this for superintendence, etc., the total cost of filtering was \$2.26 per million gals. At 5 per cent interest on the first cost of the plant, the capital charges are \$5.05 per million gallons, making a total of \$7.31 per million gallons.

Cost of Filter, Berwyn, Pa.—Mr. J. W. Ledoux gives the following data relative to a small ($\frac{1}{2}$ acre) sand filter plant built in 1898 at Berwyn, Pa. It has a nominal filtering capacity of 1,600,000 gals. per day. The filters are built in 3 compartments (not roofed) each having 7,500 sq. ft. effective filtering area, or about 85 ft. square. A vertical section through the filter beds shows 10 ins. of sand, 6 ins. of gravel, 3 ins. of concrete floor and 8 ins. of puddle. The main drains are 12-in. vit. sewer pipe; the laterals are 4-in. tile, spaced 6 ft. apart, set in depressions in the concrete. The side walls are of rubble, outside of which is the embankment. The cost, including a \$2,000 gate house and accessories, was as follows.

6,772 cu. yds. excavation, at \$0.241.....	\$ 1,630.80
528.3 cu. yds. stone masonry, filter basin, at \$5.541.....	2,927.31
2.4 cu. yds. brick masonry, filter basin, at \$9.16.....	21.98
304.5 cu. yds. concrete, filter basin, at \$6.158.....	1,872.43
2,432 sq. yds. plastering and forming gutters, at \$0.243...	591.60
3,200 lin. ft. 4-in. tile drain, in place, at \$0.066.....	207.20
248 lin. ft. 12-in. collecting drain, at \$0.654.....	160.80
286 lin. ft. 12-in. clean-out drain, at \$1.198.....	342.64
281 lin. ft. 12-in. cast-iron inlet and outlet pipes, at \$1.571	441.67
300 lin. ft. 14-in. cast-iron filter discharge, at \$2.192....	658.26
542 cu. yds. puddle, at \$0.709.....	384.63
655.55 tons gravel in filter bottom, at \$2.115.....	1,386.63
2,696.83 tons sand in filter bottom, at \$1.639.....	4,420.10
97.2 cu. yds. stone masonry, gate house, at \$7.284.....	707.07
10.75 cu. yds. brick masonry, gate house, at \$7.28.....	78.28
125.3 cu. yds. excavation and back fill, gate house, at \$0.985.....	123.43
Roofing (slate), woodwork and painting, gate house.....	210.81
9,584 lbs. flange pipe (12-in.), gaskets, etc., at \$0.021....	201.26
Registering and weir apparatus.....	272.45
Valves (6 to 12-in.), with boxes and hand wheels.....	264.89
Superintendence and engineering.....	729.00
Incidentals	1,000.00
Total	\$18,535.59

Since the filter bed has a total area of 22,500 sq. ft., the cost was about 82 cts. per sq. ft. (including cost of the gate house), or \$35,700 per acre. This cost is equivalent to \$12,000 per million gallons of daily capacity. The "superintendence and engineering" was 4 per cent of the total cost.

Cost of Filter, Nyack, N. Y.—Mr. G. N. Houston gives the following relative to a slow sand filter plant built in 1899 at Nyack, N. Y. The filter beds are not roofed. There are two beds 74 x 116 ft. each, having a combined filtering area of 0.35 acre. The maximum consumption of water at Nyack was 430,000 gals. per day, which would require a filtering capacity of 3,300,000 gals. per acre per day, if only one bed were used, but, in practice, both beds are used except when one is being cleaned. The raw water is drawn by gravity from a nearby creek. The filter is located in a swamp.

adjacent to the creek, which made its construction expensive. In order to deliver the creek water by gravity to the filter, it was necessary to excavate for the filter beds to a depth of 10 ft. The material was a wet tenacious clay whose banks would crack and slip, so that it was necessary to support the side walls on piles. The clay was spaded out in chunks that were lifted by hand into wagons. Temporary plank roads had to be laid. Sheet piles were driven all around the filter beds and left in place. Bents of bearing piles were driven underneath the retaining walls, capped and floored with plank. On this pile foundation, which cost \$3 per lin. ft. of wall, was built a small concreted retaining wall for a height of 3 ft. 8 ins., the top of this wall being about the same elevation as the top of the sand in the filter bed. The earth slope above the retaining wall was paved with 8 ins. of concrete and vitrified brick for a length of about 6 ft. measured up the $1\frac{1}{2}$ to 1 slope. The division wall was also supported on a pile foundation, and was of concrete up to the level of the surface of the filter sand, and above that it was of vitrified brick 2 ft. thick. The work was done by contract at the following cost to the village:

Excavation (10½ ft. deep and about 7,000 cu. yds.).....	\$ 6,270
Grading and soiling	1,500
Sheet piles, 66,000 ft. B. M., at \$50.....	3,300
Bearing piles, 352, at \$4.42.....	1,568
Hemlock caps and floor.....	838
Yellow pine caps and floor.....	465
Concrete floor, 10½ ins. thick (\$1.50 per sq. yd.).....	2,738
Concrete walls, 430 cu. yds., at \$4.40.....	1,892
Concrete slope paving.....	484
Brick slope paving, 13.45 cu. yds., at \$8.40.....	113
Blue-stone curb	250
Vitrified pipe drains (about 1,400 lin. ft. of 6-in. and 230 ft. of 15-in.).....	347
Gravel (12 ins.) and sand (36 ins.), 2,670 cu. yds., at \$2.15.	5,524
House over regulating chamber.....	150
Pipe laying	58
Miscellaneous	250
Total	\$24,737
Engineering (\$3,644) and inspection (\$713).....	4,357
Total, 0.38 acres, at \$76,553.....	\$29,094

This is an unusually high cost, due to the conditions above given, and to the fact that the work was dragged along, which made the expense of engineering and inspection high. The price of filter gravel and sand was high, as it was brought by scow from Long Island.

The above costs include a clear water well 25 ft. in diameter, with side walls 12 ft. high, and a dome-shaped roof of concrete.

The plank "floor" includes not only the floor laid on the bearing piles, but a 1-in. hemlock floor laid over the entire bottom of the filter bed on which the concrete was placed.

Cost of Filter and Filtering, Superior, Wis.—Mr. R. D. Chase gives the following data relative to a sand filter and aeration plant built in 1899 for Superior, Wis., to remove the iron from water from

driven wells. There are 3 filter beds, each 67 x 108 ft., and with these in operation there is 0.5 acre filtering area, with a capacity of 5,000,000 gals. daily, or 10,000,000 gals. per acre per day. This rapid rate of filtration is justified because there is no mud or bacteria.

The pure water reservoir is 39 x 108 ft. The floor, sides and roof are of concrete, the piers supporting the roof being of brick 20 ins. square and 12 ft. high. The floor is of inverted groined arches, and the roof is of groined arches, 12 ft. span and 2½ ft. rise, 6 ins. thick at the crown. The roof is covered with 2 ft. of earth.

The excavation was red clay, expensive to handle, the actual cost being 55 cts. per cu. yd.

Each filter bed has 20 manholes, 3 ft. diam., 3 ft. high, of concrete 8 ins. thick, with double covers of steel plates.

The outside walls of the filter beds are 2½ ft. thick at the top, and 3¾ ft. thick at the base.

The construction of the pure water reservoir is similar to that of the filters, and the reservoir has a capacity of 300,000 gals.

The main underdrains are 20-in. tile, laid in concrete beneath the floor. The lateral drains are of 6-in. tile, 12 ft. apart. The gravel was dredged from the lake. Under normal conditions 4 ft. of water is kept on top of the sand.

The outside dimensions of the 3 filter beds and the pure water reservoir, all under one roof, are 116 ft. x 255 ft.

The construction was done by day labor, working under a contractor who was paid a percentage for supervision. Laborers were inefficient, yet received \$2 a day. The actual cost was as follows:

Filters and pure water reservoirs:	
14,000 cu. yds. excavation, at \$0.55+	\$ 7,630
2,000 cu. yds. backfill (roof, etc.), at \$0.30+	600
3,000 cu. yds. concrete, at \$7.85+	23,500
Arch centering	1,910
120 cu. yds. brickwork, at \$10.00	1,200
Tile pipe	860
600 cu. yds. filter gravel, in place, at \$4.95	2,970
1,600 cu. yds. filter gravel, in place, at \$3.04	4,864
800 cu. yds. filter gravel, in place, at \$0.97	776
Aerator	470
Miscellaneous charges	2,350
Engineering and percentage to contractor	9,204
Total	\$56,334
Land	6,280
Iron pipe, pump, pump house, etc.	26,870
Grand total	\$89,484

Since the total area was $116 \times 255 = 29,580$ sq. ft. (0.68 acre), the excavation must have averaged about 13 ft. deep.

It will be noted that the filter gravel was exceedingly expensive, as was most of the filter sand. The sand for one bed, however, was obtained without dredging and at a cost of only 97 cts. per cu. yd.

The cost of cleaning a filter bed is as follows:

5 men scraping, 3 hrs., at 20 cts.....	\$ 3.00
1 team hoisting, 2 hrs., at 40 cts.....	0.80
5 men hoisting, 2 hrs., at 20 cts.....	2.00
5 men smoothing, 2 hrs., at 20 cts.....	2.00
Total, labor, 10 cu. yds., at \$0.78.....	\$ 7.80
10 cu. yds. new sand to be replaced, at \$1.....	10.00
Grand total, 10 cu. yds., at \$1.78.....	\$17.80

About 12,000,000 gals. are filtered through each bed (0.25 acre) between scrapings, so that 0.83 cu. yd. of sand is scraped per million gallons, and the cost per million gallons is:

Labor scraping and removing sand.....	\$0.85
Clean sand replaced.....	0.83
Total	\$1.48

The dirty sand is hoisted in tugs by a team, a tripod with a block and tackle being placed temporarily over each manhole during hoisting.

Cost of Filter and Filtering, Washington, D. C.—Mr. Allen Hazen and Mr. E. D. Hardy give the following data:

This is a slow sand filtration plant treating 70,000,000 gals. daily, and its cost was \$3,356,300 (including \$619,900 for land), or \$47,950 per million gallons daily capacity. Assuming interest and depreciation at 5 per cent per annum, the capital charge is \$7 per million gallons, for an average of 67,000,000 gals. per day, and the operating expense is about \$2 per million gallons, making a total of \$9 per million gallons filtered.

The summarized cost of the plant is as follows:

Pumping station, etc.....	\$ 183,600
29 filters, 29 acres, at \$75,758.....	2,197,000
Filtered water reservoir.....	150,000
Lower gate house and pipe line.....	24,300
Land	619,900
Engineering and clerical	181,500
Total, 29 acres, at \$115,735.....	\$3,356,300
Total, exclusive of land.....	2,736,400

The detail cost was as follows:

Pumping Station:

Intake, with gates and building.....	\$ 11,500
Venturi meters, 72-in. and 54-in.....	5,000
Electric lighting, engines, etc.....	7,000
Four 200-hp. boilers, in place.....	14,800
Four Roney stokers.....	4,100
Two Green fuel economizers, in place ..	5,100
Three 36-in. centrifugal pumps and engines.....	42,000
Two sand-washer pumps.....	8,100
Piping, valves, etc.....	13,100
Coal, oil and running tests.....	3,500
Traveling crane	1,800
Chimney (with foundation).....	5,800
Building (with foundation and well).....	51,000
Total, pumping station	\$183,600

Twenty-nine Filters:

862,700 cu. yds. excavation, at 30 cts.	\$ 258,800
299,500 cu. yds. filling, at 30 cts.	89,900
Sodding and seeding slopes.	7,300
Roads and drains outside of filters.	16,200
Concrete tunnel under First St.	3,100
Concrete (including cement):	
36,563 cu. yds., floors, at \$6.75.	246,800
19,038 cu. yds., walls, at \$7.35.	139,900
6,964 cu. yds., piers, at \$8.25.	57,500
34,920 cu. yds., roof (vaulted), at \$8.75.	305,500
Ramps leading to tops of filters.	6,800
Court paving.	43,000
7,900 ft. Central underdrains, at \$1.65.	13,000
Interior drainage system, 29 filters, at \$500.	14,500
Drainage of roofs, 29 filters, at \$266.	7,700
Materials placed in concrete, 29 filters, at \$200.	5,800
157,725 cu. yds. filter sand, at \$2.65.	418,000
36,500 cu. yds. filter gravel, at \$2.75.	100,400
Cast-iron pipe and specials.	117,000
Steel rising main and concrete backing.	76,800
Pressure pipe system.	2,600
Sand-washer pipe system.	24,000
Sand washers, 19 washers and 8 ejectors.	4,800
Elevated sand bins, 29 capacity 250 cu. yds. each.	60,800
Exterior drainage system.	25,300
Venturi meters and indicating apparatus.	11,400
Sluice gates and gate valves.	19,900
Regulator houses.	27,300
Office and laboratory.	19,700
Shelter house for workmen.	4,800
Water and gas lines to buildings.	11,200
Electric lighting for courts and filters.	41,900
Cleaning up and miscellaneous.	11,600

Total, filters, 29 acres, at \$75,758.....\$2,197,000

Filtered Water Reservoir:

83,500 cu. yds. excavation, at 30 cts.	\$ 25,100
18,000 cu. yds. filling, at 30 cts.	5,400
15,290 cu. yds. concrete, at \$7.60.	116,000
Gate house superstructure.	3,500

Total, reservoir\$150,000

Lower Gate House.

Pipe lines	\$ 6,000
Gate house	18,300

Total, gate house.....\$ 24,300

Engineering and Clerical.

General plans	\$ 36,000
Surveying	32,000
Field office force	21,000
Main office force	67,000
Watchmen	4,500
Temporary office	1,000

Total engineering\$181,500

The engineering was 6.65 per cent of the total cost of construction, which is a high percentage on so large a contract.

This Washington filter plant is similar to the Albany plant, but

It cost 65 per cent more per acre, due principally to the higher contract prices, especially the price for filter sand which cost \$2.65 per cu. yd. at Washington as compared with \$1 per cu. yd. at Albany. It was anticipated by the Washington contractors that the cost of producing filter sand of specified cleanliness would be far greater than it really was.

Cost of Filtering at Washington, Albany and Philadelphia.—Mr. J. A. Vogleson gave the following table of cost of cleaning filter sand per cubic yard:

	—Philadelphia—			
	Washington (1906).	Albany (1899-1901).	Belmont (1905).	Upper Roxboro' (1906)
Scraping	\$0.05	\$0.13	\$0.21	\$0.18
Removing	0.16	0.25	0.23	0.22
Washing	0.05	0.30	0.30	0.09
Replacing	0.13	0.25	0.25	0.30
Total, per cu. yd.	\$0.39	\$0.93	\$0.80	\$0.79
Rate of wages, per 8 hrs.	\$1.50	\$1.50	\$1.75	\$1.75
Cost, per million gals. .	\$0.60	\$1.66	\$1.25	\$0.63

The low cost of cleaning Washington filters is due to the method used. After scraping the sand into piles, it is shoveled into an ejector and carried through a hose to a 4-in. pipe, and thence to the sand washers, and thence through pipes to the sand bins, from which it is drawn off into carts and dumped through the roof of the filter into a rotatable chute which discharges it where desired.

The cost of 30 cts. per cu. yd. for "replacing" the sand at Upper Roxboro, Philadelphia, is the contract price, the work being done with wheelbarrows. Before the replacing was done by contract, it cost the city 52 cts. per cu. yd. by day labor, thus furnishing another one of the numberless examples of the greater efficiency of contract labor.

Cost of Filter and Filtering, Albany, N. Y.—Mr. Allen Hazen describes the slow sand filter plant built at Albany, N. Y., in 1898-1899, giving the following data:

The plant has a capacity of 14,700,000 gals. per day, and its first cost was \$500,000, including the pumping plant. There are 8 filter beds of 0.7 acre filtering area each (121 x 258-ft. bed), and with one bed out of use for the purpose of being cleaned the yield of the 7 beds is 14,700,000 gals. daily, or 3,000,000 gals. per acre of bed in active service. The water is pumped from the Hudson River into a 5-acre (14,600,000-gal.) sedimentation basin (380 x 600 ft.), 9 ft. deep, the 2 centrifugal pumps having a total capacity of 24,000,000 gals. per 24 hrs. against a lift of 24 ft. Half of the pumping plant is capable of supplying the ordinary consumption. The clean water reservoir holds only 600,000 gals., being very small because the old distributing reservoirs are used to store the filtered water after it is pumped from the clear water reservoir.

The cost of this plant, in round numbers, was as follows:

Sedimentation basin	\$ 60,000
Clear water reservoir.....	8,000
Filters (at \$45,600 per acre).....	255,000
Pumping station	50,000
Conduit from filter to pumping station.....	87,000
Engineering, laboratory equipment, etc.....	31,000
Total	\$493,000
Land	8,000
Grand total	\$500,000

This is equivalent to nearly \$35,000 per million gallons of daily capacity. Strictly speaking, the conduit from the filter to the pumping station should not be included, and, if its cost (\$87,000 is deducted, we have a cost of about \$30,000) per million gallons of daily capacity.

The plant was built by contract, and the following is a more detailed statement of the cost to the city.

Filters, Sedimentation Basin and Pure Water Reservoir:

Preliminary draining	\$ 1,956.71
70,672 cu. yds. excavation, at \$0.308	21,761.64
16,040 cu. yds. rolled embankment, at \$0.53	8,340.80
22,861 cu. yds. silt and loam filling, at \$0.15	3,427.65
23,439 cu. yds. general filling, road, at \$0.18	4,219.02
12,550 cu. yds. puddle, at \$0.715	8,973.25
1,775 cu. yds. gravel lining, at \$0.85	1,508.75
2,257 sq. yds. split stone lining, at \$0.82	1,850.74
11,737 cu. yds. concrete in floors, at \$2.31	27,112.47
7,792 cu. yds. concrete in roof vaulting, at \$3.85	29,999.20
3,147 cu. yds. all other concrete, at \$2.13	6,703.11
4,382 cu. yds. brick work, at \$8.125	35,603.75
31,715 bbls. Portland cement, at \$1.935	61,368.53
7,281 cu. yds. filter gravel, at \$1.05	7,645.05
36,488 cu. yds. filter sand, at \$1.00	36,488.00
Cast-iron pipes and specials	21,841.25
Gates and valves	6,714.23
672 filter manhole covers, at \$4.40	2,956.80
8 sand run fixtures, at \$407.50	3,260.00
8 regulator houses, at \$862.24	6,897.92
1 office and laboratory	4,881.00
Vitrified brick paving	2,158.00
Iron fence about court	1,704.00
Extra work and minor items	8,692.01
Total	\$224,217.20

The excavation averaged 4 ft. deep. The 6-in. vitrified drains were placed 14 ft. apart. The main vitrified drains (12 to 30 in.) were placed beneath the concrete floor, being bedded in concrete.

The price for concrete does not include the Portland cement, which is a separate item. The concrete was mixed 1:3:5, a barrel being 38 cu. ft., and required 1.26 bbls. cement per cu. yd.

The actual cost of the concrete is given on p. 748.

The floor of the filter was of concrete, built in the form of inverted grained arches to distribute the pressure over the subsoil. The roof was of concrete, grained arches (6 in. thick at crown, span 12 ft., rise 2½ ft.), supported by brick piers 21 in. square by

9½ ft. high. The outside walls were of concrete lined with 8 ins. of brick, and the division walls were of brick.

The gravel and sand were dredged from the river with a dipper dredge having a daily capacity of 500 cu. yds., but the average output was 390 cu. yds. The sand was pumped into a stock pile.

According to Mr. W. B. Fuller the cost of roofing the filter was about 30 per cent of the total cost of the filters, or \$13,700 per acre, or 31½ cts. per sq. ft. This includes not only the brick piers and earth covering over the roof, but the extra thickness of the floor necessary to carry the added load.

The cost of one section of concrete floor, brick piers and concrete roof, 13 ft. 8 ins. square (187 sq. ft.), at contract prices was:

4.85 cu. yds. floor, at \$4.75.....	\$23.04
1.24 cu. yds. brick, at \$9.67.....	11.99
5.40 cu. yds. roof, at \$6.30.....	34.02

Total, 187 sq. ft., at 36.9 cts.....\$69.05

This gives an average thickness of 7 ins. of concrete in the floor. Deducting the cost of the floor, we have left 25 cts. per sq. ft. as the cost of the piers and the roof. This does not include the cost of the 2-ft. earth fill over the concrete roof, which added about 10 cts. per sq. ft., the price of the silt fill being only 15 cts. per cu. yd. This roof was entirely effective in preventing freezing.

A reinforced concrete roof was considered, but was not adopted because the city water board objected to anything "experimental."

The cost of operating the filter plant from September 5 to December 25, 1899 (118 days), was \$1.67 per million gallons, for 12,500,000 gals. per day.

The following was the ordinary force of men:

	Per day.
10 laborers, at \$1.50 for 8 hrs.....	\$15.00
1 foreman	2.75
1 watchman	1.50
Total labor	\$19.25
1 chemist	3.00
Total	\$22.25

The cost of pumping was \$2.52 per million gals., the following being the daily cost:

3 engineers, at \$2.48.....	\$ 7.44
3 firemen, at \$1.98.....	5.94
3 tons coal, at \$2.72.....	8.16
1 laborer, at \$1.50.....	1.50
9 gals. engine oil, at \$0.09.....	0.81
2 gals. cylinder oil, at \$0.11.....	0.22
6 gals. kerosene, at \$0.10.....	0.60
5 lbs. waste, at \$0.07.....	0.35
Steam packing, sheet rubber, soap, soda, maps, cloths, etc.....	6.58
Total	\$31.50

Neither of the above costs for filtering or pumping include interest, depreciation and repairs.

The amount of sand scraped and cleaned was 0.7 cu. yds. per million gallons. The labor cost was as follows per cubic yard:

1.44 hrs. of man scraping, at 18% cts.....	\$0.270
2.63 hrs. of man wheeling, at 18% cts.....	0.493
2.44 hrs. of man washing, at 18% cts.....	0.458
1.92 hrs. of man refilling, at 18% cts.....	0.360
8.43 Total	\$1.581

This is equivalent to \$1.19 per million gallons, exclusive of foreman's time, cost of wash water, etc. The volume of water for washing the sand was about 13 times the volume of the sand. About $\frac{3}{8}$ in. of sand (not including the mud) was scraped off at each scraping, requiring 76 hrs. of a man's time to scrape an acre. The sand was wheeled out in barrows averaging only 1 cu. ft. per barrow load, the average haul being 300 ft. from point of loading to the sand washer. The filters yielded 66,600,000,000 gals. per acre between scrapings.

The sand is washed in sand washers of the ejector type, there being 5 ejectors in each sand washer through which the dirty sand must pass.

Mr. Geo. I. Bailey gives the following relative to the cost of filtering through slow sand filters at Albany, N. Y., and at Lawrence, Mass., both being for the year 1899:

	Albany (\$,817 million gals.)	Lawrence (1,170 million gals.)
Ice cutting and snow.....	\$1.91
Scraping sand	\$0.25
Scraping and replacing sand.....	3.18
Wheeling out	0.50
Washing sand	0.59	1.25
Conveying sand	1.31
Refilling	0.39
Incidentals	0.20	0.43
Repairing elevator and tools.....	0.11
Cleaning basin	0.06
Total	\$1.99	\$8.19

Interest and depreciation are not included, nor is pumping. The Lawrence plant makes a miserable showing. Scraping and replacing includes scraping the beds, wheeling to a roadway, and carrying the sand back from the washing machine and spreading on the beds. Conveying sand means loading and transporting it (470 ft.) from the roadway to the washing machine. Wages were 25 cts. per hr.

The Albany plant was operated 319 days (July 26, 1899, to July 1, 1900), giving nearly 12,000,000 gals. per day. Labor was paid 18% cts. per hr. The daily average was 2,630,000 gals. per acre. The average run was 66,600,000 gals. per acre between cleanings. There were 5,200 cu. yds. of sand and mud wheeled out (yielding 3,687 cu. yds. washed sand), and 3,500 cu. yds. of washed sand wheeled back. Each barrow wheeled out contained 2 cu. ft. (71,703 wheelbarrow loads), and each barrow wheeled back contained 1.6 cu. ft. (59,590 barrow loads). Hence there were practically 1 cu.

yd. of washed sand per million gallons, and the above costs per million gallons at Albany are also practically the costs per cubic yard of sand handled.

The following is the cost for the 319 days at Albany (add 15 per cent for a full year's cost of wages, etc., but also add 15 per cent to the amount filtered):

Filter:	
Labor.....	\$5,107.62
Superintendence	1,392.58
Tools and supplies.....	377.75
Half the cost of miscellanies.....	304.75
Wash water for sand at 1 ct. per 100 cu. ft.....	209.06

Total, at \$1.94 per million gals.....\$7,391.76
(Add 5 cts. per million gals. for cleaning sedimentation basin.)

Pumping:	
Engineers and firemen.....	\$4,258.65
Laborers	387.00
Coal and supplies.....	3,497.84
Oil, packing, etc.....	799.06
Half cost of miscellanies.....	304.75

Total, at \$2.42 per million gals.....\$9,247.30

Laboratory:	
Chemist	\$ 999.96
Laborer	69.28
Laboratory supplies	245.15

Total, at \$0.34 per million gals.....\$1,314.49

Total cost per million gals., incl. pumping, but not incl. capital charges\$ 4.76

Mr. John H. Gregory gives the following relative to the Albany filter plant operation, during 1899 to 1900, covering a period of 500 days.

Scraping required 0.69 hrs. labor per cu. yd., or 13 cts. per cu. yd. of sand. There were 1.23 cu. yds. of sand scraped (to a depth of 0.66 in.) per million gallons, so that the cost of scraping was 16 cts. per million gallons. This covers only the labor cost of scraping the dirty sand into piles.

Wheeling out the sand includes shoveling it into barrows, wheeling it 250 ft., and raking and screeding the filter bed. Its cost was 1.29 hrs. labor, or 25 cts. per cu. yd.; and, since there were 1.23 cu. yds. per million gals., the cost of wheeling was 30 cts. per million gallons. The raking and screeding of the bed consumed about 25 per cent of the time of the men engaged in shoveling and wheeling, one man raking and screeding 11,000 sq. ft. per day.

Washing the sand includes handling the dirty sand from the storage piles to the sand washer, attendance on the washer, and removing the washed sand to a storage pile. The ejector type of washer was used. The cost was 1.57 hrs. labor, or 30 cts. per cu. yd. of sand, or 27 cts. per million gallons filtered.

Refilling filter beds with clean sand includes removal from storage piles to filter bed, loosening the top layer of sand about 6 ins. deep, and leveling the new sand. Its cost was 1.31 hrs. labor, or 25 cts. per cu. yd., or 22 cts. per million gallons.

Mr. George I. Bailey gives the cost of filtering at Albany, for the year 1900:

Labor	\$ 6,131.63
Incidentals	574.92
Lost time	451.32
Superintendence	2,161.43
Supplies	552.25
Supplies, miscel.	604.84
Wash water	226.92
Total	\$10,703.31

	Hours.	Total.	Per million gals.
Scraping	5,481	\$ 1,532.70	\$0.24
Wheeling out	10,238	2,862.20	0.45
Refilling	7,437	2,081.66	0.32
Incidentals	3,009	841.25	0.13
Lost time	2,365	642.10	0.10
Washing	8,923	2,722.40	0.42
Total	37,453	\$10,703.31	\$1.66

The equiv. cost per cu. yd. of sand was:

Wheeling out	\$0.26
Refilling	0.37
Washing	0.48

Wages are \$1.50 per 8-hr. day.

The round trip is 500 ft. from the filter bed to the storage piles.

In scraping, a long-handled shovel with a blade 12 ins. wide enables a man to scrape more than 100 sq. yds. per hr.

It was found that one run plank 14 ins. wide gives better service than two 10 to 12-in. planks, and it takes half as long to place the single plank.

The wheels of the ordinary wheelbarrows were readjusted so as not to put so much weight on the arms of the men in ascending grades.

The men shovel the dirty sand from the storage pile into a movable hopper, whence the sand is carried by a current of water through a pipe to the washer, thus saving wheeling it to the washer. Men wheel the sand away from the washer.

The average run is 26 days between scrapings, or 70,000,000 gals. per acre, $12\frac{1}{2}$ parts of water to 1 part of sand are used in washing, costing 4 cts. per cu. yd. of sand.

Cost of Groined Arches and Forms on the Albany Filter Plant.—The following data are given by Mr. Allen Hazen and Mr. William B. Fuller. The concrete was mixed in 5-ft. cubical mixers in batches of 1.6 cu. yds. at the rate of 200 cu. yds. per mixer day. One barrel of cement, 380 lbs. net, assumed to be 3.3 cu. ft., was mixed with three volumes of sand weighing 80 lbs. per cu. ft., and five volumes of gravel weighing 100 lbs. per cu. ft. and having 40% voids. On the average 1.26 bbls. of cement were required per cu. yd. The conveying plant consisted of two trestles (each 900 ft. long) 730 ft. apart, supporting four cableways. The cables were attached to carriages, which ran on I-beams on the top of the trestles. Rope drives were used to shift the cableways along the trestle. Three-ton loads were handled in each skip. The installa-

tion of this plant was slow, and its carrying capacity was less than expected. It was found best to deliver the skips of concrete to the cableway on small railway track, although the original plan had been to move the cableways horizontally along the trestle at the same time that the skip was traveling.

The cost of mixing and placing the concrete was as follows;

	Per cu yd.
Measuring, mixing and loading.....	\$0.20
Transporting by rail and cables.....	0.12
Laying and tamping floors and walls, including setting forms	0.22
Total	\$0.54

The cost of laying and tamping the concrete on the vaulting was 14 cts. per cu. yd. The vaulting is a groined arch 6 ins. thick at the crown and 2½ ft. thick at the piers.

The lumber of the centering for the vaulting was spruce for the ribs and posts, and 1-in. hemlock for the lagging. The centering was all cut by machinery, the ribs put together to a template, and the lagging sawed to proper bevels and lengths. The centers were made so that they could be taken down in sections and used again. The cost of centering was as follows:

Labor on centers covering 62,560 sq. ft.:	
Foreman, 435 hrs. at 35 cts.....	\$ 152.25
Carpenters, 4,878 hrs. at 22½ cts.....	1,096.42
Laborers, 3,447 hrs. at 15 cts.....	517.05
Painters, 577 hrs. at 15 cts.....	86.55
Teaming, 324 hrs. at 40 cts.....	121.60

Total labor building centers 313 M at \$6.37.....\$1,973.87

Materials for centers covering 62,560 sq. ft.:	
213,000 ft. B. M. lumber, at \$18.20.....	\$5,700.00
3,700 lbs. nails, at 3 cts.....	111.00
8 bbls. tar, at \$3.....	24.00

Total

These centers covered two filters, each having an area of 121½ x 258 ft. There were six more filters of the same size, for which the same centers were used. The cost of taking down, moving and putting up these centers (313 M) three times was as follows:

Foreman, 2,359 hrs. at 35 cts.....	\$ 825.65
Carpenters, 12,766 hrs. at 22½ cts.....	2,872.35
Laborers, 24,062 hrs. at 15 cts.....	3,609.30
Team, 430 hrs. at 40 cts.....	172.00
3,000 ft. B. M. lumber, at \$20.....	60.00
3,000 lbs. nails, at 3 cts.....	90.00

Total cost moving centers to cover 196,660 sq. ft.

The cost of moving the centers each time was \$8.10 per M, showing that they were practically rebuilt; for the first building of the centers, as above shown, cost only \$6.37 per M. In other words, the centers were not designed so as to be moved in sections as they should have been. Although the centers were used four times in all, the lumber was in fit condition for further use. The cost of the labor and lumber for the building and moving of these cen-

ters for the 8 filter beds, having a total area of 359,220 sq. ft., was \$16,428, or 6 cts. per sq. ft.

Cost of Filter and Filtering, Lawrence, Mass. — Mr. Morris Knowles and Mr. Charles G. Hyde give the following data relative to the slow sand filter plant built in 1892 at Lawrence, Mass. The plant was built by day labor and cost \$80,000. It consists of 25 filter beds, having a total filtering area of 2.36 acres, so that the cost of the plant was \$34,000 per acre. The raw water enters the filter from the Merrimac River by gravity. The filters are not roofed, although, as will be seen later on, the cost of roofing is abundantly justified by the cost of ice removal.

Between the years 1897 and 1900, inclusive, the beds were scraped 16 times yearly. The average depth of sand removed at each scraping was $\frac{3}{4}$ in., making a total of about 3,500 cu. yds. of sand yearly over the entire surface. About 1,200,000,000 gals. per year, or 3,500,000 gals. per day, were filtered during this period, which is equivalent to only 1,400,000 gals. per acre per day, or about half what a modern slow sand filter delivers. Nearly 3 cu. yds. of sand were scraped per million gallons filtered, which is far in excess of amount ordinarily scraped.

The cost per million gallons for the year 1900, which was typical, was as follows:

Scraping sand	\$1.76
Sanding	1.02
Conveying sand	1.16
Washing sand	1.25
Removing snow and ice.....	1.93
General	0.60
Total	\$7.70
Add (5% of \$80,000) ÷ 2,100 mill. gals.....	1.90
Total	\$9.60

The capital charge of \$1.90 per million gallons is none too high, and takes into consideration no charge for "special repairs."

In this year of 1900, 3,000 cu. yds. of sand were scraped off in filtering 2,100 million gals., or 2.48 cu. yds. per million gallons, hence the above figures of cost per million gallons if divided by 2.48 will give the cost per cubic yard of sand handled, or:

Scraping	\$0.70
Conveying	0.46
Washing	0.50
Sanding	0.40
Total per cu. yd.....	\$2.06

Scraping includes not only scraping off the dirty sand and throwing it into small piles, but loading and wheeling (75 to 150 ft.) in barrows to a temporary dump just inside the filter bed. It also includes smoothing the beds after cleaning.

Conveying including loading the dirty sand from the temporary dumps into carts and hauling and depositing in a permanent dump near the washer.

Washing includes screening dirty sand, washing and transporting to the stock pile of clean sand.

Sanding includes cost of loading and wheeling in the clean washed sand and spreading it.

Wages of laborers were \$2 per 9-hr. day.

The sand washer consists of 4 hoppers. The sand drops to the bottom of each hopper, where it strikes a horizontal jet of water and is carried into a pipe that leads up into the next hopper. The water required is about 10 times the volume of sand, or 270 cu. ft. of water per cu. yd. of sand. Four men attend to screening and wheeling to the washer, washing and taking the sand away in dump cars; they can thus wash 21 cu. yds. of sand daily at a cost of \$8 for labor, or 38 cts. per cu. yd., but delays due to shifting of the washer, etc., and cost of repairs make a total cost of 50 cts. per cu. yd.

Mr. M. F. Collins, superintendent of the plant, states that the average depth to which the sand is scraped is greater for an un-roofed filter than for one that is roofed, due to the fact that when there is any snow on the filter bed the men usually scrape too deep with their shovels, and when the bed is frozen slightly they necessarily must take off an excess of sand to get below the frost. Possibly this accounts largely for the abnormally great amount of sand scraped at Lawrence; possibly the method of scraping is itself not what it should be.

Mr. John H. Gregory gives the following additional information for 1900. The cost per million gals. was as follows, labor being separated from materials, supplies, etc., and from superintendence:

Scraping (labor)	\$1.50
Conveying (labor)	1.02
Washing (labor)	0.94
Sanding (labor)	0.90
Removal of snow and ice (labor).....	1.56
General (labor)	0.33
Superintendence	0.31
Materials, supplies, etc.....	0.52
Total	\$7.78

He states that 1.94 cu. yds. were scraped per million gals. filtered, requiring 3.53 hrs. labor per cu. yd., or 77 cts. per cu. yd., wages being \$2 for 9 hrs., average thickness scraped being $\frac{1}{2}$ in.

He states that 3,000 cu. yds. were washed in 1900, at a cost of 38 cts. per cu. yd. for labor, requiring 1.72 hrs. labor per cu. yd.

He states that 3,400 cu. yds. of clean sand were put on, at a cost of 32 cts. per cu. yd. for labor, or 1.47 hrs. labor per cu. yd.

From the year 1898 to 1900, inclusive, the average cost of snow and ice removal was \$2.20 per million gals., or nearly \$1,100 per acre per annum. Since an acre could be roofed for about \$15,000, it is evident that it would be much cheaper to pay interest on a roof. However, the Lawrence filters show about half the ordinary output of water per acre attained by well designed beds, so that if their filtering capacity per acre were doubled, the cost of snow and ice removal would be \$1.10 per million gals.

Cost of Filter and Filtering, Vernon, N. Y.—A slow sand filter was built at Mt. Vernon, N. Y., in 1894, at a cost of about \$25,000. The area of the filter beds is 1.1 acres, and about 1,900,000 gals.

were filtered per day. The average cost of filtering during the years 1897 to 1900 was as follows per million gals.:

Scraping and removing sand	\$1.63
Washing sand	0.58
Replacing sand	0.58
Removing ice	0.42
Miscellaneous	0.10
Total	\$3.31
6% interest on filter plant (\$1,500 ÷ 680 million gals.)	2.30
Grand total	\$5.61

An average of 1,300 cu. yds. of sand was cleaned per year (there being about 15 scrapings a year), or nearly 2 cu. yds. cleaned per million gals. Hence by taking half of the above figures we have the cost of cleaning the sand per cubic yard, or a total of nearly \$1.40 per cu. yd. The scraping is done with shovels, the sand being removed in wheelbarrows. The sand washers are like those used at Albany (hoppers with ejectors). It is estimated that 12,000 gals. of water are used to wash each cubic yard of sand.

Cost of Filtering, Poughkeepsie.—Mr. Charles E. Fowler gives the following relative to the operation of the Poughkeepsie filter in 1900.

The sand is not scraped into heaps, but is shoveled direct into barrows. The back of a rake is used to level the surface after scraping. It takes 23 men 2 days of 8 hrs. each to scrape 1½ acres, wages \$1.50 a day, cost \$49 per acre. This includes wheeling to the corners of the filter bed, throwing up to top of coping and trimming back the pile.

The sand is stored and washed in October and replaced all at one time (16 days). Washing costs 32 cts. per cu. yd., and replacing costs 26 cts. per cu. yd., for a total of 910 cu. yds.

The total number of scrapings per year is not stated, but if there were 15 the cost was \$1.20 per cu. yd. for scraping, added to \$0.58 for washing and replacing; total \$1.78 per cu. yd. (Mr. Gregory gives the cost of scraping at \$1.30 per million gals. in 1900.)

The cost of ice removal varied from \$146 to \$613 a year, and averaged \$364 for four years prior to 1901, or \$273 per year per acre. To remove a 18-in. layer of ice in 1901 cost \$408 per acre of filtering area, wages being \$1.50 per 8-hr. day. The ice was sawed in parallel lines in one direction and broken by chisels in the other direction. The cakes were floated to a run at the side of the basin and pulled up by men with pikes. The water level was about 1 ft. below the top of the coping. The cakes were then pushed on nearly horizontal runs to the place of deposit, which costs about half of the total cost of ice removal. The cost of ice removal was 94 cts. per million gals. filtered that year, and there was only this one removal.

Cost of Washing Filter Sand, Poughkeepsie, N. Y.—Mr. Charles E. Fowler gives the following relative to sand washing at the Poughkeepsie filters in 1897. With two hoppers, and an upward water jet in each, the cost of washing the sand was 24 cts. per cu.

yd., laborers being paid 18 cts. per hr. The sand was delivered through a pipe to a tank 130 ft. away, and, after the remaining silt had flowed over the top of this tank, the sand was drawn off through a valve. Fifty cu. yds. of sand were washed per 10-hr. day, requiring 18 cu. ft. of water to each cu. ft. of sand, the water costing 3 cts. per cu. yd. of sand.

Cost Ice Removal From Filters.—Mr. John H. Gregory gives the following costs of snow and ice removal from filter beds per million gallons:

Lawrence (average 1896 to 1900).....	\$2.20
Poughkeepsie (average 1898 to 1900).....	0.48
Mt. Vernon (average 1897 to 1900).....	0.28

Estimated Cost of Filters and Filtering, Cincinnati, O. — Mr. George W. Fuller made the following comparative estimates of the cost of slow sand filtering and mechanical filtering for the city of Cincinnati, O., in 1899. A year's work with an experimental plant, of 100,000 gals. daily capacity, preceded the estimate. The plant designed for Cincinnati is to have a daily capacity of 80,000,000 gals. The estimated cost includes no allowance for cost of land, and covers only the expense from the time the water is discharged into the subsiding basins until it leaves the clear water reservoir, by gravity. The clear water reservoir is to hold 20,000,000 gals. The settling reservoirs are to hold 320,000,000 (48 hrs. subsidence or 96 hrs. capacity). The rate is to be 2,000,000 gals. per acre per day in the slow sand filter, and 125,000,000 in the mechanical filter. The following are the estimated first costs per million gallons daily capacity:

	—Filter Plant.—	
	Slow sand.	Mechanical.
Reservoirs	\$16,000	\$16,000
Pipe connections	500	500
Filter beds, chemical devices, piping, laboratory, etc.	16,667	7,500
Clear water reservoir	1,250	1,250
Coagulating and supplementary subsiding reservoir (20,000,000 gals.)		1,500
Total cost per million daily gals.	\$34,417	\$26,750
Interest and sinking fund (5% per year) per million gals.	\$4.72	\$3.67

The cost of operation of the slow sand filter plant is estimated thus:

	Per year.
1 superintendent	\$ 4,000
1 assistant superintendent	2,400
2 analysts, at \$1,500	3,000
3 assistants, clerks and janitor, at \$600	1,800
1 night watchman	720
3 reservoir attendants, at \$720	2,160
3 filter attendants, at \$720	2,160
1 storekeeper	720
6 chemical attendants for 6 mos. each year, at \$360	1,800
Extra labor	1,500
Total, 29,200 million gals., at \$0.72	\$20,860

The cost per million gallons is estimated thus:

Salaries (as above given).....	\$ 0.73
Ice removal, etc.....	0.30
Scraping 20 times a year, 325 man-hrs. per scraping, at 30 cts. per hr.....	1.19
Washing sand, 1.75 cu. yds., at 40 cts.....	0.70
Replacing sand, 1.75 cu. yds., at 20 cts.....	0.36
Sulphate of alumina, 0.95 gr. per gal., at 1.4 cts. per lb.....	1.90
Repairs, 0.5% cost per yr.....	0.47
Total operating expense.....	\$ 5.63
Capital charges (as above).....	4.72
Grand total	\$10.35

The estimated cost of salaries for a mechanical filter plant of the same capacity is as follows:

15 attendants for filters and chemical devices, at \$720.....	\$10,800
3 firemen, at \$720.....	2,160
1 mechanic	1,440
2 engineers, at \$1,440.....	4,320
1 superintendent	4,000
1 assistant superintendent	2,400
2 analysts	3,000
3 assistants, clerks, etc.....	1,800
1 night watchman	720
3 reservoir attendants	2,160
Extra labor	1,500

Total, 29,200 million gala., at \$1.17.....\$34,300

The estimated cost of operating the mechanical filter plant is as follows per million gallons:

Salaries (as above).....	\$1.17
Wash water, 5% of filtered water, at \$15 per million gala.....	0.75
Coal for power and light.....	0.15
Sulphate of alumina, 1.6 gra. per gal., at 1.4 cts. per lb.....	3.20
Repairs and replacements, machinery and chemical devices, 10% per yr. on \$2,500.....	0.69
Other repairs, 0.5% of first cost per yr.....	0.33

Total operating expense.....	\$6.29
Capital charges (as above).....	3.67

Grand total **\$9.96**

For the turbid water of the Ohio River at Cincinnati, Mr. Fuller recommended a mechanical filter plant.

Cost of Filtering and Ice Removal, Reading, Pa.—The water supply of Reading, Pa., is obtained by gravity systems and by pumping. Two of the gravity supplies—the Antietam supply and the Egelman supply—are filtered. Mr. Emil L. Neubling, Superintendent and Engineer of Waterworks, gives data for the fiscal year ending April 6, 1908.

Antietam Filters. The Antietam supply is obtained from a drainage area of 5.44 square miles. The storage reservoir capacity is 101,000,000 gallons. During the year this supply was treated with copper sulphate in order to remove the organism *anabaena* and to lighten the work of scraping at the Antietam filters. Two treat-

**Engineering-Contracting*, Oct. 28, 1908.

ments were given and the effect upon the operation of the filters was to reduce the total number of scrapings from 62 in the previous year to 48 during the past year.

The Antietam filters consist of three open sand beds, 108 x 144 ft. each, the capacity of each bed being 1,750,000 gallons per day. The filters were put into service on May 11, 1905. The total cost of operation and maintenance was \$3,909.46 or \$474.76 less than the previous year. Owing to the decreased efficiency of labor the cost of refilling the beds was 42 per cent higher per cubic yard than during the previous year. The cost of washing sand, however, was very materially reduced on account of placing the filter keeper in charge of the washing, thereby saving the services of an engineer. The cost of washing sand was reduced 11 cts. per cu. yd.

During February and March, 1908, 835 cu. yds. of ice was removed from the filter. The mean thickness of the ice was 4.35 ins., and the greatest average thickness was 53 ins. in February, when three beds were cleared. In March one bed was cleared, the average thickness of ice being 1.5 ins. The cost of removing the ice was as follows:

	Total.	Per cu. yd.
Labor, 228 hours.....	\$51.69	\$0.062
Superintendence	6.80	.007
Supplies90	.001
Total	\$59.39	\$0.070

It will be noticed common labor was paid about 21 cts. per hour.

The cost of scraping and wheeling out sand was as follows, 1,818 cu. yds. being removed:

	Total.	Per cu. yd.
Labor, 3,589½ hours.....	\$711.77	\$0.391
Superintendence	38.82	.021
Supplies	70.29	.039
Sulphate treatment	42.77	.024
Total	\$863.65	\$0.475

The cost of washing sand, 1,831 cu. yds. being washed, was as follows:

	Total.	Per cu. yd.
Labor, 1,539½ hours.....	\$282.38	\$0.154
Superintendence	30.43	.017
Supplies and repairs.....	794.49	.433
Total	\$1,107.30	\$0.604

The cost of refilling the beds was as follows, 1,921 cu. yds. of sand being used for refilling:

	Total.	Per cu. yd.
Labor, 4,838 hours	\$917.95	\$0.478
Superintendence	37.03	.020
Supplies	18.36	.010
Total	\$973.34	\$0.508

The total number of gallons of water filtered during the year was 1,182,557,923. The average quantity of water filtered between scrapings was 73,909,870 gallons or at the rate of 69,626,123 gallons per acre. The average quantity of water filtered per day was

3,231,032 gallons, or at the rate of 3,043,765 gallons per day per acre. The cost of filtering water per million gallons was as follows:

	Total	Per million gals.
Removing ice	\$ 59.39	\$0.050
Scraping and wheeling out sand.....	863.65	.730
Washing sand	1,107.30	.936
Refilling beds	973.34	.823
Care of grounds.....	513.86	.434
Analyses	37.38	.030
Watching	150.09	.130
Operation and general maintenance.....	204.45	.180
Total	\$3,909.46	\$3.313

The cost of filtering water per million gallons, excluding analyses and care of grounds was \$2.84.

Engelman Filters.—The Engelman supply has a drainage area of 0.6 square miles and a storage reservoir capacity of 6,900,000 gallons. The Engelman filter consists of two open sand beds, 40 x 55 ft. each; the capacity of each bed is 250,000 gals. per day. The filters were put into service on July 11, 1903.

On account of not washing sand and refilling beds during the year, the cost of operation was considerably less than for the previous year. The unit cost of scraping and wheeling out sand was 3 cts. per cubic yard more than for the previous year, and the cost of ice removal 2 cts. per cubic yard less.

A total of 147 cu. yds. of ice was removed from these filters, the mean thickness of the ice being 3.6 ins. The greatest thickness was 6.2 ins. in February, 1906. The cost of removing ice was 10 cts. per cubic yard, the work requiring 67 hours labor at a total cost of \$11.05.

The cost of scraping and wheeling out sand was as follows:

	Total.
Labor, 450½ hours	\$82.83
Superintendence	1.70
Total	\$84.52

A total of 122 cu. yds. of sand was removed, the cost per cubic yard being \$0.69.

The total number of gallons of water filtered during the year was 79,784,796. The average quantity of water filtered between scrapings was 4,693,234 gallons, or at the rate of 43,675.541 gallons per acre. The average quantity of water filtered per day was 217,992 gallons, or at the rate of 2,260,888 gallons per acre per day.

The cost of filtering the water per million gallons was as follows:

	Total.	Per million gals.
Removing ice	\$ 14.05	\$0.177
Scraping and wheeling out sand.....	83.82	1.038
Operation and general maintenance.....	109.56	1.373
Analyses	31.10	.391
Care of grounds.....	45.25	.567
Total	\$284.48	\$3.546

The cost of filtering water per million gallons, exclusive of cost of analyses and care of grounds was \$2.61.

Cost of Filtering, Brooklyn, N. Y.—Mr. I. M. de Varona gives the following data relative to 4 filter plants in Brooklyn, 2 mechanical and 2 slow sand filters. The mechanical filter plant at Balseleys is of the gravity type and has a normal capacity of 5,000,000 gals. per day. It has circular wooden tanks; air is used to agitate the sand during washing.

The mechanical filter plant at Springfield is similar to that at Balseleys, but its normal capacity is only 3,000,000 gals. per day. For the 12 mos. of 1905 the cost of operating these plants was as follows:

	Balseleys.	Springfield.
Inspection	\$ 484.80	\$ 462.79
Operation	4,714.08	3,182.91
Laboratory	443.68	409.23
Repairs	507.78	232.53
Interest and sinking fund.....	3,218.61	2,366.28
Total	\$9,363.98	\$6,653.74
Million gals. filtered.....	1,435.5	694.6
Cost per million gals.....	\$6.53	\$9.58

The Forest Stream slow sand filter plant has two sand beds having a daily capacity of 6,000,000 gals., the area of the bottom of the beds being 2 acres. The beds have no covering and have no impervious bottom, nor side walls. Collecting pipes are laid below the ground water level, so there is practically no loss of water by this form of construction. The bed is underlaid by gravel, and the 6-in. underdrains are 12 1/4 ft. c. to c.

The Hempstead slow sand filter plant is similar to the Forest Stream plant, but the two beds have an area of only 0.9 acre and a daily capacity of 3,000,000 gals.

The cost of operating these plants during 1905 was as follows:

	Forest Stream.	Hempstead.
Inspection	\$ 348.91	\$ 214.76
Laboratory	335.12	419.26
Labor and materials.....	710.00	239.47
Interest only	1,058.40	330.00
Total	\$2,452.43	\$1,203.49
Million gals. filtered.....	1,075.3	416.8
Cost per million gals.....	\$2.28	\$2.89

At Hempstead a new method of cleaning the beds was used, which consists in washing the beds instead of scraping them. The cost of this cleaning by washing was 40 cts. per million gals. instead of \$1 by scraping. The beds are divided into channels 20 ft. wide, by means of boards set vertically, extending 8 ins. above the surface and 6 ins. below the bottom of the sand. The boards are laid to within 15 ft. of the ends of the beds, and boards can be placed across the ends of the channel ways so as to cause a flow of water through any desired channel way. When the bed is ready to be cleaned it is drained so that only 4 or 5 ins. of water are left on the bed, and waste pipe gate is opened; then a gate on the pipe

between the two beds is opened to allow the raw water in the adjoining bed to flow into the bed to be cleaned. The velocity of the water is regulated so that it will not quite carry the sand. Men with rakes stir up the surface of the bed, so that the dirt is carried away in suspension. The men work from the head of the bed toward the outlet. When one channel is cleaned, stop planks are placed across its end, and a second channel is cleaned. One bed (0.45 acres) is cleaned by 8 men in 4 hrs., using 250,000 gals. of water. The quantity of water filtered between cleanings is about 25% less when the beds are washed instead of scraped.

At the Forest Stream plant, 60,000,000 gals. are filtered between scrapings.

Output of Sand Washers.*—In a sand filtration plant the sand is, in a way, the most important part of the filters. It is important, therefore, to secure the best sand that can be reasonably obtained. The following method of securing and preparing filter sand was used in the construction of the water filtration plant of Washington, D. C., and was described by Mr. Allen Hazen and Mr. E. D. Hardy, *Trans. Am. Soc. C. E.*, 1906.

The contractor furnished sand from a bank at Laurel, Md., on the main line of the Baltimore & Ohio R. R., half way to Baltimore. This bank was probably of tertiary origin, and consisted of layers of clay and sand. The sand in the sand layers was of good quality, except that more or less clay was distributed through it. The layers of clay ranged in thickness from a few inches to several feet, and the mixture was such that it was not possible to take the sand without the clay.

The method of securing and preparing filter sand of the requisite cleanliness and of the quality specified was as follows: The sand was excavated from the bank with steam shovels, taking the mixed material, to a depth often reaching 20 ft. The material obtained in this way consisted mostly of sand, but large and small lumps of clay were always mixed with it, and the top soil was not separated. The proportion of the material which could not form part of the filter sand was rather large. The sand was loaded on cars, which carried it on temporary tracks to the screening and washing plant built close to the main line of the Baltimore & Ohio R. R.

The material was first dumped from the cars through a coarse grating which separated many of the largest lumps of clay. It then passed through a revolving screen, with holes about 2 ins. in diameter, which removed further quantities of clay in lumps. It was then taken by a link-belt elevator to the top of a timber trestle, and discharged into a revolving screen, with round holes having a size of separation of about 4 mm. Water jets played upon this screen and facilitated the passage of sand through it, while much fine gravel and some additional lumps of clay were removed. The specifications provided that the sand must be free from particles more than 5 mm. in diameter, and the screen secured this result. The material passing through the screen consisted of the sand, to-

**Engineering-Contracting*, Feb. 20, 1907

gether with a large quantity of clay, partly pulverized and partly in lumps, all carried by a considerable quantity of water. The mixture then passed to a series of pug-mills. The revolving arms in these broke up and pulverized the remaining clay lumps. This treatment was necessary for a material containing clay in lumps, but would be unnecessary for sand not containing such material.

The pug-mills incidentally served to separate a portion of the clay from the sand, for an excess of water entered them, and extremely dirty water was constantly wasting over their tops, while the sand was drawn out from points near the bottoms in much the same way as it was subsequently drawn from the sand washers.

The mixture of sand, clay and water leaving the pug-mills next passed to the washers. These washers, Fig. 24, consisted of three long, narrow boxes with bottoms having slopes of 1 in 6 to the point of discharge. The boxes were 16 ft. long, 24 in. wide and 18 in. deep at the upper end. There were four pipes, perforated for their entire length, in the bottom of each box, the holes opening directly downward. Water was forced through these pipes at a rate of about 1 cu. ft. per min. per sq. ft. of box area. This water went upward and overflowed into a trough running lengthwise of the box at the top. The mixed materials entered this box at the upper end, flowed through it, and were discharged at the lower end from the bottom. There were, therefore, two movements in each box; first, a movement of wash-water upward from the bottom of the box to the top and out through the waste overflow; and second, a forward movement of sand from one end of the box to the other. The upward movement of water, starting from the whole area of the bottom and overflowing from most of the area of the top, kept the sand in a semi-suspended state and practically in the condition of quicksand.

Under these conditions the larger particles of sand rapidly sank to the bottom while the finer particles were carried to the top. The sand at the bottom was in contact with the clean water as it first entered the box, while, by controlling the quantities of sand let in and drawn out, the finer particles could be forced to the top and out through the waste overflow to any desired extent. The level of the sand in the box was usually carried not more than about 6 in. below the surface of the water.

As the sand in the box was in the state of quicksand, it was possible to draw it out, through a gate placed just above the bottom at the lower end of the washer, in the form of a fluid containing very little water. Generally, 10 parts of the mixture drawn from the outlet contained 9 parts of solid sand. The mixture fell into a large hopper, from which a gate allowed it to flow from time to time into cars on a side-track below, often without further separation of water, except as it gradually drained out through the cracks in the hopper and in the bottoms of the cars.

In general, it was found that 1 cu. yd. of sand per hour could be washed for each square foot of box area, and sometimes a larger quantity was passed.

SECTIONAL ELEVATION

Fig. 24—Sand Washer.

A washing box of this character was first designed by one of the writers for use in preparing filter sand at Yonkers, N. Y. The same type of box was used in preparing all the sand placed in the filters at Providence, R. I., and has also been used elsewhere.

The separation of the clay from the sand in such large quantities and so cheaply was an achievement which would hardly have been regarded as possible at the time the contract for filter sand was made, and the use of this process cheapened the sand washing very greatly, the actual cost to the contractor being far below the contract price.

Although exact figures are not at hand, it appears that the volume of water used in washing the sand was not more than five or six times that of the sand. The wash-water was obtained from a small creek nearby, and was pumped through a 10-in. pipe. After rains the water in this creek was quite turbid, but this turbidity did not interfere materially with the washing, or with the quality of the sand produced.

In a working day of 10 hours more than 900 cu. yds. of filter sand were frequently produced, and, had it been possible to handle the sand at the filters more rapidly, the plant could have worked at night, with a greatly increased output.

The specifications provided that the filtering sand should be entirely free from clay. The specification had proved sufficient in securing sand from river deposits and from sand banks of glacial origin. It did not prove satisfactory in the case of this sand, as the raw material contained large quantities of clay. The clay stuck to the particles of sand on drying, and the ordinary mechanical analysis, by sifting the material in a dry state, was inadequate to show its presence or amount.

It becomes apparent at once that a method of measuring the amount of clay in the sand must be found and used, and definite limits set to the amount of clay that could be present, which should be substantially equivalent to the requirements of the specifications.

The method adopted of determining the amount of clay was as follows: A weighed quantity of sand, usually 25 g. but less if there was considerable clay in it, and more if there was but little—was agitated for some minutes with several times its volume of water. The sand for this purpose was taken directly from the washers and was not dried, as drying increased the difficulty of getting the clay in suspension. If the sand had dried before testing, it was necessary to keep it moist and agitate it for some time to get all the clay loose. When this was accomplished the mixture was made up to a volume of 1 liter in a graduated glass. This was allowed to stand for 1 min. The turbidity of the supernatant fluid was then taken by observing the depth below the surface that a platinum wire could be seen, by the method of the U. S. Geological Survey.

These observations were taken in the graduated glass for convenience. This was not strictly in accordance with the official instructions, but it was more convenient, and the comparative re-

sults were good. Jackson's turbidimeter was used with good results for night work, but the rod was preferred by the inspectors when it could be used. The turbidity of the water thus found was multiplied by the ratio of the volume of the mixture to the weight of sand taken. That is to say, for the quantities above stated it was multiplied by 40. The figures thus represent approximately the turbidity in the sand in parts per million by weight. One part of clay by weight actually produces about two parts of turbidity, because the particles of clay are much finer than the particles of standard turbidity, but this matter is overlooked, and the results are expressed as standard turbidity in parts per million. To get the actual weight of the clay, therefore, the figures should be divided by two.

It was decided after study that a reasonable interpretation of the specification, expressed in terms of turbidity, was represented by 4,000 parts per million, and this limit was rigidly insisted upon. Generally, the sand contained less than 3,000 and frequently less than 2,000 turbidity, the last figure corresponding to less than 0.1 per cent of actual clay by weight in the sand as delivered. That this result could be regularly secured from a bank where a considerable percentage of the total material was clay is, the writers think, a very remarkable result, indicating both an excellent apparatus and most efficient management, on the part of the contractor, and by the sand inspectors.

Part of the sand-washing plant was duplicated. This was done before the full capacity of the part first built was realized. It was intended to insure against delay in case of accident and to allow an increased output, but the first part did so well that the second part was used hardly enough to test it.

The sand was taken in cars to an elevated siding near the filters, and dumped into hoppers. These hoppers were provided with sand-gates, and carts were driven underneath and loaded from them. These carts were taken over the roofs of the filters, and the sand was dumped through the manholes. Chutes were arranged under the manholes, upon which the sand fell. This broke the force of the fall which, otherwise, might have compacted the sand to an undesirable extent, and also threw it to a considerable distance horizontally. The chutes were revolved, and in this way most of the filter sand was placed directly where it was wanted without further handling. It was necessary to place only a small part of it with shovels. This method of placing the sand in the filters is so simple and cheap that it has been adopted for regular use in replacing the washed sand in the filters.

The sand settled, on an average, about 5 per cent when it was wet and the filters were placed in service. The average depth of the sand in the filters after settling was 38 ins., but different filters were filled to different depths, so that when sand is replaced from the washers in the filters it will go first to the filters having initially the least sand, and a regular regime is thus established from the start.

Cost of Filter, Lambertville, N. J.—Mr. Churchill Hungerford gives the following relative to a small slow sand filter at Lambertville, N. J., built in 1878. There are two filter beds, each 60 x 100 ft., giving a total of 0.28 acre, and the cost was \$5,600, or at the rate of \$20,000 per acre. They were built in clay and not lined with concrete, but the side slopes and bottom were riprapped with stone. A puddle trench 4 ft. wide runs beneath all the embankments, averaging about 10 ft. deep. The basins are 9 ft. deep. A 12-in. vitrified pipe runs the entire length of each basin, on one side, and is fed by 4-in. vitrified pipes spaced 2 ft. c. to c. Gravel was placed around and over the pipes, and a layer of sand $2\frac{1}{2}$ ft. thick. The filter delivers 225,000 gals. per day, but has a much greater capacity.

Cost of Reinforced Concrete Roof for Filter, Indianapolis.—Mr. William Curtis Mabey gives the following data relative to the cost of covering 48 acres of filter beds with a reinforced concrete roof resting on steel beams and cast-iron posts, built in 1905, for the Indianapolis Water Co., by day labor.

The filter beds had been in operation for a year or more, but ice and algae had caused so much trouble that it was decided to roof them, disturbing the filter sand as little as possible. The roofing cost $35\frac{1}{2}$ cts. per sq. ft., including 2 ft. of cinders and a concrete parapet wall all around the roof to hold the cinders. The concrete for the roof was mixed 1:2:4, and amounts to 0.017 cu. yd. per sq. ft. The roof is a continuous slab 3 ins. thick, reinforced with $\frac{1}{4}$ -in. corrugated rods spaced 3 ins. c. to c. in parallel lines, and with cross rods of the same size spaced similarly. The roof slab is supported by concrete girders, 8 ins. wide, with a depth of 10 ins. below the roof slab, and spaced 6 ft. 9 ins. c. to c. Each girder is designed as a continuous beam, reinforced with four $\frac{1}{4}$ -in. corrugated rods, each bar being so bent that for three-quarters of its length it is near the bottom of the beam, and then passes along the top of the beam and over the supporting I-beam for about a quarter span; hence each bar has a length of about $1\frac{1}{4}$ times the length of the beam. These reinforced concrete beams are supported by steel I-beams. The I-beams are 18-in. (55 lb.), spaced $19\frac{1}{2}$ ft. c. to c., and are embedded in concrete 10 ins. thick. The I-beams are spliced at the quarter point of the span. The I-beams are supported by 7-in. cast-iron columns spaced 20 ft. c. to c., filled with concrete. The columns rest on concrete pedestals, the top of which is 6 ins. above the surface of the filter sand. The excavation for these columns was accomplished by the aid of light steel cylinders that were sunk through 4 ft. of filter material, and then filled with concrete. The cast-iron columns are $11\frac{1}{4}$ to 12 ft. long. Being only 7 ins. diam. and spaced 20 ft. apart, there is a gain of more than 1 per cent in the effective filtering area under the roof, as compared with the ordinary brick columns 20 ins. square and spaced 14 ft. c. to c.

The use of cinders instead of earth effects a decided saving in the amount of material required for the roof, and the cinders, in

this case, cost no more than earth. The roof was designed to support the cinders and such water as they would hold. A factor of safety of 3 was adopted for the roof reinforcement, based upon 50,000 lbs. per sq. in. elastic limit of steel, and using 1 per cent reinforcement.

The iron, steel and concrete were handled by a movable cableway spanning the filter beds.

The centering was supported from the steel I-beams, by U-bolts, and was left in place 10 to 14 days, or until the concrete would ring under a hammer when struck lightly.

Cost of Seven Mechanical Filters. Table XIV gives the first cost of 7 mechanical filter plants of the Jewell type:

TABLE XIV.

Locality.	When finished.	Capacity per day, gals.	Cost without buildings or clear reservoir.	Cost with buildings and clear reservoir.
Terre Haute, Ind....	1891	4,000,000	\$20,000	\$45,000 (1)
Chattanooga, Tenn....	1893	3,000,000	30,000	32,000 (2)
Burlington, Ia.....	1894	3,500,000	38,000	76,000 (3)
Ottumwa, Ia.....	1895	2,000,000	18,500	21,500 (4)
Danville, Pa.....	1895	1,000,000	6,000	14,000 (5)
Lexington, Ky.....	1895	2,000,000	27,000 (6)
Cedar Rapids, Ia....	1896	4,000,000	32,000	47,000 (7)
Total		19,500,000		\$261,500

Notes.—(1) The buildings cost \$5,000 and the clear water reservoir cost \$10,000.

(2) There is no clear water reservoir.

(3) The clear water reservoir holds 500,000 gals.

(4) The settling tanks are combined with the filtering tanks, being below the filtering material. The 6 filters are housed in a brick building, 41 x 95 ft.

(5) Extra pumps, \$1,000; clear water reservoir of 90,000 gals. (roofed), \$7,000. It is not clear whether a building is included in the \$14,000.

(6) The clear water reservoir holds 330,000 gals.

(7) Brick building, 40 x 140 ft., clear water reservoir beneath. The cost includes two 3,000,000-gal. low service pumps.

Cost of Mechanical Filter, Danville, Ill.—A mechanical filter plant built at Danville, Ill., in 1903, cost \$75,000 for buildings, filters, coagulating basins, clear water reservoir, and the operating machinery. The capacity of the plant is 6,000,000 gals. per day. The filter beds have a capacity of 125,000,000 gals. per acre per day. The coagulant is lime and sulphate of iron specified not to cost more than \$1.10 per million gallons when the water has "average turbidity."

Cost of Mechanical Filter and of Filtering, Norfolk, Va.—Mr. Edmund B. Weston gives the following relative to a mechanical filter plant built in 1899 at Norfolk, Va. The plant has a capacity of 8,000,000 gals. per day. There are 16 filters, each 15 ft. in diameter. At a rate of 127,000,000 gals. per acre per day, each filter has a daily capacity of 500,000 gals. The cost of the filter plant, exclusive of a 5,000,000-gal. subsiding reservoir and a 1,000,000-gal. clear water reservoir, was as follows:

Filter buildings and foundations.....	\$ 23,342
Filters and auxiliaries	74,083
Pump for supplying filters.	1,600
Electric light equipment, etc	698
Total	\$ 99,808
Work upon subsiding reservoir including drainage pump..	4,690
Total	\$104,498

The subsiding reservoir was already in existence, being an old reservoir.

The cost of operation during the month of March, 1900, which was typical, was as follows, per million gallons:

Labor	\$1.13
Coal at \$3 per ton.....	0.86
Clearing subsiding reservoir.....	0.08
1.95 grains of sulphate of alumina per gal., at 1.2 cts. per lb...	3.40
Total	\$5.47
Additional labor if pumping station were not adjacent to filter building	0.33
Total	\$5.80

This does not include interest, depreciation and repairs, which it is safe to say, would amount to at least \$3 per million gallons, if the cost of the subsiding reservoir and clear water reservoir are included.

Cost of Mechanical Filter and of Filtering, Wilkes-Barre, Pa.—
A mechanical filter plant (of the Jewell type) was built in 1895 at Wilkes-Barre, Pa. The cost was \$122,400, including a brick building having 11,200 ft. floor area. There are 20 filter tanks, having a combined area of 2,260 sq. ft., and a daily capacity of 10,000,000 gals. There are two 50-hp. boilers, a 10 x 10 x 12-in. pump for raising filtered water for washing the filters, a 15-hp. engine for driving the sand agitators, a 6 x 10 x 12-in. air compressor for agitating the solution in the coagulant tank, and a dynamo for lighting. Sulphate of alumina is used as a coagulant, the maximum being $\frac{1}{2}$ gr. per gal.

The cost of operation per day was:

2 engineers, at \$2.15.....	\$ 4.30
2 foremen, at \$1.75.....	3.50
2 laborers, at \$1.50.....	3.00
Coal	0.78
Hauling coal	0.75
250 lbs. alum (for 7,000,000 gals.), at 1.75 cts.....	3.82
Total, 7,000,000 gals, at \$2.31.....	\$16.16

In 1896 the labor and fuel cost of filtering 9,000,000 gals. per day was reduced to the following daily cost.

2 engineers, at \$2.15.....	\$4.30
2 washers, at \$1.62½.....	3.25
Fuel	1.30
Oil, waste, etc.....	0.11
Total	\$8.96

This is \$1 per million gals. exclusive of the coagulant and of interest and depreciation of plant. The first cost of the plant was \$12,200 per million gals. of daily capacity.

Cost of Mechanical Filter, Asbury Park, N. J.—A mechanical filter (Continental) was built in 1894 at Asbury Park, N. J., for removing the iron from artesian well water. Its capacity is 2,000,000 gals. per day, and its cost was \$20,000, not including a brick building 45 x 45 ft. (2,025 sq. ft.), estimated to cost \$1,500. This does not include a 12-ft. standpipe 125 ft. high, which receives the clear water. About 10 per cent of the total pumpage is used for washing the filters.

Cost of Mechanical Filter and Filtering, Elmira, N. Y.—Mr. J. M. Divens states that the mechanical filter plant at Elmira, N. Y., has a capacity of 6 million gals. daily, and its cost was \$66,000, including building. The cost of filtering, \$2.80 per million gals., to which \$0.70 should be added for interest and depreciation; total, \$3.50.

Cost of Water Softening.—Mr. W. B. Gerrish gives the following relative to a water softening plant built in 1905 at Oberlin, O. The plant cost \$12,000, and treats 165,000 gals. per day. The water is softened by the use of lime and soda. From 6 to 17 grains of lime and 2 to 6 grains of soda are used per gallon. The two (7 x 7 ft.) pressure filters are washed twice a week. The cost of treatment averages as follows per million gallons:

Chemicals	\$10
Labor, interest and depreciation.....	15
Total	\$25

Cost of Concrete, Asphalt and Brick Reservoir Lining.—Mr. Arthur L. Adams gives the following data on the Astoria (Ore.) City Water Works: The reservoir bottom is lined with 6 ins. of concrete (laid with expansion joints), $\frac{3}{4}$ -in. of cement mortar, one coat of liquid asphalt, and one harder asphalt coat. The lining of the slopes is the same except that a layer of brick laid flat, after dipping each brick in hot asphalt, was laid on the concrete. The bricks were laid on an asphalt coating and given a final asphalt coat. The actual cost per sq. ft. was:

Slope.	Per sq. ft.	Bottom.	Per sq. ft.
6-in. concrete.....	\$0.1187	6-in. concrete	\$0.1031
1st coat asphalt.....	0.0100	Cement mortar finish...	0.0113
Brick in asphalt.....	0.0889	1st coat asphalt	0.0077
2d coat asphalt	0.0131	2d coat asphalt.....	0.0082
Chinking crevices with asphalt*	0.0030		
Ironing	0.0036		
Total	\$0.2372	Total	\$0.1303

*These crevices developed near the top of the slope, due to sliding of the brick slope.

The detailed cost of this lining work was as follows:

The concrete was composed of basalt rock, quarried and crushed

near the work, of river gravel, sand and imported Portland cement. One cubic yard of concrete contained 0.9 cu. yd. stone, 0.5 cu. yd. gravel, 0.1 cu. yd. sand and 1 bbl. cement. There were 663 cu. yds. of concrete on slopes and 678 cu. yds. on the bottom. The work was well managed, each man averaging 1.84 cu. yds. per 10-hr. day, mixed and placed on the slopes, and 2.35 cu. yds. on the bottom. The men were Italians. The rock was quarried and crushed and delivered at the work (800 ft. haul) for 95 cts. per cu. yd. Sand and gravel were bought at 86½ cts. per cu. yd., and cement at \$2.45 per bbl. All mixing was done by hand. There were three gangs of mixers, 6 men in a gang, supplied with materials by 9 wheelbarrow men (5 on rock, 3 on gravel and sand and 1 on cement). The 18 mixers placed the concrete for 6 men to rake and ram. Beside this force of 33 men, there were: 1 helper at the cement, 1 man tending water, 1 man sprinkling concrete already laid, 1 water-boy and 1 foreman. The gravel, sand and cement were mixed dry, then mixed wet, and stone added; the concrete was then turned three times, and once more when deposited. On the slopes a rough finishing coat of mortar was applied by taking a little mortar from the next batch. The concrete was mixed with very little water. By raking the coarse rock down the slopes and by using a straight edge before ramming, even slopes were secured.

On the bottom the ¾-in. mortar (1:2) coat was applied by two finishers using smoothing trowels, and they were served by 4 men mixing and carrying the mortar.

On the slopes the concrete was placed in sheets 16 ft. wide from top to bottom; and on the bottom it was laid in squares, 20 ft. on a side; 2 x 6-in. planks being used to hold the free sides of the concrete. When a new square was laid adjoining an old square, the 2 x 6 pieces were removed, and replaced by a piece of ½ x 4-in. weather boarding. Two weeks later these ½-in. strips were removed so that the grooves could be run full of asphalt. The ½-in. strips should be beveled and laid with the wide edge up, or they will be removed with difficulty. The labor cost of concreting was \$1.07 per cu. yd. on the slopes and 67 cts. on the bottom, wages being 16 cts. an hour.

Two grades of Alcatraz asphalt were used: the L and the XXX, or paving brand. The L grade is a natural liquid asphalt, and the XXX grade is the product of refining the natural rock asphalt with about 20 per cent of the liquid as a flux; they are sold in barrels holding 400 lbs. No asphalt was placed on the concrete until it had been in place two weeks and was dry on the surface. On the bottom of the reservoir the first coat applied was the L grade, the second coat was the XXX grade. On the slopes none of the L grade was used, because of its tendency to creep, moreover the harder asphalt when at the proper temperature runs readily and fills all crevices. The only advantage of the L grade is that it will adhere to a damp surface where the XXX will not.

For best results all work should be done in the dry summer months. All dust must be carefully swept off the concrete as it prevents bonding with the asphalt. The asphalt applied with mops made of twine, was delivered in sheet-iron buckets by attendants who carried it from two melting kettles holding 3,000 lbs. each.

The bricks used on the slopes were half vitrified and half common, due to inability to get the full number of vitrified bricks. They were submerged in a bucket of hot asphalt and placed on the slope with iron tongs; a common laborer, after a little practice, readily averaged 2,300 bricks laid in 10 hrs. A push joint was made. To secure close joints and consequent economy in asphalt, the asphalt must be kept hot enough to run like water.

The asphalt finishing coat followed the brick laying as closely as possible, to avoid delays due to rain-water standing in open joints. The slope was ironed with hot irons to improve the appearance. Overheating of the irons is apt to injure the asphalt. During hot weather the brick slid on the slope somewhat by closing up thick joints laid in colder weather; but all motion ceased in a few weeks. The advantage of asphalt lies in retarding the passage of water through brick or concrete; it does not exclude water, for an asphalt coated brick submerged in water will eventually absorb as much water as an uncoated brick.

Cost of Lining a Reservoir With Asphalt.—In Trans. Am. Soc. C. E., 1892, Vol. 27, p. 629, Mr. James D. Schuyler discusses the use of California asphalt for lining two reservoirs of the Citizens' Water Co., at Denver, Colo.

The earth slopes of a reservoir were first sprinkled and rolled with a 5-ton slope roller, operated by a hoisting engine mounted on rails on top of the embankment. Slopes were $1\frac{1}{2}$ to 1, and depth of water was 20 ft. Beginning at the bottom the asphalt was laid on the earth slopes in horizontal strips 10 ft. wide, $1\frac{1}{2}$ in. thick, spread with hot rakes, tamped with hot tampons, and ironed with hot smoothing irons. Asphalt was hauled $2\frac{1}{2}$ miles and delivered at a temperature of 250° . While the asphalt sheet was still warm, anchor spikes, of $\frac{1}{2} \times 1$ -in. strap iron 8 in. long, were driven through the asphalt into the bank in rows 1 ft. apart. Every other row was driven flush, the alternate rows being temporarily left projecting $1\frac{1}{2}$ in., to serve as a rest for 2×4 -in. strips of lumber, forming steps for the workmen. When the finishing coat came to be applied these spikes were driven in flush.

The bottom was coated with asphalt 1 in. thick, and after tamping was rolled with a cold 5-ton steam roller. The finishing coat of refined Trinidad asphalt, fluxed with residuum oil, was poured on hot from buckets and ironed with smoothers heated to cherry red. When first applied the irons produced a yellow smoke, and had to be moved rapidly, but thus only could a good bond be secured with the first coat.

The cost of asphaltting a reservoir having a bottom area of 87,300 sq. ft. and a side-slope area of 65,300 sq. ft., or a total of 152,600 sq. ft., was as follows:

1,304 tons, 20% asphalt mastic, 80% sand, at \$12.....	\$15,648.00
15 tons, 15% asphalt mastic, 85% sand, at \$10.....	580.00
86 21 tons liquid asphalt fluxed with oil, at \$40.....	3,448.40
Fuel for heating irons and for steam roller.....	276.02
Lights	36.00
Tools	179.75
Pegirons, material and labor of cutting and dipping in asphalt	650.00
Labor	1,921.50
Use of roller 6 days.....	60.00

Total for 152,600 sq. ft., at 14.94 cts. per sq. ft....\$22,799.67

Mr. Schuyler informs me that, as nearly as he can remember, men were paid \$1.75 per 10-hr. day, although possibly the rate was \$2 a day.

The second reservoir was lined in a manner similar to the first, just described. The total area of bottom and slopes was 143,670 sq. ft., which required 1,156 short tons of the asphalt and sand mixture for the first coat; and as this mixture weighed 127 lbs. per cu. ft. after compression, the average thickness was 1.53 in., requiring 16 lbs. per sq. ft. The finishing coat was $\frac{1}{2}$ to $\frac{3}{4}$ -in. thick, and required 1.24 lbs. of asphalt per sq. ft. The cost of lining this reservoir was as follows:

	Cts. per sq. ft.
Materials for first coat.....	8.98
Materials for second coat.....	2.48
Labor, fuel, spikes, etc.....	1.99
Total cost of both coats.....	13.45

In preparing the mastic for the first coat 78% of La Patera asphalt and 22% of Las Conchas flux were boiled together in open kettles for 12 hrs., at 250° to 300°, with frequent stirring. Then 20% (by weight) of this mastic was mixed with 80% of sand heated to 300°, a cylinder with strong paddles being used for the mixing, which took about 2 mins. The charge was dumped into a cart, hauled to the reservoir and dumped upon a wooden platform, and thence taken in hot scoops, spread and raked. Hot rollers were then used, and they were superior to tamping and ironing. These rollers were made from sections of cast iron pipe, turned smooth on the outside, and fitted inside with a hanging basket in which a fire was maintained. For the bottom rolling a 30-in. pipe was used; for the slopes a 14-in. pipe, pulled with a $\frac{3}{4}$ -in. wire cable passing over a pulley at the top of the slope, was used.

Asphalt as a reservoir lining possesses several advantages: It will not crack even when there is considerable settlement of the embankment. If cracks do occur it is easily patched, the new material uniting perfectly with the old.

To prevent earth from crumbling and rolling down upon the partly completed asphalt, it is often wise to plaster the earth with a mortar of sand, cement and lime to a thickness of nearly 1 in., which will cost about $\frac{1}{2}$ ct. per sq. ft. On this should be spread a thin coat of liquid asphalt as a binder, which would have the additional advantage of protecting the asphalt from ground water. To prevent accumulated ground water from forcing off the asphalt lining, when the water in a reservoir is drawn down, it is often necessary to provide broken stone drains back of the lining. These drains may be led to a receiving well connected with the reservoir by pipes provided with valves opening automatically into the reservoir.

Ice, 18 ins. thick, has been frozen fast to the asphalt lining all around, and the water lowered and raised again 3 or 4 ft. without damaging the lining in the least.

I am informed (September, 1904) by Mr. Geo. S. Prince, Asst. Ch. Engr. the Denver Union Water Co., that this asphalt lining has not been durable. "It has run considerably on the slopes and this has resulted in the cracking and disintegrating of the asphalt so that considerable expense has been involved in keeping it in anything like serviceable condition and we would not consider using it again in this connection, preferring rather to employ concrete linings."

Cost of Lining a Reservoir With Concrete.—Mr. G. L. Christian gives the following: In laying 3,000 cu. yds. of 1:3:6 concrete, 6 ins. deep, over the bottom of a reservoir, the wages paid were: Foreman, \$2.50; laborers, \$1.35, and teams, \$4 a day. The cost of blasting the rock is not included, but the cost of loading, hauling and crushing is included:

	Per cu. yd.
Sand	\$.37
Natural cement	1.10
Loading and hauling stone to crusher.....	.25
Labor at crusher, at \$1.35 a day.....	.20
Rent of crusher.....	.01
Coal for crusher05
Hauling stone from crusher.....	.15
Foreman of concrete gang.....	.05
Laborers concreting, at \$1.35.....	.50
Teams concreting, at \$4.....	.08
Total	\$2.76
9% for supt., timekeeper, office help, etc....	.24
Total	\$3.00

The concrete was mixed very wet.

Cost of a Concrete Reservoir Floor at Pittsburg, Pa.—Mr. Emile Low gives the following data:

The floor of the Highland Ave. Reservoir at Pittsburg, Pa., was covered in 1884 to a depth of 5 ins. with concrete, laid on a clay puddle foundation. The concrete mortar was made of 1 bbl. natural cement to 2 bbls. sand, mixed to a thin grout in wooden boxes standing on legs. Five barrels of stone (standstone) were spread on a platform of 2-in. plank, 10 x 16 ft., and the grout was poured over it, the whole mass being then turned over three times with shovels, then deposited to the depth of 6 ins. and rammed. The stone was quarried and hauled 20 miles by rail, then unloaded into small cars and hauled $\frac{1}{2}$ mile to the reservoir. The sand was obtained in the reservoir limits, and cost merely the work of excavation, or $1\frac{1}{4}$ cts. per bushel.

The following was the cost of two days' work:

27 laborers, 2 days, at \$1.25.....	\$72.90
1 foreman, 2 days, at \$2.50.....	5.00

Total, 101 cu. yds., at 77 cts.....\$77.90

During one month the labor cost was:

	Total cost.
42 days, laborers at \$1.35.....	\$866.70
17 days, water-boy, at 60 cts.....	10.20
22 days, foreman, at \$2.50.....	55.00

Total, 1,302 cu. yds., at 71½ cts.....\$931.90

During another month 1,425 cu. yds. were laid at 95 cts. per cu. yd., wages being \$1.25 a day.

The average cost of the 7,680 cu. yds. of 1:2:5 concrete was:

	Per cu. yd.
Quarrying stone	\$.45
Transporting stone50
Breaking stone (2¼-in. ring).....	.35
1½ bbl. natural cement.....	1.80
8 bu. sand.....	.10
Water05
Labor (wages \$1.25 a day), mixing and laying.....	.75
Incidentals05

Total**\$4.05**

The contract price was \$6 per cu. yd.

Cost of Reservoir, Forbes Hill, Mass.—Mr. C. M. Saville gives the following relative to a small reservoir (Forbes Hill) at Quincy, Mass., holding 5,000,000 gals. The bottom is 100 x 280 ft., and the sides slope 1 to 1½. The lining is concrete. The excavated earth was used to build the banks, which are 17 ft. wide on top.

The cost, at contract prices, was as follows:

30,100 cu. yds. earth excavation, at \$0.38.....	\$11,438
Rock excavation, at \$2.50.....	52
2,337 cu. yds. concrete, at \$5.25 to \$8.....	15,045
6,822 sq. yds. plastering, at \$0.25.....	1,706
695 sq. yds. granolithic walk, at \$0.21.....	1,313
Seeding	21
Ratling	426
Miscellaneous extras	462
Total	\$30,462

For detailed cost of the concrete lining and plastering, see the following section.

The gate chamber cost \$7,765.

Cost of Concrete Lining and Plastering a Reservoir, Forbes Hill, Mass.—Mr. C. M. Saville is authority for the following cost data on the Forbes Hill Reservoir, Quincy, Mass., built by contract in 1900-1901. Common laborers were paid \$1.50 per 10-hr. day. There were four classes of concrete used, and their itemized costs were as follows:

Class "A"; Concrete 1:2½:4.

1.35 bbl. Portland cement, at \$2.23.....	\$3.01
0.46 cu. yd. sand, at \$1.13.....	.52
0.74 cu. yd. stone, at \$1.13.....	.84
25 ft. B. M. lumber for forms, at \$20.00 per M..	.50
Labor, on forms59
Labor, mixing and placing.....	1.15
Labor, general expenses20

Total (279 cu. yds.) per cu. yd. \$6.81

Class "B"; Concrete 1:3:6.

1.07 bbl. Portland cement, at \$2.23.....	\$2.39
0.44 cu. yd. sand, at \$1.13.....	.50
0.88 cu. yd. stone, at \$1.13.....	.99
6½ ft. B. M. lumber for forms, at \$20.00 per M..	.13
Labor, on forms21
Labor, mixing and placing97
Labor, general expenses15

Total (284 cu. yds.) per cu. yd. \$5.34

Class "C"; Concrete 1:2:5

1.25 bbl. natural cement, at \$1.08.....	\$1.35
0.34 cu. yd. sand, at \$1.02.....	.35
0.86 cu. yd. stone, at \$1.57.....	1.35
4½ ft. B. M. lumber, at \$20.00 per M.....	.08
Labor, on forms10
Labor, mixing and placing.....	1.17
Labor, general expenses08

Total (400 cu. yds.) per cu. yd. \$4.49

floor to spring line, 2 ft. thick for 5 ft. below the spring line and 3.33 ft. thick at the base. The roof arches have a 12 ft. clear span, 2½-ft. rise, and are 6 ins. thick at the crown. The earth covering on the roof is 2½ ft. thick at the walls and 3 ft. thick at the center. The centers used in building the concrete roof cost the contractor 22½ cts. per sq. ft. if used only once. He attempted to use them several times, but the braces against some of the brick piers were carelessly removed after a portion of the centers had been taken down, and the lateral thrust of the concrete arches overthrew the piers and caused a loss of part of the roof. The cost of the reservoir to the city was \$10,415.

Some of the items were as follows.

2,446 cu. yds. earth excavation.
310 cu. yds. rubble masonry
503 cu. yds. concrete masonry.
61 cu. yds. brick masonry
143 cu. yds. gravel on roof.
439 cu. yds. loam on roof.

A steel ring was embedded in the circular wall. The weight required for such a steel ring is given by the following formula:

$$W = 0.912 D^2.$$

D being the diameter of reservoir in feet, and W being the total weight in pounds, including an allowance of 25% for splicing and rivets.

In Table XV, Mr. Coffin gives the estimated cost of covered reservoirs built with economic dimensions, and of the same general design as the one at Wellesley, Mass.

TABLE XV.—COST OF COVERED RESERVOIRS.

Capacity Gallons.	—Round Reservoirs.—			—Square Reservoirs.—		
	Diam.	Depth.	Cost.	Side.	Depth.	Cost.
250,000	60	12	\$ 4,700	64.5	11	\$ 4,800
500,000	75	16	7,800	69.5	14	8,100
750,000	88	17	10,500	79.5	16	11,000
1,000,000	98	18	12,900	88.5	17	13,600
1,250,000	106½	19	15,200	99.5	17	16,000
1,500,000	115½	19	17,600	106.0	18	18,400
1,750,000	120	21	20,000	111.5	19	21,700
2,000,000	125	22	22,000	118.5	19	22,900
2,500,000	134	24	26,200	130.0	20	27,300
3,000,000	144	25	30,200	142.5	20	31,500
4,000,000	166*	25*	37,900	153.5	23	39,500
5,000,000	186*	25*	45,600	165*	25*	47,400

*These are not exactly the most economic dimensions.

The above estimates are based upon the following unit prices:

Earth excavation, per cu. yd.	\$ 0.50
Concrete walls, floors and pier foundations.	6.00
Concrete roof, per cu. yd.	6.50
Brickwork in piers, per cu. yd.	13.00
Plastering walls, per sq. yd.	0.25
Plastering floor, per sq. yd.	0.15
Gravel on roof arches, per cu. yd.	1.00
Steel ring, per lb.	0.05
Centers, per sq. ft. of reservoir area.	0.15

Cost of Small Covered Reservoir, Portersville, Calif.—Mr. Phillip E. Harrows gives the following data relative to a 100,000-gal. reservoir built in 1904 for the waterworks at Portersville, Cal.

The work was done by day labor, at 20 cts. per hr. The reservoir is 50 ft. diam., 7 ft. deep, lined with 4 ins. of concrete on the bottom and 12 ins. on the sides. It is roofed with 2 x 10-in. stringers, 4 ft. apart, supporting 1½-in. plank. The ends of the stringers rested on the concrete walls and on an 8 x 10-in. girder which ran across the center of the reservoir and was supported on a pier at the center. The excavated material was a heavy clay, loaded with picks and shovels into wagons. The excavation averaged 4 ft. deep, and the embankment was 4 ft. high.

The cost was as follows:

330 cu. yds. excavation, at 58.6 cts.	\$ 191.08
300 cu. yds. hauled ¾ mi., at 20.4 cts.	53.98
75 cu. yds. concrete (labor, \$3.03, and materials, \$5.31), at \$8.34	624.74
35 squares plaster finish at \$2.92	102.45
4,000 ft. B. M. roof, at \$45.49	181.98
Trimming outer slopes	18.70
Total	\$1,172.91

The plaster labor cost \$0.57 per square on the bottom and \$1.12 on the vertical sides.

The roof labor cost \$12.43 per M, wages of carpenters being \$3 to \$4.37.

Cost of a Covered Reinforced Concrete Reservoir.—In Gillette and Hill's "Concrete Construction—Methods and Cost," pp. 589 to 597, the design of a small, square, covered reservoir (30 x 31 ft.) is given, together with detailed costs and methods of construction, of which the following is a very brief abstract. The reservoir is 12 ft. deep and holds 75,000 gals. There were 580 cu. yds. of earth excavation and 83 cu. yds. of concrete. The cost of the concrete was:

1½ bbls. cement, at \$1.12	\$ 1.49
1 cu. yd. stone	1.86
¼ cu. yd. sand	0.60
Steel for reinforcement	4.76
Forms, 100 ft. B. M., at \$18.30	1.85
Labor on forms	2.41
Labor on concrete and steel	2.65

Total\$15.62

The excavation cost the contractor 90 cts. per cu. yd.

The total cost of the reservoir to the contractor was \$2,362, but it leaked so badly that he was subsequently compelled to excavate all around and build a brick wall (1 brick thick) a few inches from the concrete and fill in between with rich cement mortar. This additional and unexpected work cost \$1,240 for labor and materials.

Cost of a Covered Reinforced Concrete Reservoir, Fort Meade, S. D.*—Mr. Samuel H. Lea gives the following:

The construction of a 500,000-gallon reinforced concrete reservoir

**Engineering-Contracting*, Feb. 27, 1907.

at Fort Meade, S. D., while not comprising any features of unusual interest, was, nevertheless, an interesting work from an engineering as well as an economical point of view. The writer, who was in direct charge of the work, believes that an analysis of the various items of cost and a brief description of the methods employed will be of interest to engineers and others interested in concrete work.

The general design of the structure was furnished by the Quartermaster-General, U. S. Army, and the details of reinforcement were worked out by the firms offering bids. The successful bidder submitted a design embodying the use of expanded metal and corrugated bars, this form of reinforcement being furnished by the
